On the whole employers were enthusiastic about the effects of canteen meals on production. In one experiment large vitamin supplements reduced absenteeism. In Canada in 1945 it was found that over half the employees in plants inspected carried packed lunches and only 12% had hot lunches in the factory canteens; in the U.S.A. in 1944 nearly half ate packed lunches. In Great Britain in 1944 just over a quarter of those factories employing over 500 ate hot meals in the canteens; in March of that year 17 million lunches of the meat-and-two-vegetable type were served each week. In the U.S.A. only 27% of the workers had a lunch break of over half an hour. In Canada the lunch time varied from 15 minutes to 1 hour and 20 minutes; in some factories the workers did not leave their machines. The number who continued to eat packed lunches was therefore not surprising. Dr. Donald Hunter may note a photograph of painters in a Canadian aircraft works eating and drinking their protective milk at the bench among the paint pots. A study of the food eaten in logging camps showed that each man received the equivalent of 5,311 to 6,425 calories a day.

J. R. MARRACK.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Ellis's Anatomy.* Revised and Edited by J. A. Keen, M.B., F.R.C.S. (Pp. 487. 42s.) London: John Murray. 1946.

A manual of dissection for medical students; includes new material on applied anatomy.

*Practical Emulsions.* By H. Bennett. 2nd ed. (Pp. 563. 48s.) Brooklyn, N.Y.: Chemical Publishing Co., Inc. London: Chapman and Hall, Ltd. 1947.

A textbook of colloid chemistry for the practical worker

*Arthritis and Related Conditions.* Edited by T. F. Each, M.D., F.A.C.P. (Pp. 472. \$6.50 or 36s.) Philadelphia: F. A. Davis Company. London: H. K. Lewis. 1947.

An account of arthritides for the general practitioner, with emphasis on the details of treatment.

*Statistical Methods in Research and Production.* Edited by Owen L. Davies, M.Sc., Ph.D. (Pp. 292. 28s.) Published for Imperial Chemical Industries, Limited. London: Oliver and Boyd. 1947.

A practical handbook of statistical methods for scientific and industrial research workers.

*Artificial Respiration: The Schafer Method.* 15th ed. (Pp. 71. 1s. 6d.) London: The Royal Life Saving Society. 1947.

An illustrated manual on artificial respiration with an outline of the relevant physiology.

*He Loved Freedom.* By Sidney Fairway.<sup>1</sup> (Pp. 224. 9s. 6d.) London: Stanley Paul and Co., Ltd. 1947.

A novel by the late Dr. S. H. Daukes (Sept. 13, p. 435).

*Synopsis of Allergy.* By H. L. Alexander, A.B., M.D. 2nd ed. (Pp. 255. 18s.) London: Henry Kimpton. 1947.

Includes new material on the antihistamine drugs.

*The Electrical Factor in Metabolism.* By W. N. Abbott, M.C., M.B., B.S., and E. F. Fowler, M.B., Ch.B. 3rd ed. Wellington, New Zealand. 1945.

A collection of articles, including discussion of the Scalebuoy apparatus.

*Does Science Deny God?* By C. L. Bishop. (Pp. 121. 6s.) Bournemouth and London: William Earl and Co. 1947.

The author's "present object is to show that scientific knowledge is not antagonistic to a belief in the existence of a universal mind or force."

*Creation's Heir.* By Harold Dearden. (Pp. 160. 12s. 6d.) London: Andrew Melrose, Limited.

A discussion of the mind, its effective or clumsy thinking, with suggested remedies for various maladies, social as well as mental.

*Science in Transition.* By A. W. Haslett. (Pp. 244. 10s. 6d.) London: Christopher Johnson. 1947.

An account of recent scientific developments, particularly those made during the war.

*Food and Health.* By Henry C. Sherman. (Pp. 290. 20s.) New York: The Macmillan Company. 1947.

An account of food and its utilization in the body, intended for housewives and dietitians.

*Rheumatism and Soft Tissue Injuries.* By James Cyriax, M.D., B.Ch. (Pp. 410. 42s.) London: Hamish Hamilton. 1947.

Discusses painful soft-tissue lesions resulting from injury or commonly termed "rheumatic," their accurate localization, diagnosis, and treatment.

*Design of Accounts.* By F. Sewell Bray, F.C.A., F.S.A.A., and H. Basil Sheasby, F.C.A., F.S.A.A. 2nd ed. (Pp. 270. 12s. 6d.) London: Geoffrey Cumberlege. 1947.

Describes the proper preparation of accounts and how to present them.

*Victory Over Pain.* By Victor Robinson, M.D. (Pp. 338. 16s.) London: Sigma Books. 1947.

A history of the development of anaesthesia.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 27 1947

## WORLD MEDICAL ASSOCIATION

A new international medical society—the World Medical Association—was formed on Thursday, Sept. 18, and on the afternoon of that day held the first meeting of its General Assembly. It is, in effect, the direct successor to the A.P.I.M.—Association Professionnelle Internationale des Médecins. The past few months have witnessed a revival of many international medical and scientific congresses, culminating this month in the remarkably successful meetings in London of the International Conference of Physicians, presided over by Lord Moran, and of the International Society of Surgery, presided over by Dr. Leopold Mayer. The two congresses in London were distinguished by the presence of eminent physicians and surgeons from all over the world, by the high level of the scientific contributions made at them, and by a cordial atmosphere of friendliness which surmounted all difficulties of race and language. The meeting of the World Medical Association in Paris last week was unfortunately not permeated with the same spirit. Although it added to its six laudable objects a seventh—“To promote world peace”—peace at the meeting itself was on many occasions preserved with difficulty. It may, however, turn out to be a good thing that this new organization was formed in an atmosphere free from illusions. But it would be wrong to put a gloss upon the facts or to pretend that those present left the meeting with the feeling that the foundation-stones had been well and truly laid.

The meeting was divided into two parts. The first was a Conference of Delegates of National Medical Associations, which was presided over by Sir Hugh Lett, Dr. Charles Hill and Dr. P. Cibré acting as joint secretaries. The proceedings began with a speech by the French Minister of Health, who welcomed the presence in Paris of the medical representatives of close on fifty nations. He said that the State had to concern itself with the physical and moral condition of the citizen, and he looked forward to hearing the results of the deliberation of the meeting on the relationship between the State and the doctor—a deliberation which unfortunately did not take place, as the protracted discussions on procedure and other matters did not allow time for the debate on this subject which should have been opened on Thursday by Dr. Guy Dain: there was time only for a series of short statements on Saturday afternoon. After the Minister of Health left, Dr. T. C. Routley gave a report of the activities of the Organizing Committee and hoped that the Assembly would approve the results of its labours. The task of the first part of the meeting was to decide on the Articles and By-laws of the proposed World Medical Association. These had been drawn up by the Organizing Committee and circulated to those present in English and French, the two official languages of the W.M.A., to which by the end of the meeting it was agreed that Spanish should be added. It soon became evident that many of the delegates of the 48

countries represented wanted to modify some of Articles and By-laws, and that the Conference did not succeed in agreeing upon these was due principally to patience and tactful handling of the meeting by Sir H. Lett and the unruffled demeanour of Dr. Routley. The delegate from Cuba, for example, wanted to change the name of the W.M.A., and the delegate from Turkey proposed that pharmacists and dentists should be admitted to membership; the Bulgarian delegate wanted to add another object—namely, that the W.M.A. should promote surgery and prophylactic medicine.

It should, perhaps, be pointed out that the two principal objects of the W.M.A. are the first and the third, which are thus:

- (i) To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available;
- (iii) To study and report on the professional problems which confront the medical profession in the different countries.

The W.M.A., in other words, would appear to be concerned principally with all those matters which are summed up under the term “medical politics.” There was some confusion about whether the W.M.A. should be composed of representatives of different countries or of different national medical associations. If one country could secure the admission of delegates from several national medical associations then its votes would outnumber those of a country with representatives from only one national medical association. It was decided that each national medical association should have two votes, one for each of the delegates, and two votes for the one delegate if the second was unable to be present. Eligibility for membership was defined by Article 5, as follows:

- (i) Those medical associations which sent delegates as observers to the International Medical Conference in London in September, 1946; and
- (ii) Any other national or territorial medical association which is fully representative of the medical profession in a country or territory or of the members of the medical profession of a recognized ethnic group in its country or territory.

After prolonged discussion the latter sub-section was passed unaltered.

By the end of the first day the Conference had been unable to finish its discussions on the Articles and By-laws. This was due principally to the frequent intervention of the delegates of the South American countries, who acted as a bloc under the leadership of the delegate of the Medical Association of Costa Rica. It was highly regrettable that the fashion of voting by a bloc was introduced at the meeting and it seemed that the meeting was beginning to imitate some of the worst features of U.N.O. At one point the meeting was persuaded to vote in favour of a resolution that the Secretariat should be members of the Executive Council, but on the second day it had the sense to reject the absurdity of this decision, and agreed on a motion that Dr. Dain should act as the Secretary of the Council and not as a member of it. In various discussions on the By-laws it became clear that the Conference was anxious that the General Assembly of the W.M.A. should not devolve too much of its responsibility upon the Council. The Indian representatives, who made more than one helpful contribution to the discussions, pointed out some anomalies between the By-laws and the Articles

essed, what needed stressing, that the unit of membership a national medical association and not a country.

It was not until 3.30 p.m. on September 18 that the discussion on the Articles and By-laws came to an end. But at least the meeting had the satisfaction of thrashing out points of difficulties, and just how acute some of these points were may be illustrated by the fact that one By-law was by vote successively deleted, then restored, and then deleted again.

At the first meeting of the World Medical Association proper, which occupied the second half of the Proceedings, Dr. Charles Hill was appointed Acting Honorary Secretary, and Dr. Routley, who took the Chair until a new President was elected, observed that it was necessary to take the credentials of those delegates who had not yet presented them. This formal and routine procedure led to a series of regrettable incidents which were finally resolved in a manner which made it look as if the General Assembly was adopting By-law No. 44, as follows: "A Delegate shall be a person who is medically qualified and a member of the association he represents, and he shall be ordinarily resident in the territory of that association." At one point all the delegates of the South American countries left the chamber and subsequently returned, deftly piloted by Dr. Cibré. Prof. Marquis, who is Director of the School of Medicine of Rennes, was elected the first President, and only conducted the first meeting of the General Assembly. At the end of the meeting Dr. Routley was elected chairman of the Council.

With all the delegates once more present in the chamber the Treasurer, Dr. Leuch, of Switzerland, presented his report. He pointed out that the funds from the subscriptions of the various national member associations were inadequate for the tasks of the W.M.A. and reported to the meeting the generous offer made by the American delegates of \$50,000 a year for five years. To this gift certain conditions were attached, and because of these conditions feelings once more ran high. It is not unreasonable or unusual for conditions to be attached to a gift of money; yet some delegates felt that the gift should be free from conditions. Others objected to certain of the conditions. They were put to the meeting in the form of a recommendation by the Chairman of the Organizing Committee. Briefly, they were that the money should be used for (i) the salaries of the Secretary and other officials of the clerical staff, (ii) the rent and rates of the headquarters office, and (iii) the cost of publication of the W.M.A.'s official bulletin or journal. (It was subsequently agreed by the meeting that the money should also be used for the travelling expenses of the Council.) Another condition was that the Headquarters of the W.M.A. should be in North America, the exact location to be determined by Council. Still another condition was that the Council be instructed to work out a scheme of associate membership; this was subsequently altered to the effect that the Council should explore the possibility of arranging for gift funds for the W.M.A. to be free of income tax. Dr. L. H. Bauer, one of the delegates from the U.S.A., gave to the meeting a clear exposition of the circumstances of the gift. It was, he emphasized, not a gift from his member association, the American Medical Association, which had many heavy financial commitments. The money had been offered by friends of the A.M.A.—principally, it appeared, industrialists anxious to promote

the interests of the W.M.A. The disbursement of the money would be under the control of a committee in the U.S.A. composed of five doctors and four laymen. If the business donors could be admitted under a scheme of associate membership, Dr. Bauer said, they should have the right to attend meetings but not, of course, the right to vote. Dr. Bauer finally said that in certain circumstances, which would, however, be highly unlikely, the American finance committee might withdraw the gift. The first speech of opposition to this proposal was made by Dr. P. B. Mukerji, President of the Indian Medical Association. He expressed his appreciation of the generosity of those who had made such a large sum of money available to the W.M.A. but doubted whether it should be accepted under such terms. He felt that the W.M.A. should work out its own salvation even if it meant that much of the work would have to continue to be done on a voluntary basis. The debate on this controversial subject continued on the Friday. Irrespective of the conditions of the gift, it was decided that the Headquarters of the Secretariat should be in North America. This decision having been taken, the debate continued on whether to accept the American gift with amendments to the terms. The important amendment was that which deleted the reference to working out a scheme of associate membership. By the counting of hands 31 voted for accepting the gift, and 32 against. A recount being necessary, it was suggested that this was an unsatisfactory method of arriving at a conclusion, and the Assembly departed for a visit to Versailles, on the agreement that a further and more strictly controlled vote should be taken on the following day, when, some members abstaining from voting, the General Assembly voted in favour of accepting the handsome gift of \$50,000 a year for five years.

If this gift had not been accepted it is doubtful whether the W.M.A. would have remained in being. It is perhaps a commentary on the unsettled economy of the world that the W.M.A., which represents some 500,000 doctors, could not raise sufficient funds to carry on its own work unaided.

It remains to be said that in the midst of controversy on procedure and finance the General Assembly entered into a non-controversial atmosphere when it condemned the crimes committed by German doctors. It had before it a document drawn up by the Council of the B.M.A. under the heading "War Crimes and Medicine," and it listened in sympathy to an address on this subject by Prof. Charles Richet, who had himself been in a German concentration camp. He was followed by one of the Greek delegates, who, at the end of his address, asked the meeting to stand in memory of the Greek doctors killed by the enemy. It was finally agreed that German delegates should not be admitted to the W.M.A. until organized medicine in Germany condemned the past criminal acts of German doctors.

We have tried to give a faithful account of what happened last week at this highly important conference held in Paris in the Domus Medica, the Headquarters of the Confédération des Syndicats Médicaux Français, which throughout the Proceedings acted as a most generous host. It is important, we believe, that the various difficulties attending the establishment of the W.M.A. should be known so as to be understood. It had set its hand to a great task, and if it is to achieve its highly important objects it will have to secure the good will of the various national

medical associations in all parts of the world. If these associations, through their delegates, come to the meetings of the Council and of the General Assembly in a factious mood then the prospects of success are not bright. Much, of course, will depend upon the hard work, tact, and ability of the permanent Secretary, who has yet to be chosen.

## HAEMATEMESIS

Haematemesis is a subject which can always be relied upon to cause a lively discussion at any medical meeting, while in the literature comment and counter comment have been at times acrimonious. In his Goulstonian Lectures for 1947, the publication of which we conclude in the opening pages of this issue, Avery Jones has given a comprehensive and up-to-date account of the subject based on a personal series of 687 cases admitted to a municipal hospital between June, 1940, and January, 1947. He exposes certain fallacies which have crept into modern thought, and he has important observations to make upon what must always be the core of the problem—the early recognition and treatment of those cases in which the bleeding is likely to be dangerous.

There are errors in the statistics of haematemesis which are not generally realized. The literature is comprised of three types of series—mass hospital statistics, collected series, and individual series. Only the last of these are acceptable, and they may be misleading because of the small numbers recorded, the different criteria of diagnosis used, and the type of case which is excluded. Surgical cases are commonly discarded, and in some series even fatal cases are ruled out, on account of complications which in many instances should be attributed to the treatment. A further drawback is that small series are often published in order to illustrate a particular form of therapy, and, as such, they will record successful rather than unsuccessful methods, with a consequent distortion of the over-all mortality. Four major variables must be considered in any discussion on haematemesis: social status, age, sex, and the type and position of the lesion. Ignorance of any one of these factors may lead to muddled thinking. For instance, the surgeon may reassure himself, and his patients, that the mortality from gastrectomy for haemorrhage is low, whereas analysis will show that this is only true below the age of 40 years, after which age the hazard is much increased.

There was a considerable increase in the number of deaths from haematemesis between the wars; it reached a maximum in the early 1930's and has since declined. This increase may be attributed to the virtual disappearance of acute ulcers among young women and their replacement by chronic ulcers in men over 40. The subsequent decrease in mortality Avery Jones considers to be due to the introduction of the drip blood transfusion and to the use of liberal feeding. Some workers have emphasized the possible dangers of blood transfusion in haematemesis. They claim that the blood pressure may be raised unduly and bleeding restarted. The present series gives no support to such a view. Provided that the known dangers are guarded against, transfusion is recommended, the aim being to maintain the haemoglobin above 40%. This is a view which is generally accepted to-day. Cautious transfusion is regarded as an insurance against disaster should haemor-

rhage recur, and it ensures that the patient is better able to stand operation if this should be required.

Copious feeding for patients who have recently had brisk haemorrhage from the stomach or duodenum is first advocated by Meulengracht, and in this country the modification elaborated by Witts is becoming increasingly popular. It is maintained that a purée diet does not increase the risk of recurrent bleeding and that it improves the patient's general condition and so promotes healing. Avery Jones finds no evidence to suggest that liberal feeding, any more than blood transfusion, causes recurrent haemorrhage. But in 32 out of the 45 cases examined post mortem an exposed vessel was seen. These patients had died after several recurrent bleedings, and it is pointed out that at operation these pulsating vessels spurt with blood when they are touched; may they not do so when semi-solid food moves up against them? It is not always possible to give purée right from the beginning of treatment, because of the poor general condition of the patient, or because of nausea, or perhaps because of the persistence of pain—always a serious feature. In such circumstances Avery Jones recommends two-hourly feeds of 7 oz. (200 ml.) of milk. This is a sound suggestion for, as Izod Bennett and his colleagues<sup>1</sup> pointed out, in haematemesis the digestive functions are gravely disorganized, and it may be unwise to demand from the diseased organ the additional work which the digestion of semi-solids may entail.

Whatever regime is adopted the prevention of dehydration is important, and Marriott's dictum,<sup>2</sup> that a patient should pass every eight hours a pint of urine (568 ml.) containing 5 g. of chlorides per litre, should be remembered. From a study of the post-mortem records of patients who died before the introduction of massive transfusion and early feeding Avery Jones concludes that dehydration was the cause of death in many, though the high levels of the blood urea suggest another possibility. Darmady<sup>3</sup> has shown that the renal changes observed in traumatic uraemia may also be found in any condition in which a state of shock occurs. Such changes have been described in haematemesis, and it may well be that early and adequate resuscitation is even more important than early feeding.

A gastroscopic study was made of cases in which there was no radiological proof of peptic ulcer, and the results are of considerable interest. Avery Jones is at pains to explain that early gastroscopy is not recommended as a routine measure, but here it was undertaken as part of "a definite clinical investigation." The examination was successful in 116 out of 217 cases. In 30 the mucosa of the stomach was found to be normal; in 86 there were pathological changes, and this group included 65 cases in which there was a gastric ulcer. Of the acute ulcers 3 were superficial, flat lesions, with little or no surrounding oedema. There were no generalized changes in the gastric mucosa, and in 5 instances the ulcer was accompanied by a histamine-fast achlorhydria. These acute ulcers seldom proved fatal. In some cases they gave rise to no symptoms but more usually there was a history of bouts of epigastric pain lasting from a few days to a few weeks. These lesions cannot be shown radiologically, and this study emphasizes yet again that a negative skiagram in a patient with

<sup>1</sup> *Lancet*, 1942, 1, 551.

<sup>2</sup> *British Medical Journal*, 1947, 1, 328.

<sup>3</sup> *Brit. J. Surg.*, 1946, 34, 262.

suggestive symptoms must not be taken as evidence against peptic ulceration.

The many discussions that have taken place on the subject of haematemesis have cleared the air to a considerable extent, and most clinicians would now agree on the importance of reassuring the patient, of rapid resuscitation, and of the maintenance of a safe haemoglobin level, with the prevention of dehydration. Attention should now be directed to the best means of diagnosing early and treating adequately those patients who have large indurated ulcerations in the floor of which lies a thickened and eroded vessel. Age appears to be important. Below 45 years recovery is probable, even though brisk bleeding recurs after admission to hospital. Good clinical evidence of chronic ulceration is to be expected: persistence of pain is suggestive, as is evidence of general arteriosclerosis, and a history of recurrent haemorrhage is characteristic. In many of these cases there can be no argument as to the best method of treatment; complications such as great age, severe emaciation, and cardiac or pulmonary disease will preclude surgical measures. In others, however, surgery offers considerable hope. Two provisos must be observed: the decision to operate must not be delayed until the patient is in *extremis*, and his general condition must be such that he may be considered to have a fair chance of standing a partial gastrectomy. Observing these rules, Avery Jones records successful operations in 6 out of 7 cases. The only fatality was in a man of 75 years. From these figures another point is made clear—the surgical skill required is of the highest order.

### PREVENTION OF CARDIAC LESIONS DUE TO DIGITALIS

When large doses of digitalis are given to animals daily for a period certain lesions of the myocardium result. It now appears that the administration of aminophylline will prevent the appearance of these lesions; this finding may have a clinical application.

The story begins with Böhner's observation<sup>1</sup> in 1934 that cats treated with large doses of digitalis glycosides show degenerative changes in their heart muscle, particularly in the papillary muscles of the left ventricle, where the muscle undergoes necrosis. Similar observations have been made by later workers.<sup>2,3</sup> Dearing, Barnes, and Essex<sup>4</sup> found such changes after giving cats an initial dose of digitoxin equal to 0.3 of the lethal dose, followed by daily doses corresponding to 0.3 to 0.6 g. digitalis leaf for a man. They observed degeneration of the myocardial fibres and haemorrhage; exudative cells appeared later, and when these disappeared the connective tissue cells proliferated. Banting and Hall<sup>5</sup> and their colleagues made two other observations. They gave dogs intravenous injections of 50 mg. acetylcholine by slow infusion into a leg vein. Curiously enough, the effect on the heart rate was acceleration, but the effects on blood pressure, on breathing, and on the intestines were those expected. The blood pressure fell, and there was dyspnoea, cyanosis, salivation, vomiting, and diarrhoea. These large doses were given daily until the animals died. Their hearts showed permanent damage—hyaline degeneration and some thrombosis

in the coronary vessels. Acetylcholine constricts the coronaries, and Banting and Hall suggested that the degeneration was due to this constriction. They produced similar cardiac lesions by chronic stimulation of the vagus (for 31–70 hours) under light nembutal anaesthesia; the heart rate was decreased, but the other effects were the same as those following the injection of acetylcholine. Here again they believed that the myocardial degeneration was due to coronary constriction.

Kyser, Ginsberg, and Gilbert<sup>7</sup> considered that the myocardial degeneration caused by large doses of digitalis might also be due to coronary constriction, and might therefore be prevented if the digitalis was given together with a powerful coronary-dilator. They gave a digitalis preparation called "digiglusin" to seven dogs for periods varying from 21 to 86 days; in all seven they observed myocardial degeneration. To five dogs they gave digiglusin together with aminophylline (about 80% theophylline and about 12% ethylene-diamine) 3.75 gr. (0.25 g.) twice daily. The hearts of these dogs after 17 to 37 days were almost normal and practically free from degenerative changes. Theobromine sodium acetate protected three out of five dogs but not the other two. Papaverine hydrochloride had no protective action. The evidence suggests that myocardial degeneration does arise from coronary constriction and that theophylline can prevent it when such degeneration is caused by excess of digitalis.

### ATTACK ON DISSEMINATED SCLEROSIS

Research into the aetiology of disseminated sclerosis is attracting attention again, and there has recently been set up in the U.S.A. an organization called the Association for Advancement of Research on Multiple Sclerosis, Inc. This is a lay body, financed from voluntary sources, under the honorary chairmanship of Dr. Tracy J. Putnam and with a board of medical advisers. It will collect funds for research, gather and co-ordinate information, and educate the general public. The Association proposes immediately to investigate whether the disease occurs more frequently—as the figures indicate—in the northern areas of Europe and the Western Hemisphere than in Mediterranean and tropical lands. It has also arranged to finance a three-year investigation at the Neurological Institute, New York City, into the possibility that the disease is an allergic manifestation. Among other work to be studied are that of Putnam suggesting a vascular mechanism, and the isolation by Margulis, Soloviev, and Schubladze<sup>8</sup> of a virus from cases of acute disseminated encephalomyelitis. The New York State Department of Health has offered facilities for examining the cerebrospinal fluid from cases of disseminated sclerosis. The Association will presumably also investigate the relationship, if any, between human disseminated sclerosis and swayback in lambs, reported by Russell and others.<sup>9</sup>

Many sufferers from the disease in the U.S.A. and Canada have formed clubs under the auspices of the Association to bring voluntary relief to those in need and to contribute funds for research. *A.A.R.M.S. Forward* is a bulletin supplying members with the latest information, and the Association also issues educational pamphlets. This co-operative effort by medical men and their patients is commended to those in this country who are interested. They may obtain further information from the Executive Secretary of the Association, New York Academy of Medicine Building, Fifth Avenue and 103rd Street, New York, 29.

## INTERNATIONAL SOCIETY OF SURGERY TWELFTH CONGRESS IN LONDON

(Continued from p. 467)

The congress of the International Society of Surgery continued its London meeting until Sept. 20, after which a number of the members travelled to Edinburgh to fulfil a further programme. In addition to the scientific discussions visits were paid to many London hospitals, and on the last afternoon there was a pilgrimage of homage to places connected with Hunter and Lister.

### Vascular Surgery

On Tuesday morning, before a crowded audience in the Great Hall of B.M.A. House, Prof. René Leriche (Paris) opened a discussion on the progress of vascular surgery, expounding in a masterly way the physiology and pathology of the arteries, and surgical principles and methods. He spoke particularly of the management of chronic obstruction of the large arteries of the limbs. He was followed by Dr. Sousa Pereira (Oporto), with an account of sympathetic innervation and the treatment of embolism and cerebral thrombosis, and also the influence of sympathetic innervation on the development of collateral circulation.

Dr. J. R. Veal (Washington) said that some years ago in the States it was found that in the group of diabetic and arteriosclerotic patients who had undergone leg amputation for vascular gangrene the mortality following operation was about 40%, and the most important factor was pulmonary complications. Further study suggested that pulmonary embolism was the cause in the majority of cases, but such pulmonary embolism had been almost completely eliminated, and the mortality brought down to 10-13% by the precaution of a preliminary higher ligation of the saphenous vein. The unoperated leg often also gave trouble, and now the practice was to make a bilateral ligation of the saphenous vein in these patients, with a further reduction in mortality.

Mr. Dickson Wright (London) reported two cases of thromboangiitis obliterans with sudden onset of claudication. Arteriography showed that the femoral artery was obstructed only for 3.8 cm. in the one case and 5 cm. in the other just above the knee, and the rest of the arterial system seemed to be in good order. In both cases he dissected the body of the artery and interposed a graft from the saphenous vein. He took the vein which lay alongside the thrombosed artery, moved it slightly over without detaching it from its surroundings, and placed it between the two ends of the artery. The results were perfect, and the patients had done extremely well and had lost their claudication.

Dr. L. G. Herrmann (Cincinnati) described the use of what was known as the vitallium cuff in reconstructing the circulation after arterial injuries caused by gunshot or stab wounds; Prof. Dos Santos (Lisbon) and others discussed special techniques, and Dr. Servelle (Paris) gave a remarkable demonstration of contrast methods in arteriography, venography, and lymphography.

### Surgical Treatment of Congenital Pulmonary Stenosis

The congress gave an ovation to Prof. Alfred Blalock, of Johns Hopkins Hospital, Baltimore, who gave a more extended presentation of his operation for congenital pulmonary stenosis than he had given to the International Conference of Physicians the previous week. Up to 1938 there was no satisfactory treatment for any type of congenital heart disease. Since then an advance had been made in each of the major groups—patent ductus arteriosus, coarctation, and pulmonary stenosis. The tetralogy of Fallot accounted for about 75% of cyanotic children over the age of two. The object of his operation was to anastomose a systemic vessel in which there was a higher pressure and in which also there was unoxygenated blood to one of the two pulmonary arteries in which the pressure was low. On the right side either the innominate or the carotid or the subclavian could be used, and on the left side either the left subclavian or possibly the side of the aorta. The point was to connect the systemic and pulmonary circulations. He usually carried out an end-to-side anastomosis so that the blood could go to both lungs instead of only to one, but occasionally,

when a pulmonary artery was encountered which was too small to admit the end-to-side, an end-to-end anastomosis had to be done. Most of the operative procedures had been performed on the right side for the reason that the innominate came off the right in most patients, and he preferred to use the subclavian branch of the innominate rather than the subclavian which arose directly from the aorta, because it made a better angle. In 25% of these patients the aorta descended on the right instead of on the left, in which case the innominate was on the left and an incision had to be made on that side if it was desired to use the subclavian branch of the innominate.

Prof. Blalock showed a film of the entire operation—the ligation of the azygos vein; the division of the mediastinal pleura; the exposure of the right pulmonary artery, the exposure of the innominate artery from under the superior vena cava, and the anastomosis between the end of the subclavian and the side of the pulmonary. He said that in half the patients the procedure was as easy as it appeared on the screen, in a number it was rather more difficult, and in a few it was very difficult indeed. By a fortnight after operation the cyanosis had usually disappeared; the disappearance of the clubbing of the fingers occurred later. In 474 cases submitted to operation there had been 86 deaths, but 18 of the deaths followed exploratory thoracotomies in which it had been impossible to find a pulmonary artery. In the last 38 successive cases there had been no death. Most of the patients who had survived the operative procedure had markedly improved, and some of them who could walk only a few steps before operation were now able to walk miles. He showed two patients, a girl aged 3 and a boy aged 9, who had recently undergone this operation. They appeared quite normal children.

Dr. P. Sandblom (Stockholm) said that this was one of the most brilliant and exciting advances in modern surgery. Stockholm Blalock's operation had been carried out in a few cases; there had been three deaths. Unlike Blalock, he always heparinized the patient. He thought it wise to start that way; no doubt when the technique had been fully mastered heparin need be used only as Blalock used it—very rarely. Although it might be thought a risky operation, when the case before and after operation were seen there was every encouragement to pursue it.

### War Injuries of the Lungs

On Wednesday Dr. Bastos-Ansart (Barcelona), speaking in Spanish, described the results of early operation on pulmonary war wounds. His experience was based on the Spanish Civil War, where surgeons had to work under special difficulties, small teams and with sparse equipment, having largely to depend upon their wit in improvisation, though they certainly had the advantage of being able to get to their patients in very short time. In cases in which the wounds were limited to the lungs an extremely conservative surgery was practised. The lung itself was able very well to deal with infection. Aspiration was carried out, but only partially, and his experience was that bleeding tended to restart as a result of such aspiration. If, of course, there were multiple wounds immediate surgical intervention was made. Dr. Rudolf Matas, former president of the congress, who interpreted Dr. Bastos-Ansart's lengthy paper, described it as a classic in military surgery as practised in the war, and he hoped it would be translated for the benefit of surgeons all over the world.

A graphic exposition of the treatment of gunshot wounds of the chest as encountered on the Italian front was given by Mr. A. L. D'Abreu (Birmingham), who said that his experience covered 2,000 such cases in soldiers. Towards the latter part of the war it became evident that the treatment of such wounds surgically and administratively, fell into two stages. In the first stage the object was to save the patient's life, which was done by blood transfusion, oxygen therapy, meticulous excision of the chest wall wound, and other measures. In the second stage rehabilitation was undertaken, with prophylaxis against sepsis or treatment of sepsis if such was still present. In the battle of the Sangro, before this two-stage method was established, in a series of 260 chest wounds the empyema rate was over 30% and the mortality rate was 5.7%. Later, in the "Gothic Line" battle, by which time the two-stage treatment was organized, out of 373 cases the empyema rate was 12%, and the mortality 1.4%; and later still, in the battle for the Po Valley, where

When there is a need for a dietary supplement 'Wyamin' Capsules will supply the essential vitamins in a readily assimilable form.

Each capsule contains not less than: Vitamin A, 4,500 Int. units; Vitamin D, 675 Int. units; Vitamin B<sub>1</sub>, 100 Int. units; Vitamin B<sub>2</sub> Complex containing Lactoflavin, 50 gamma; Vitamin C, 100 Int. units; Nicotinamide, 10 mg.

## THE RATIONAL TONIC

The effective utilisation of food and the maintenance of full health and vigour are impossible in the absence of an adequate supply of all members of the vitamin B group, the average intake of which is probably lower in present circumstances than that of any of the other vitamins. Livogen, which provides all the members of the vitamin B group contained in yeast extract, together with liver extract, is the rational tonic for all patients whose dietary is lacking in these essential factors or who are subjected to unwonted strain. Further information is available on request.

A MAJOR IMPROVEMENT IN BABY SKIN

## Introducing Johnson's BABY LOTION

ANTISEPTIC

leaves a  
discontinuous film . . .  
helps to reduce infant  
skin irritations

Johnson's Baby Lotion is a smooth, snow-white, antiseptic lotion, an oil-in-water emulsion, homogenised under pressure permit extreme dispersion. It leaves a *discontinuous* film on the skin, enabling perspiration to escape and thereby helping to prevent irritation. This also materially reduces the incidence of heat rash. Johnson's Baby Lotion has been subjected to extensive laboratory and clinical tests and has proved itself a big step forward in baby skin care.

Makers of the famous Johnson's Baby Powder

JOHNSON & JOHNSON (GT. BRITAIN) LTD., SLOUGH AND GARGRA

the conditions from the point of the view of the Allied armies were entirely favourable, the empyema rate fell further to 7.6% and the mortality to 1%. In 839 cases in which haemothorax was a major problem, all treated by early aspiration, infection (empyema) occurred in 214, and clotting in 73. Strenuous endeavours were made to get normal movement of the chest, and the clot was removed by pulmonary decortication, with very gratifying results. As the war proceeded the surgeons in the British and American armies more and more favoured a thoracic approach to abdomino-thoracic wounds, provided they were sure that the abdominal injury was in the right or left upper quadrant of the abdomen.

Mr. D'Abreu was unable to look without apprehension on the lodgment of foreign bodies in the thorax. He had seen haemothoraces and empyemata develop in consequence. Most foreign bodies in the lung were in a peripheral position, and usually no deep dissection into the lung was required for their removal. It was the custom to remove foreign bodies 1 cm. in diameter within 6 to 10 days of the injury. In this way casualties were rehabilitated quickly and returned to duty. The foreign body which was partly in the lung and partly in the vertebral column was a special problem. All foreign bodies shown radiologically to be in contact with the vertebral column were removed; their retention was likely to give rise to osteomyelitis. Of 221 cases with foreign bodies in the lung 100 were operated on and the foreign bodies removed; in the remainder the foreign bodies were usually very small. Of 49 foreign bodies in the pleura 44 were removed. Altogether the new techniques practised in the recent war had enabled them to deal with complicated haemothoraces which in the previous war had left the patients with crippled chests; the surgery of foreign bodies had been made safer and more effective; and, finally, penicillin was of very great help in dealing with infection.

#### Operative Treatment of Fractures

A very unwieldy discussion took place on this subject, which was too large for one session. The subject was introduced by Prof. R. Danis (Brussels), who showed a film illustrating the uses of a special fracture operating table in his clinic and of various screws and bolts and other devices in fracture treatment. The film also showed the making of a special inlay splint and the application of an instrument called a coaptor for the adjustment of the ends of the fractured bone and the encouragement of good callus formation.

He was followed by Dr. D. Phenister (Chicago), who limited his remarks to ununited fractures. In the majority of cases, he said, the fragments were in relatively good position and there was no need for reduction. In such cases it was not necessary to break down the fracture and remove the callus; the callus was left to hold the fragments together. His method was to take a strong and usually large bone-graft—sometimes two—most often from the tibia, and apply it across the fracture line. He used no screws to anchor these grafts. The intermediary callus was curetted out in some cases, but the results were the same as when it was left in. The fragments were usually immobilized for two or three months. The graft became united to the fragments on either side of the fracture line. The operation was very short and simple; little blood was lost, and the principle of impaction, which Prof. Danis had emphasized, was exercised by the muscles. The muscles helped to hold graft and fragments together, and the stimulus of osteogenesis was obtained from muscle pull. He had operated on 89 such cases, with primary healing in 85. There was non-union in one case of infection, with loss of the bone-graft; in one case there was a congenital pseudo-arthritis; and in two cases he had failed to place the graft properly; it was too much on one side, and there was failure of union on the short side. All except the congenital pseudo-arthritis were corrected by re-operation. Dr. R. Demel (Vienna) described the treatment of gunshot fractures with false joint by Kirschner's splintering method; Dr. A. Westerborn (Gothenburg) spoke of the advantages of the medullary nail in fractures of the femur, and many other speakers described variations of technique.

#### Heparin in Surgery

On Thursday morning the high-light was a discussion on recent advances in surgery due to heparin. It was opened by

Dr. Clarence Crafoord (Stockholm), who declared that heparin had opened new possibilities in experimental surgery. He himself had worked for many years at the possibility of combating post-operative thrombosis but without much success until, in 1935, heparin became obtainable commercially in pure form and in sufficiently large quantities for prophylactic use. Between 1935 and 1940 two Swedish gynaecologists and he had heparinized approximately 800 patients post-operatively. In a large proportion of these the operation performed was hysterectomy. In the pre-heparin days there would have been a considerable number of cases of thrombosis in such a series, but actually there were almost no complications. Later similarly successful results were reported with dicoumarol. In Sweden the risk of post-operative embolism had now practically disappeared. He gave some figures from the Mariestad Hospital concerning cases of deep venous thrombosis. In a series of 264 cases untreated by heparin fatal pulmonary embolism developed in 47, or 18%. In a further series of 221 cases treated by heparin alone only 3 developed fatal pulmonary embolism, or 1.3%. In another series, out of 543 cases of thrombosis or pulmonary infarction submitted to conservative treatment, there were 88 deaths (16%), whereas out of 769 cases treated by heparin there were 3 deaths, and out of 131 cases treated by dicoumarol there was 1 death, a total death rate of 0.45%. The method employed was to give intravenous injections to a total of about 250 or 300 mg. a day, divided into four administrations at four-hour intervals. After three or four days the dose was reduced. The practice in Sweden now was to give heparin in all cases in which there was the slightest suspicion that a thrombotic complication might arise. In blood transfusion it was the routine procedure for heparin to be injected intravenously into the donor. Intravenous heparinization was also used in cases of polycythaemia where it was necessary to perform venesection.

Prof. W. E. Gallie described the work which Gordon Murray, C. H. Best, and others had been doing in Toronto on this subject. He said there was no doubt that heparin did control the spread of thrombosis and brought about a rapid amelioration of symptoms. By holding the spreading in check it greatly reduced the risk of pulmonary embolism. Even in cases where a non-fatal embolism had previously occurred and there was reason to expect further embolisms it was rare to find them occurring if heparin had been used. He also mentioned its value in the field of arterial surgery. After complete excavation of the thrombus and local and general heparinization of the patient the wound in the arterial wall would heal well and there would be no complications. Nevertheless, in spite of the simplicity of most of these operations, physicians were loath to transfer the cases to surgery; they were inclined to try the so-called conservative treatment until it was evident that severe changes were taking place. This was a foolish attitude, because it took away all possibility of a successful ambolectomy. If he himself had an embolus in one of his major peripheral arteries he would want a competent surgeon to remove it at the earliest possible moment and would trust to heparin to keep the vessel clear.

Dr. G. Bauer (Mariestad, Sweden) said that at his hospital heparin had been used for the past seven years, and during that time, with over 1,000 operations, not a single death had occurred from post-operative embolism. Successful heparin treatment depended largely on two factors: the possibility of arresting instantaneously the progress of the thrombotic process, and the making of an early diagnosis. With the use of heparin there would be no more of these fatal emboli coming "out of the blue" and an end also of the post-thrombotic invalidism. High venous ligation had been advocated, but it seemed to him that in any case in which either prophylactically or therapeutically high ligation was indicated heparin treatment might just as well be used instead, probably with much less inconvenience to the patient.

#### Mayo Clinic Experience of Anticoagulants

Dr. Waltman Walters (Rochester, Minn.) said that the results at the Mayo Clinic corroborated those of Stockholm and Toronto, though the series of patients who had been treated with heparin was too small to be of great statistical value. The use of heparin as an anticoagulant had been largely superseded by the synthetic chemical dicoumarol. The chief advantage of

heparin as an anticoagulant was that it was effective almost immediately after administration had begun; its disadvantage was time-consuming administration. The advantage of dicoumarol was its ease in administration; its disadvantage was the delay in its action after treatment had been started. The injection of both these drugs required careful supervision in order to be certain that an adequate but not excessive effect was obtained. At present dicoumarol alone was used for prophylactic effect in a patient who had had no previous thrombosis or embolism, but in a patient who had had this history heparin was used at the beginning concurrently with dicoumarol. In a few cases where, owing to renal or hepatic insufficiency, dicoumarol was contraindicated, heparin alone was used. Dicoumarol alone, or with heparin at the beginning of anticoagulation therapy, had been used with more than 2,000 post-operative patients, and the incidence of venous thrombosis and of fatal pulmonary embolism had fallen markedly below the level expected on the basis of previous statistics of cases treated without these agents. In 352 cases in which the clinical diagnosis of post-operative venous thrombosis had been made, and in which the incidence of fatal embolism on the basis of previous statistics was expected to be 5.7%, no case of fatal embolism developed. There seemed to be adequate statistical evidence that post-operative venous thrombosis—and therefore pulmonary embolism—could be prevented by heparin and dicoumarol. He agreed that ligation of the femoral vein as a prophylactic measure was seldom indicated.

The opinion of a Swiss surgeon, Dr. A. Jentzer (Geneva), was that heparin was less favourable in its results than the Scandinavian workers claimed. Prof. Dos Santos (Lisbon) had seen accidents, two of them fatal, with heparin in operation cases. Dr. Sandblom (Stockholm) mentioned 25 cases of bronchopneumonia in which the sulphonamides had not succeeded in lowering the temperature, but the temperature had come down after the administration of heparin, probably due to a direct effect on the fibrin deposits in the tissues and small vessels. In replying to the discussion Dr. Crafoord suggested that the reason for the difference between the Swiss and the Swedish experience might be that the Swiss had been using heparin in a less pure form. He pointed out a difference in technique between the Stockholm and the Toronto workers. The former used repeated injections of heparin at four-hour intervals; the latter used continuous intravenous administration.

It had been announced that a discussion on the surgical treatment of burns would be opened on Thursday morning by an unnamed Russian surgeon, but no Russian surgeon answered to the call, and the subject was briefly introduced by Dr. Merle d'Aubigné (Paris). An Argentine surgeon, Dr. Zeno, showed a cinematograph film of the treatment of several cases of superficial burns in which he relied entirely on immobilization in plaster-of-Paris, with a small window for observation, placed directly on the burnt surface without any dressing at all.

#### Skin-grafting

On Friday morning there was a brief discussion on the role of vasodilatation in arterial disease, which, save for a few remarks by an Irish surgeon, was entirely confined to French speakers. This was followed by a lecture by Prof. T. Pomfret Kilner (Oxford) on the repair of skin defects by flaps and free skin-grafts. Prof. Kilner gave a pictorial review of the technique and results of skin-grafting, describing in turn the Thiersch, Wolfe, Reverdin, and other methods and showing how one method was to be preferred to the others in particular cases. He added that he found it impossible to overcome the temptation to interpret rather widely the title given him, and to include in his demonstration records of cases of more purely plastic surgery interest in which grafts and flaps had been employed. He felt less apologetic about doing so because the President of the Congress (Dr. Leopold Mayer) in his opening address (reported in our issue of Sept. 20, p. 466), in reviewing the progress of surgery during the past fifty years, had failed to make any reference to the developments in this specialty.

Prof. Kilner said he felt strongly that general surgeons should always be prepared to cover any surface defect which they had produced, and that they should have at least a working knowledge of why, when, and how skin-grafting should be carried out. It must be left, of course, to their good sense and judg-

ment as to when it would be in the patient's interest to call in the assistance of a specially experienced colleague. General surgeons, too, should feel themselves quite ready to carry out radical destructive procedures, like those required in dealing with malignant disease, unfettered by the fear of producing permanent disfigurement, and confident that they or their plastic surgery colleagues could make good the defects they had produced. Only in that way could these extreme contractures and deformities be avoided. When radical amputation of the breast called for the removal of large areas of so-called "dangerous" skin there was, to his mind, a clear indication for the immediate application of a free skin-graft. Finally, the time for recovery of war wounds of a superficial character could be reduced by many weeks or even months if free skin-grafting was carried out at the first possible moment. In such cases penicillin had helped to make early skin-grafting both safe and practicable.

#### Close of Congress

The London meeting, which had included five scientific sessions, closed on Saturday. Prof. G. Grey Turner led the delegates and members on a pilgrimage of homage to places in London associated with John Hunter and Joseph Lister. The first place visited was the site of Hunter's famous house in Leicester Square. Then the pilgrims went to St. Martin-in-the-Fields, where he was originally buried. He rested there for more than sixty years, until his remains, having been identified by F. T. Buckland, were removed at the cost of the Royal College of Surgeons to Westminster Abbey. The Abbey was then visited, and after this the Royal College, where the marble statue of Hunter by Henry Weekes, R.A., which had been bricked up during the war and so preserved from the effects of the bombing, was inspected. Here also was seen the Oulless portrait of Lister, as well as various pictures and instruments having Listerian associations. Lister's house—12, Park Crescent—with his statue in Portland Place near by, were next visited, and finally the party returned to University College, where Lister started his professional studies and where, exactly 100 years ago, he took his B.A.

At a General Assembly of the International Society, held at University College, Prof. Grey Turner was elected the next President of the Congress, and the date and place of the Congress were provisionally fixed for October, 1949, at New Orleans.

#### DINNER AT THE R.C.S.

The President and Council of the Royal College of Surgeons of England entertained to dinner in the College on Tuesday, Sept. 16, representatives of most of the nations taking part in the XIIth Congress of the International Society of Surgery. The College had already given a reception on Sunday, Sept. 14.

Sir Alfred Webb-Johnson welcomed the guests and said that he regarded the Congress as a means of improving understanding between countries. Surgery was still an art, and an art to which a long apprenticeship must be served. He envisaged a day when the College would be regarded as an active headquarters of British surgery with accommodation of every kind for post-graduate teaching in surgery and for experimental and clinical research. Students might then in their early years have an opportunity of contact with the leaders of the profession, a contact which he thought would prove inspiring. He concluded by proposing the health of the President of the International Society of Surgery, Dr. Verhoogen, and of the President of the Congress, Dr. Leopold Mayer, of Brussels.

Dr. Verhoogen said that the Society was forty-five years old, and he paid a graceful tribute to the contributions made by British surgeons in the post-Listerian epoch. Dr. Mayer also replied.

Prof. René Leriche ended a characteristic speech by saying how glad he was to see present his "young" colleague, Prof. Rudolf Matas. The President of the American College of Surgeons, Dr. Arthur W. Allen, said how impressed he had been by a tour of the College and by the outline which had been given him of future plans.

Sir Henry Dale spoke on the interchange of ideas and practice between surgery and experimental science. He felt that each had something to offer the other, and he instanced the

work of Prof. Blalock, whose surgical advances were firmly based on experimental work. He welcomed the idea of a collegiate centre for graduates in surgery at the Royal College.

Prof. Alfred Blalock disagreed mildly with the "general trend of the discussion." A man who had "what it takes" did not need "collegiate residence or any kind of spoon-feeding." He recalled how he had worked in the physiological laboratories at Cambridge for some months in 1928, and from his own experience then and since he felt that it was not necessary to live too closely with great men. It was perhaps better to admire from afar as he had admired, among many others, Sir Henry Dale and Charles Best.

Mr. Evarts Graham, Professor of Surgery at the University of Washington, said that in the United States the art of surgery was being overemphasized and the science of surgery was being neglected. Surgery must be based on pathology, in line with the teachings of John Hunter and Joseph Lister, and experimental surgery must still provide the basis for any real advance in surgical science. The work of Sir Alexander Fleming and his colleagues had already brought about great changes in surgery. For the past two years he had not seen a case of post-pneumonic empyema, but where one surgical problem disappeared it seemed that another arose. With the disappearance of such cases of empyema there had been an increase in cases of atelectasis of the right middle lobe following pneumonia treated apparently successfully with penicillin.

At a late hour Sir Alfred Webb-Johnson summed up the views which had been put forward by different speakers, and brought a memorable evening to a close.

#### Receptions

On Wednesday evening there were two receptions for the delegates to the Congress. The President and Council of the B.M.A. had some 300 guests, who were received early in the evening by Sir Lionel and Lady Whitby. Later, many of the delegates went on to the Royal Society of Medicine, where they were welcomed by Sir Gordon and Lady Gordon-Taylor. Another reception was arranged for Thursday by the Royal College of Surgeons, and on Friday receptions were given by His Majesty's Government at Lancaster House, and by Sir Hugh and Lady Lett at the Hall of the Society of Apothecaries.

The Surgical Instrument Manufacturers' Association entertained some of the delegates to the Congress at a dinner at the Savoy Hotel on Friday. The chairman, Mr. H. Guy Radcliffe Drew, welcomed the many guests, and Prof. René Leriche, Sir Max Page, and Prof. J. de Fourmestreaux replied. Dr. L. Dejardin proposed "The Ladies," and there were brief replies from Mrs. Arthur W. Allen, Mrs. H. W. S. Wright, and Miss Jane Drew. The final event of the Congress was a dinner, of which Viscount Kemsley was the host, with Dr. Leopold Mayer presiding, and Prof. Grey Turner, Sir Alfred Webb-Johnson, and Dr. René Leriche among the speakers.

## AMERICAN SURGEONS HONOURED

### Presentations at Royal College of Surgeons

Five American surgeons who had been visiting this country for the International Congress were admitted Honorary Fellows of the Royal College of Surgeons, another was presented with the Honorary Medal of the College, and another with the Lister Medal, at a special ceremony at Lincoln's Inn Fields on Sept. 22. Sir Alfred Webb-Johnson, P.R.C.S., who presided, said that the records of those whom it was proposed to honour were a reminder of the many great achievements of the clinics and laboratories of the United States and Canada.

The first recipient of the Honorary Fellowship, Dr. Arthur W. Allen, president of the American College of Surgeons, was introduced by Sir Heneage Ogilvie, who said that Dr. Allen was head of one of the two surgical services and lecturer in surgery at Harvard. He had made contributions of lasting importance to gastric surgery and had been a great friend to all British surgeons who visited Boston. Dr. Allen accepted the honour not merely as a personal one but as one done to the institution of which he was the temporary head. Dr. Irvin Abell, of Kentucky, was introduced by Mr. L. E. C. Norbury as a past president of the American College and a member of

the Board of Regents. Dr. Frank Howard Lahey, director of the Lahey Clinic, Boston, was introduced by Sir Cecil Wakeley, with the remark that he was president of the American Medical Association in 1941 and consulting surgeon to the U.S. Navy in the Second World War, serving most of the time in the Pacific theatre. Dr. Dallas B. Phemister, president-elect of the Royal College, was introduced by Sir Hugh Cairns. His work on bone necrosis, said Sir Hugh Cairns, was classical in its comprehensiveness and its use of the experimental and clinicopathological approach. He was professor of surgery at the University of Chicago. The last recipient was Dr. Alfred Blalock, professor of surgery at Johns Hopkins University, Baltimore, and in the words of Prof. H. W. Rodgers, who introduced him, the master vascular surgeon, whose efforts in this field had saved many young lives.

Dr. W. E. Gallie, past president of the American College, was introduced by Sir Max Page for the Honorary Medal. Sir Max Page said that the Honorary Medal, which was established in 1802, had been awarded only on some twenty occasions. Among its recipients were Paget and Lister. For twenty years or more as professor of surgery in Toronto Dr. Gallie had put his stamp on the Canadian surgery of our generation. Dr. Gallie said that he had come to England nearly forty years ago to win his scholarship, and fifteen years later as Hunterian professor. He took this award as meaning that he had to some extent succeeded in upholding the traditions of the College in his distant country. Dr. Evarts Ambrose Graham, a former president of the American College, was introduced by Mr. H. S. Souttar for the Lister Medal. Mr. Souttar said that Dr. Graham had been professor of surgery in Washington for twenty-eight years. He was at one time temporary professor of surgery at St. Bartholomew's. The President said that this medal was presented in the name not only of the College but of the Universities of Edinburgh and Glasgow and the Royal College of Surgeons in Ireland.

The American visitors then took the dais and presented as a gift from the American College a beautiful oak table and lectern, with symbolic decoration and a suitable inscription. Dr. Irvin Abell, recounting the circumstances of the gift, said that the American College had long desired to express the friendship which bound the two institutions together. He recalled the visits of many famous surgeons to the States—Sir Rickman Godlee in 1913, Sir Berkeley Moynihan, as he then was, in 1917, when he delivered a stirring address on the war, and again in 1920, when he made a memorial oration, and among others since then Sir Anthony Bowlby, Prof. G. Grey Turner, Sir William de Courcy Wheeler, Sir W. Arbuthnot Lane, Mr. Arthur Burgess, Sir John Bland-Sutton, Sir Alfred Ballance, Sir Heneage Ogilvie, and Sir Gordon Gordon-Taylor. The President of the College, Dr. Allen, having made the presentation "as a token of high esteem and undying friendship," Sir Alfred Webb-Johnson received it with appropriate expressions of pleasure and gratitude. He mentioned that the final polishing and the addition of certain details of ornament had been left in British hands, and the workmen in charge had been lost in admiration of the quality of the timber and the craft put into the construction. He said that the table and lectern would be not merely a part of the furnishing of the College but a part of its history.

The first lecture was then delivered from the lectern by Dr. Allen, the president of the American College. This was the Moynihan lecture, and the subject was duodenal ulcer. A report will appear in our next issue.

## AMERICAN COLLEGE OF SURGEONS

### CLINICAL CONGRESS

[FROM A CORRESPONDENT]

Throughout the week Sept. 8-12 the American College of Surgeons has been holding its thirty-third Annual Clinical Congress at the Waldorf-Astoria Hotel, when over 5,200 surgeons attended. On general lines the arrangements for the congress resembled those of the A.M.A. Centenary Meeting described in an earlier number of this *Journal* (June 28, p. 931). The scientific exhibits and clinical and surgical demonstrations were staged in near-by institutions. As an indication of

America's numerous centres of clinical research, it was interesting to see that, although it is only three months since the A.M.A. meeting, a large proportion of these exhibits were on original and unpublished work.

As was to be expected, many of the papers in the gastric surgery forum were on various aspects of vagotomy, both in the human subject and in experimental animals. In the cardiovascular surgical forum there were several papers on portacaval anastomosis, one on a new operation for left coronary thrombosis and sclerosis, and another on experimental methods of aortic valvulotomy. In other sections there were papers on the evaluation of streptomycin in intestinal strangulation and as a pre-operative medicament for abdominal surgery, and studies on its influence on post-operative healing of the bowel. The role of isotopes in biological research was also discussed, and economic details and an account of the liaison between the research worker and the physicist were given.

The twenty-sixth Annual Hospital Standardization Conference was held in conjunction with the surgical conference. Papers and discussions ranged from problems in hospital management and finance, through technical aspects of labour and staffing, to the relative value of various publicity media in attracting public interest and support. Of particular interest was a speech by Prof. Charles B. Puestow, Deputy Chief of Surgery at the Veterans Administration Hospital at Hines. He outlined details of the reorganization programme brought about by General Omar Bradley and Drs. Paul R. Hawley and Paul B. Magnuson, as a result of which the care of ex-G.I.s is brought directly under the supervision of the nation's great medical schools. The programme is not yet completed, but 56 schools are at present supervising the work in 62 V.A. hospitals. The scheme covers the war casualties of thirteen million men and is expected to save \$2,000,000,000 a year. The upkeep of this enormous service is of course borne by the State. It has received a warm reception from a profession which is, by and large, vociferously opposed to State medicine.

In one respect at least the American College of Surgeons can claim to have made history at this convention—in the use of television to demonstrate surgical operations. It may be recalled that this method was used at the Johns Hopkins University earlier in the year when a surgical demonstration was televised to another room in the same building. This week a further step was made. Seven major operations performed on the tenth floor of the New York Hospital were successfully projected on television screens on the fourth floor of the Waldorf-Astoria Hotel. A narrow "line-of-sight" beam was used that could not be picked up by other receiving aerials, thus keeping the broadcast private. This development seems to be an important step in the advancement of surgical teaching. The usual complaint by anyone who has been televised of the extreme heat generated by the illuminators. Good stage lighting and a super-sensitive camera make this unnecessary; and, as the lens can be centred directly above the field of operation, the screen gives a view of structures undreamed of by those accustomed to seeing little but the back of the surgeon's head. The viewing was limited to seven small screens, but experiments are being made in the use of a large cinema-sized screen more suitable for class teaching. The estimated cost of this televising, which lasted about 16 hours, is \$5,000, borne in this instance by commercial enterprise.

The convocation ceremony ended the congress on Sept. 12, when 762 new Fellows were admitted into the College and honorary fellowships were conferred on Lieut.-General Robert K. S. Lim, the distinguished Chinese physiologist, and on Dr. Benedicto Montenegro, of Brazil, the author of many communications on gastro-intestinal surgery. Dr. Arthur W. Allen, of Boston, presided at the ceremony, the initiates being presented by the retiring president, Dr. Irvin Abell, of Louisville. In delivering the fellowship address, Prof. Ivy, of the University of Illinois, advocated the establishment of a Federal loan fund for meritorious students who wished to embark upon a medical career. He stressed the value of a loan as opposed to a gift in maintaining the student's proper pride, and gave it as his opinion, based on teaching experience in two world wars, that the institution of Government grants to medical students was followed by a falling off in the standard of work. This, he felt, would not be the case if the money was merely lent and had to be repaid.

## Correspondence

### Planning and World Population

SIR,—Your recent leading article on "Planning and World Population" (Aug. 9, p. 214) might do real harm by its implication that the economic problems of our African Colonies can only be solved by a decrease, or at least a restraint of increase, of the population. Your final conclusion that unless the birth rate falls in relation to the death rate and the population problem is solved much talk about colonial development and welfare is "whistling in the wind" is so drastic that the grounds on which you make it deserve some analysis.

The doctrine which Malthus propounded in his first edition, and later elaborated, remains as true as when it first appeared. Human populations have a tendency to increase which is far greater than the usual increase in the supportive capacity of land, resulting in a constantly operating check on population from difficulty of subsistence, or the striking of a balance between the numbers of the population and the resources available to support it. The balance is normally held by two types of checks on the population—preventive ones limiting the numbers of births, and positive ones increasing the numbers of deaths through misery, disease, and famine.

At the time when Malthus wrote England was an agricultural country, and the balance was kept with a population density of about 150 to the square mile. Since then an increase in its resources and supportive capacity as a result of industrialization has made possible an increase to 727 people to the square mile, though the next few years will show whether or not the recent loss of many of these resources can be made up to enable this density to be maintained. In India the condition is much the same as that in England at the time Malthus wrote. There is an overall density of about 200 people to the square mile, subsisting on what is on the whole a reasonable utilization of the country's resources. After a long period of practical stasis the population started to increase about 1911 following the reduction of the check of famine, not because the total available foodstuffs increased but because improved transport and organization facilitated the distribution of crops, so that local deficiencies could be matched by surpluses from elsewhere. The limit of increase made possible in this way has probably now been reached, and soon the balance must again be struck either by preventive checks on births such as you advocate or by increase of deaths due to the recurrence of famines and less dramatic food shortages. The resources of the country are at the present time used in a relatively efficient manner, and only some major change in the principles of agriculture could increase them sufficiently to enable India to carry a much greater population.

The condition is much the same in several other tropical countries, notably Java, Mauritius, and Jamaica, with densities of 960, 590, and 278 to the square mile, fully utilizing all the readily available resources of the land. In most African countries, however, the position is very different. The general picture is one of gross underpopulation due to a failure to utilize what should be readily available resources, and to ignorance of the elements of husbandry. It is true that a balance between population and supportive capacity of the land has been reached, but the latter is so clearly open to improvement that advocacy of population restriction is at least still unnecessary, and its practice would result in failure to develop central Africa into an important economic unit.

The density of population in our Colonies on the mainland of Africa varies from 64 to the square mile in Sierra Leone to 1 in Bechuanaland. A representative picture may be drawn from the East and South-east African group of Uganda, Kenya, Tanganyika, Nyasaland, and Northern and Southern Rhodesia with densities of 41, 17, 15, 36, 5, and 11 to the square mile. These countries include mountainous, arid, and infertile lands, but not more so than India. Almost throughout them the rainfall is adequate for the growth of crops and at least as well distributed as in the monsoon countries of the East. Dixey (1926), Gillman (1936), Baker (1937), and Baker and White (1947) have studied their population problems from the ecological point of view. The last authors summarize the position for the whole of south-east central Africa by saying that the population is undoubtedly far below its optimum level. Gillman points to half a million square miles of land in Tanganyika, 62% of the whole country, which is unpopulated largely as a result of the absence of perennial supplies of domestic water as a result of the absence of simple methods, though simple methods could readily be tapped by primitive tools, which are of great extent in Nyasaland. Dixey points to similar areas of great extent in Nyasaland where domestic water is readily available within a few feet of the ground surface though its absence from the surface itself has prevented the development of the country. Similar areas in India such as the Punjab were colonized thousands of years ago by the universal development of wells and water conservation systems.

## *Vitamin Therapy* *- its uses and limitations*

### THE NEEDS OF PREGNANCY

While the need for dietary supplementation is sometimes questioned, the only reliable way of assessing its value is by statistical examination of the results of large scale controlled clinical trials. An investigation involving records of over 5,000 pregnant women attending 10 London hospitals showed that the incidence of toxæmia in primigravidae given vitamin and mineral supplements was significantly less than among untreated controls.

Pregnavite was designed specifically to make good the dietary deficiencies revealed by the early surveys and has proved most useful in obstetric practice.

### PREGNAVITE

**A single supplement for safer pregnancy**

The recommended daily dose provides:

vitamin A 4,000 i.u.	vitamin E 1 mg.	iodine	} not less than 10 p.p.m. each
vitamin D 300 i.u.	nicotinamide 25 mg.	manganese	
vitamin B <sub>1</sub> 0.6 mg.	calcium 160 mg.	copper	
vitamin C 20 mg.	iron 68 mg.

# "FELLOWS" TRADE MARK COMPOUND SYRUP OF HYPOPHOSPHITES

Formula: Each fluid drachm contains:

Manganese Hypophosphite	Gr. 1/8	Iron	Gr. 1/8
Potassium Hypophosphite	Gr. 1/8	Quinine	Gr. 1/20
Sodium Hypophosphite	Gr. 1/8	Strychnine	Gr. 1/64
Calcium Hypophosphite	Gr. 1/3		

A long-tried and most valuable compound containing Strychnine, Quinine, and several important Mineral Salts.

Produces a bitter and therefore tonic effect upon the alimentary canal; improves tone and nutrition of muscle;

and provides limited respiratory and vasomotor stimulation.

"FELLOWS" is a reliable compound, manufactured under the strictest supervision, and with a consistency of quality that only the greatest care in manufacture can ensure.

## invented by a Doctor . . .

**TAMPAX**, first introduced in 1934, was the direct adaptation by a practising Doctor of the principle of the surgical tampon to the absorption of the menstrual flow. As such, it received the approval of the medical profession, not only for its alleviation of mental stress and physical discomfort but for its hygiene and absolute safety—ensured by the Tampax patent stitching process which positively prevents disintegration. Today that approval is world-wide. Tampax is recognised as both the pioneer and the best form of sanitary protection worn internally. If you are not receiving copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to: Medical Inquiries, Tampax Ltd., 110 Jermyn St., London, S.W.1.

*Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hygienic aperture would cause difficulty in insertion and withdrawal.*

Sanitary Protection

**TAMPAX**

Worn Internally

has won the approval of Doctors everywhere

TAMPAX LTD., BELVUE ROAD, NORTHOLT, MIDDLESEX

## ‘TRILENE’ ANALGESIA IN OBSTETRICS

‘Trilene’ produces an effective and constant plane of analgesia which can be easily maintained without loss of consciousness.

In midwifery its auto-administration by means of various types of inhaler has proved highly satisfactory for relieving labour pains; the analgesia produced is adequate and safe for mother and child.

There are no contra-indications, untoward effects are rare and recovery is rapid. The method is simple and convenient and secures the ready co-operation of the patient.

‘Trilene’ is issued in containers of 8 oz. and 1 lb.

Literature on request.

ALDERLEY EDGE, MANCHESTER

Ph. 196n

Without submitting any ready solution of Africa's problems I suggest that it should be borne in mind that the population problem is one of balance, and that the economy of grossly underdeveloped countries can be improved more readily and more to the general advantage of the world by an increase in the supportive capacity of the land than by a restriction of population, though ultimately that must come. Colonial development is not "whistling in the wind" but the essential background of human welfare, which should be at least as much the concern of your readers as the policy of despair you advocate. The ignorant and poverty-stricken peasant is admittedly an inadequate foundation for an enlightened state of society, or for the production of goods to be exchanged with industrial countries. The remedy may lie in the cure of his ignorance and poverty rather than in the restriction of his numbers.—I am, etc.,

London, W.C.1.

G. MACDONALD.

## Poliomyelitis

SIR.—Three out of a total number of 33 cases of acute anterior poliomyelitis under my care have developed symptoms which were regarded as due to paralytic ileus. The three cases were severe, with widespread paralyses, and the symptoms of bowel paralysis appeared three days after the first onset of paralyses in the voluntary muscles.

In one of the cases there was no abdominal pain, but in the other two complaint was made of abdominal aching. In all the cases the abdomen began to swell progressively; the swelling was tympanitic and there was absolute constipation. No flatus was passed. In one of the cases, a woman of 50, the swelling rapidly became enormous, but she complained of no feeling of discomfort. The main danger of the abdominal distension is embarrassment to the heart and respirations in a patient with some degree of diaphragmatic paralysis.

Treatment consisted of 1 ml. of "prostigmin" followed four hours later by a further 1 ml. and a turpentine enema. This resulted in slight colicky pain, followed by the passage of flatus and faeces, with disappearance of the abdominal distension. In children the dose of prostigmin used was 0.5 ml. After the subsidence of the abdominal swelling constipation again followed in one of the cases, but prostigmin 0.5 ml. daily relieved this.

The treatment I have used in all cases with paralysis has been: vitamin B<sub>1</sub> tablets, 1 t.d.s., together with strychnine, 1/32 gr. (2 mg.) b.i.d. in the case of an adult, and 1/60 gr. (1 mg.) in the case of a child.—I am, etc.,

JOHN MILLS.

Newport, Isle of Wight.

SIR.—Though there is no specific treatment as yet for this disease, for some six or seven years I have treated the comparatively few patients I have seen in the very early stages of the attack by intramuscular injections of their own cerebrospinal fluid, 5 ml. given daily or on alternate days according to the severity of the illness, three or four injections being the usual amount. As many patients recover completely without any treatment, and as the general tendency is towards at least partial recovery, it is impossible to assess the value of this or any other form of treatment. In a number of cases it appeared to be of some value towards arresting the progress of the attack.

Two patients were treated by intramuscular injections of blood taken from people who had had the disease; some benefit appeared to result. Is it possible that convalescent serum (such as is given to abort or attenuate an attack of measles) might be of use? Obviously this form of prophylactic treatment could only have a very limited application.—I am, etc.,

Purbrook, Hants.

GEOFFREY EDEN.

SIR.—In Prof. H. J. Seddon's recent paper on the early treatment of poliomyelitis (Aug. 30, p. 319) it is very depressing to read that no really early treatment is possible. During the past few years letters have appeared in the *British Medical Journal* advocating early treatment for herpes zoster—another virus disease which attacks the central nervous system—publishing records of cases showing successful results. In my own

practice treatment of herpes zoster by injections of vitamin B<sub>1</sub>, 25 mg., and liver extract and "contramine," 0.125 g., repeated if necessary, appears to have yielded satisfactory results. After a personal attack I can vouch for the fact that these injections are only uncomfortable.

In the present epidemic many cases will probably be diagnosed in the pre-paralytic stage, and it would appear possible that this line of treatment may be worthy of a trial, particularly when there is no alternative. Whether the present widespread sub-optimum intake of vitamin B<sub>1</sub> is a factor in the spread of poliomyelitis is another question which might be asked of those qualified to give an authoritative answer—I am, etc.,

St. Faiths, Norfolk.

J. N. GALE.

SIR.—It was with great interest that I read the note by Dr. J. N. McIntosh (Gloucester) (Sept. 6, p. 398) on the treatment of poliomyelitis by complete rest in bed, sulphonamide therapy, and isolation, and I would like to emphasize the necessity of giving the sulphonamides in massive doses in the early stage of the illness, especially in the more severe type of case, if subsequent paralysis is to be avoided. In such cases the drug should be given intravenously, due regard being paid to the fluid intake, alkalis, and the cytology of the blood. Initially I give for a young adult with a severe attack 4 g. of a soluble preparation of sulphonamide by the intravenous route, followed by 3 g. at intervals of twelve hours for two or three days.

In a series of over twenty cases of the severe type treated on these lines there has been either no paralysis supervening, or, where treatment was delayed and paralysis had already commenced, there has been no further extension of it.—I am, etc.,

Harrogate.

SINCLAIR MILLER.

## Early Diagnosis of Tuberculous Meningitis

SIR.—Now that centres have been established for the treatment of miliary tuberculosis and tuberculous meningitis by streptomycin, a readjustment is necessary in our ideas about these forms of tuberculosis. Previously a diagnosis of tuberculous meningitis has been a sentence of death, only to be accepted when there is no longer any possibility of error. The possibility of cure has altered that, and early diagnosis has become a matter of particular importance, for it is not to be expected that patients will recover completely once damage to the brain has occurred. Therefore, it is necessary to study the early diagnosis of tuberculous meningitis. As the result of more than twenty years' experience in the treatment of children with tuberculosis I have formed the following opinions.

In many cases there is a prodromal period during which the disease is establishing itself and during which the signs and symptoms are very variable. The chief aids to diagnosis are clinical and neurological examination, examination of the cerebrospinal fluid, and radiography of the lungs. Any one of these may precede the others in providing evidence on which to base the diagnosis. Gross evidence, either clinical, laboratory, or radiological, means that the disease is becoming established, and brain damage may be already present. Fever of unknown origin and persistent headache in a child, especially one who is a tuberculosis contact or has some overt tuberculous disease, merit lumbar puncture and chest radiography. Even when neurological signs are absent, and when the cerebrospinal fluid is normal except possibly for a slight rise in the lymphocyte count, early miliary tuberculosis may be seen in the lungs; or, if the chest x-ray examination and neurological signs are negative, the cells in the cerebrospinal fluid may be definitely increased.

Early neurological signs may be equivocal and it is unwise to delay until they become well established. If there is present a combination of fever of unknown origin, persistent headache, and some definite evidence, however slight, from any of the triad, clinical, laboratory, or radiological, then streptomycin should be started. A specimen of the cerebrospinal fluid, injected before treatment into a guinea-pig, will probably reveal later whether the patient has been cured of tuberculous meningitis or an error in diagnosis has been made. In either case the patient's life will have been safeguarded to the best of the doctor's ability.—I am, etc.,

Braintree, Essex.

M. C. WILKINSON.

### Complete Prostatectomy

SIR,—The case described by Mr. H. S. Souttar (June 28, p. 917) of complete removal of the prostate confirms some observations made when removing the entire prostate, seminal vesicles, and base of the bladder in a case of carcinoma of the prostate.

#### CASE HISTORY

The patient, an Indian peasant of some seventy years, was thought to have an adenomatous prostate, with retention of urine. His general condition was fair, but his blood urea was 120 mg. %. A suprapubic cystostomy was performed. Five weeks later a Freyer type prostatectomy was attempted, but it was soon evident that one was dealing with a carcinoma of the prostate which was infiltrating into the bladder wall.

As one side of the prostate was already partly freed, it was decided to complete the dissection with curved scissors. The tumour was gripped with Lane's forceps and pulled upwards into the bladder, and, keeping as far as possible outside the area of induration, it was snipped away. Eventually the prostate was found to be attached only by the urethra, which could be stretched to some 3 cm. easily. It was divided about 1 cm. from the prostate. The remainder immediately retracted away. Meanwhile a blood transfusion had been commenced.

The specimen was seen to consist of the base of the bladder, both seminal vesicles, and the whole prostate, which was the seat of a carcinoma invading the surrounding tissue. The lower ends of the ureters were not identified. 1 cm. of urethra was present. An examining finger felt an alarming gap in the base of the bladder, which was oozing freely. No attempt was made to suture the edges of this gap to the urethra. A large rubber catheter was passed across the gap into the bladder, the oozing was controlled by packing, and the bladder and abdomen were closed with drainage.

After some initial shock the patient made a rapid recovery. He was discharged with no apparent abnormality six weeks after operation. He had complete control of his urine. X-ray investigations of his pelvic bones showed no secondary deposits. Nevertheless stilboestrol therapy was prescribed. Castration was refused. Unfortunately a follow-up was not possible.

This case appears to confirm the anatomical findings concerning the urethra as described by Mr. Souttar, but it would seem that suture of the urethra to the neck of the bladder and the base of the bladder to the triangular ligament are not necessary. Indeed, in the transvesical approach used in this case it would hardly have been possible.—I am, etc.,

Ajmer, India.

G. P. CHARLEWOOD.

### Thalamic Dysfunction and its Treatment

SIR,—Dr. B. H. Kirman (Aug. 30, p. 348) taxes me with failing to "distinguish between experimentally proven fact and theories with little experimental support," apparently refusing to credit my statement that psychotic and neurotic depression can be distinguished by their specific response to E.C.T. This statement is based on a study of several hundred cases treated over a period of more than five years largely spent as a psychiatric specialist in various military hospitals for acute psychiatric cases. If this is not "experimentally proven fact" I would be extremely interested if Dr. Kirman would explain exactly what he means by this expression.

With regard to the nature of the syndrome itself, a detailed discussion of the evidence for my hypothesis was naturally beyond the scope of a short paper devoted mainly to the subject of pharmacotherapy. The subject of emotional disturbances in relation to disorders of the thalamic-hypothalamic mechanisms is fully dealt with in a number of up-to-date neuropsychiatric papers; in particular I would refer Dr. Kirman to the excellent chapter on the subject in D. T. V. Moore's book *The Nature and Treatment of Mental Disorders*, New York, 1943. In any case I fail to see why the hypothesis put forward in my paper should seem any more far-fetched or incapable of scientific proof than the bizarre concepts upheld by many present-day psycho-analytic enthusiasts.

Now, to turn from controversy to the more practical aspects of the question. No psychiatrist, I venture to think, would disagree with two of the main points in my article: first, that the symptom of anhedonia, or morbidly increased susceptibility to unpleasant sensation and affect, is a constant and almost invariable feature of neurotic patients; and, secondly, that it is one of the worst therapeutic headaches which beset both psychiatrist and general practitioner, on the last-named of

whom ultimately devolves the care of the vast majority of these unfortunates.

The psychiatrist, unlike the surgeon or physician, labours under a great handicap—namely, the lack of specific drugs for the different conditions with which he has to deal. Modern chemotherapy, with its endless variety of potent compounds, offers by far the greatest possibilities for a rational attack on the problem of therapy in mental disorders. If adequate and co-ordinated research along these lines were forthcoming, there should be no reason for psychiatry to lag behind its sister sciences in the field of chemotherapy. What does not seem to be generally realized is that more and better specific drugs for psychiatric conditions are an even more pressing need than more clinics and specialist workers. The work on which my paper was based was carried out in the hope that thereby interest in this subject would be generally stimulated. Let us therefore have discussion and criticism by all means, but let it be intelligent and constructive and directed towards a rational and practical solution of the problem.—I am, etc.,

London, S.E.6.

G. TAYLEUR STOCKINGS.

### Intravenous Infusion and Transfusion

SIR,—In his article of Aug. 30 (p. 333) Mr. Hamilton Bailey appears to continue the tradition that transfusion is a formidable procedure requiring complicated apparatus and taxing the skill of the average house-surgeon in setting one up and keeping it going. He still advocates the use of the median cubital vein, and cuts down on it as a routine.

This is an unsatisfactory vein for several reasons. (1) It is frequently tortuous and does not permit the insertion of sufficient length of needle to ensure its remaining in position. (2) It necessitates the splinting of the arm in the extremely uncomfortable position of full extension and supination. (3) If the vein is damaged by a haematoma or thrombosis it tends to block the distal veins and render them unfit for use. (4) Cutting down renders the vein useless for later transfusions and immeasurably increases the risk of sepsis, even with careful technique.

A much more satisfactory vein is the distal part of the cephalic vein, about two inches above the wrist on the radial border of the forearm. It is long and straight, and is anchored by being formed like an inverted Y by tributaries, and is nearly always as wide as the median cubital vein. Also it necessitates only light splinting of the wrist, so that the patient can move his arm into comfortable positions. Cutting down is rarely necessary unless the transfusion is required for more than 48 hours, provided the vein is well dilated before needling. This necessitates adjusting the tourniquet at least five minutes before needling, while the rest of the apparatus is being tested, and is further helped by briskly flicking the skin over the vein. Hot pads are rarely necessary.

If the needle is then inserted into the Y junction of the veins, even a beginner can hardly fail to get it in up to the hilt, and if the tubing and needle are fixed directly to the arm by strips of adhesive tape the transfusion will usually run for 24–48 hours with very little trouble. For beginners a syringe connected to the needle is useful for ensuring clear entry into the vein, but with a little practice the needle can be inserted already connected to the apparatus, entry being ascertained by free flow through the drip chamber once the tourniquet and stopcock on the tubing are opened.

This method is apparently not widely known, but was well tried as the standard method in the Army transfusions, often being set up under very difficult conditions and surviving ambulance journeys and all other vicissitudes of battle casualties far better than traditional methods.—I am, etc.,

Guildford.

CHARLES CRAWFORD.

### Foetus Cries

SIR,—On Tuesday, Sept. 2, at 11.30 a.m. at the Trowbridge Hospital I endeavoured to induce labour in a 2-para woman at the 39th week of pregnancy by means of a Drew-Smythe catheter. The head was floating. The catheter passed very easily through the cervix and punctured the membranes without use of the stilette and also without passing as far round the baby's head as I had intended. Liquor flowed at once in a steady stream without bubbles. When the stream slowed a hand was placed on the abdomen and a further ounce or so of liquor came away.

While still standing behind the patient, having just removed the catheter, I was astonished to hear the baby cry. I did not at first believe my ears, though I said it sounded like the baby

crying, Sister said and repeated, "It is the baby crying"—and it was. The mother also heard it. I got a foetal stethoscope and went round to the front of the mother to listen to the foetal heart and heard the crying again, louder than before. The baby cried a third time, but I had left the room hoping to find another doctor near, and only Sister and the patient heard it. No further intrauterine crying was heard.

More liquor drained during the afternoon. Contractions began about 6 p.m., and the baby was born at 12.10 a.m.—i.e., over 12 hours after the intrauterine crying. It cried at once and is quite well.

(It would have been possible for the Drew-Smythe to have been passed into the child's mouth.)—I am, etc.,

Trowbridge.

E. CURPHEY.

### Examining Overseas

SIR,—The recent tragic death of one of the most able members of our profession shortly after a long round of examinations overseas calls attention to an important aspect of these tours. I can speak with personal experience of several such trips and considerable experience of long-distance flights. In this particular case I met two of the examiners in Cairo on their way home. Both were tired men, and one was completely exhausted.

Those invited to undertake this work are of necessity busy men with heavy commitments at home. It is sometimes held out as an inducement that no time will be wasted and that the tour will only occupy some surprisingly short period of weeks. The tour in such circumstances is extremely trying. Oral examinations and marking of papers are crowded into a minimum of time before the examiners fly—often at awkward hours—to their next appointment, and finally start on their homeward journey tired out, usually to pass through rapid changes of climate with only a few hours' rest at night. Return home involves instant immersion in a welter of arrears and urgent engagements, and a holiday is an impossibility.

If further tragedies are to be avoided these tours should be planned to allow reasonable leisure, and a rest in some pleasant surroundings should be arranged to take place before the trip home. Electing bodies should not only provide for such rest but insist that it should be followed in spite of possible protests by examiners.—I am, etc.,

London, W.1.

HENRY TIDY.

### Housing the Infirm

SIR,—The recent B.M.A. booklet on *The Care and Treatment of the Elderly and Infirm* is so excellent that all who are interested in the welfare of old people hope that it will reach a wide public. This subject, once scarcely developed, is now being given more prominence, and it is to be desired that many more doctors should realize the interest of tackling this difficult problem, of exploring new methods and seeking for fresh solutions. There is plenty of room for creative work.

Among the list of publications consulted by the B.M.A. special committee which drew up this work my booklets are mentioned. As they are now out of print, I have given one of the few remaining copies of *Housing the Infirm* to the B.M.A. Library. I wish to point out, however, that it was written in 1937, and that if I were going to republish it to-day it would have to be amended in several important respects. There is little that I should wish to omit, but much that I might add.

Part I consists of suggestions for brightening up existing public assistance institutions, both how to improve the appearance of the rooms and how to provide a more interesting life for the inmates. Points like permission for daily visiting, the wearing of private clothing, and the provision of more occupations have now been officially recommended in the Ministry of Health Circular 49/47. The chapter on pocket money is now out of date, since Miss Irene Ward's Poor Law (Amendment) Act, 1938, allowed the authorities to give it to inmates aged 65 or more; and, after a long campaign, all of them, including the Scots, agreed to do so. Further sections could well be added in order to mention the more difficult types of patient—senile, bedridden, incontinent, and so on—as I am afraid that to readers unfamiliar with institutions the impression might be given that the author believes that the majority of inmates would be suitable for transfer to small hostels. This is not the case. Probably no more than a fifth, or at most a quarter, of the present elderly inmates in institutions could be suitably provided for in

hostels run on the freer lines of voluntary ones. All authorities should, however, be encouraged to follow the lead of those progressive counties and county boroughs which have already provided such hostels, in some cases for several years. Their experience proves what great satisfaction is given to those old people capable of enjoying a fairly active and normal way of life in the background of an ordinary large house.

Part II consists mainly of advice on how to build new institutions for the old. It is to be hoped that this will be relevant some day, as most people would like to see scrapped the worst of our old-fashioned public assistance buildings. In view of the present building crisis, however, authorities are unlikely to be able to build afresh for some years. If, therefore, I were to republish my booklet to-day I should stress the advisability of buying up or taking over ordinary fairly large houses, which do not require very much adaptation. In some ways they may even be preferable to new erections, since they were built originally as private homes and therefore do not smack of institutions.

The last chapter in the book I would now put first, since I regard it as the most important. It stresses the fact that it is the staff, far more than the building, which makes or mars the happiness of those who "go in."—I am, etc.,

London, S.W.7.

OLIVE MATTHEWS.

### British Rheumatic Association

SIR,—An association to forward the interests of sufferers from rheumatism has been formed on the lines of the well-known Diabetic Association. Mr. H. G. Wells, who was largely responsible for the founding of the Diabetic Association in 1933, prophesied that it would be followed by other associations of people with a common disability.

A letter dated House of Commons, May 19, 1947, was signed by five M.P.s representing all parties: Lady Megan Lloyd George; Col. Stoddart-Scott, and Major C. York; Dr. S. W. Jeger and Mr. Stephen Taylor. This was published in the Press. The key paragraph read as follows:

"A Rheumatic Association is visualized to organize the general welfare of sufferers on a national scale both by direct action and advice and by assisting existing institutions. There would be an executive and an advisory staff, and a monthly journal to keep sufferers, and the public generally, informed of developments in the treatment of rheumatism, of research into the disease, and of matters of public health bearing on rheumatism."

The response to this letter justified the founding of the Association. It has been constituted essentially as a lay body with lay activities; its Council must always have a non-medical majority. Apart from myself, the medical men at present serving on the Council are: Dr. Francis Bach, Dr. S. W. Jeger, M.P., Dr. C. E. Lakin, Col. Stoddart-Scott, M.P., and Dr. H. D. Wyatt. The following are among those who have consented to be titular vice-presidents: the Marchioness of Reading, Lady Megan Lloyd George, the Dean of Westminster, Sir Ian Fraser, Sir Alan Herbert, Sir Ralph Richardson, Sir Harold Tempamy, the Earl of Scarborough, Mr. Percy Rockliff, and the Rt. Hon. Tom Williams.

The British Rheumatic Association is not intended to rival any existing body. It has, in fact, the approval of the Empire Rheumatism Council, and is seeking registration as a charity trust. It has been formed primarily to help rheumatic sufferers to help themselves; but its membership is open to all who are interested in rheumatism, whether sufferers or not. The subscription has been fixed at 10s. per annum. Donations would be welcomed. The headquarters of the Association is at 118-120, Wardour Street, but written communications should be addressed to the Hon. Secretary, Mr. A. C. M. Bowen, B.A., at the clerical department, 111, Woodville Road, New Barnet, Herts.—I am, etc.,

New Barnet, Herts.

F. HERNAMAN-JOHNSON,  
Chairman of Council, B.R.A.

The Report of the London Council of Social Services for the Year 1946-7 has recently been published. Of particular interest is the expansion of the Old People's Welfare Department that it reveals. An experimental London Federation of Homes for the Aged has been set up with the object of raising the standard of homes for the aged and for providing a consultation service. The Federation is planning a conference for matrons of old people's homes. The London Council has surveyed the home help available for old people in various boroughs. Ten local committees are now providing mobile meals services and centres.

## Planning and World Population

Dr. R. AHMAD (Dagenham, Essex) writes: In your leading article of Aug. 9 (p. 214), "Planning and World Population," there are two tacit assumptions for which there is no foundation in actual experience or scientific observation—first, that so-called "contraception" is a satisfactory substitute for normal sexual intercourse; secondly, that this method has successfully solved the population problem in European industrialized communities. A stationary population cannot be considered to be a successful result if the proportion of the younger age groups continues to decrease, and if, as a result of socially unequal reduction of births, the average level of intelligence of the population goes down. Yet these are the unmistakable trends here (*British Medical Journal*, 1947, 1, 185). . . . In a letter of mine (March 23, 1946, p. 444) I referred to the various factors involved and pointed out the fallacies of the Malthusian theory, which further experience continues to underline rather than otherwise. . . . In the pursuit of scientific knowledge (the vogue for which, one hopes, will become universal), discovery—and salvation—comes sometimes unexpectedly, and for problems of nutrition scientific agriculture, with its phenomenal increase of production and the synthesis of foods, offers much more solid ground for hopeful planning than a theory which was not only illogical in its conception but has entirely miscarried in its practice. Such a cliché as "the standard of living" must be used cautiously, and requires further analysis. Does it mean a nutritional standard, suitable clothes, hygienic dwellings, a happy married life, opportunities for education and cultivation of the arts, a high ethical standard, or does it mean a motor-car for everyone, consumption of alcohol and tobacco, extravagant clothes, disrupted family life, and visiting the cinema two or three times a week? At any rate apart from nutrition and hygiene every country is entitled to its own standards. It is impossible to see any strict relationship between "the standard of living" and the birth rate, yet this is frequently taken for granted.

Those who are staggered by the calculated increases of population should not neglect to note the considerably greater increases achieved in food production, and should take their refuge in scientific endeavour, which is also without limit. . . . Apart from scientific food production, intensive study is indicated of the operation of natural fertility in man, of heredity in its application to eugenics, and of the comparative social structure of different nations in relation to industry. These studies should be undertaken locally in different parts of the world, so that a variety of outlook and relevance to local conditions is ensured. If, after having done that, we should still feel bewildered and helpless, it will be better to admit that there is no solution than to hark back to a theory which is merely in the nature of a wish-fulfilment.

## Bodles for Dissection

Dr. W. J. PARAMORE (Bristol) writes: May I add to your reply to your correspondent that one way in which the deceased can prevail upon his executors to carry out any request as to the disposal of his body is to leave them a sum of money, conditionally upon his request being carried out. I believe I am correct in saying that a corpse is the property of the executors, if any are appointed, and not the relatives.

## Mind and Matter

Dr. W. J. CUDAHY (London, E.8) writes: I wonder whether E. R. Banner in his letter on the above subject (Sept. 13, p. 433) was aware that there is no evidence whatever to support McDougall's "law" or even Stapledon's? Indeed, there is a good deal of scientific evidence to establish the fact that life is never evolved from the inorganic. . . .

## Alien Doctors

Dr. W. H. SCOTT-EASTON (Frinton-on-Sea, Essex) writes: I read with much interest and some concern your leading article (Aug. 16, p. 258) on the Medical Practitioners and Pharmacists Bill. Are you quite sure that the real motive behind this Bill is not to supply a pool of aliens which can be used as a threat when the more mature of our British doctors show unwillingness to join the projected Health Service?

## Poliomyelitis

Dr. NORMAN MACFADYEN (Letchworth, Herts) writes: The infantile paralysis film should be withdrawn and reconsidered. The emphasis on the lumbar puncture is unfortunate. Lumbar puncture in most cases is unnecessary, may do harm, and certainly does not justify the cruelty of submitting a child with a rigid, stiff, painful, and tender neck and back to the contortions shown in the film. From the onset of the disease the patient should have absolute quiet and be in a position of relaxation of muscle and nerve. I think muscular exertion certainly increases the toxæmia.

## L. CARNAC RIVETT, M.Chir., F.R.C.S., F.R.C.O.G.

Prof. F. J. Browne writes: The death of Louis Carnac Rivett leaves a gap in British gynaecology that will not soon or easily be filled. Your short and factual obituary notice conveys but little idea of the vivid, versatile, and beloved personality so familiar to his friends. Of surgical technique he was a superb master, and his manual dexterity and lightness of touch made an operation performed by him a delight to watch. On many occasions the writer sent foreign visitors to him with a note of introduction, knowing that they would there see the best in gynaecological surgery that London had to offer. They were always received with kindness and courtesy. Naturally somewhat shy and diffident, while holding strong views of his own on many subjects, he seldom obtruded them in private conversation. Though he did not seem robust and must have been a very busy man, he never appeared hurried and found time to attend with remarkable regularity the meetings of the Section of Obstetrics and Gynaecology at the Royal Society of Medicine, where his contributions to the discussions never failed to add something of value to the common store. One illustration of his versatility was his understanding of old clocks, which he could restore to usefulness and accurate time-recording when the experts had failed. The domestic sorrows of the last two years, including the death of his only son from anterior poliomyelitis in China, were borne with courage, but one wonders how much they had to do with starting the dire disease that ultimately and untimely took away his life.

Dr. Kenneth Playfair, Chairman of the Medical Council of Queen Mary's Hospital for the East End, writes: In the obituary notice of the late Mr. Carnac Rivett (Sept. 13, p. 435), there is no mention of an interesting stage in his career. In 1919 Mr. Carnac Rivett was appointed honorary obstetrician and gynaecologist to Queen Mary's Hospital for the East End, and he remained on the active staff of the hospital until 1931. It followed that Mr. Carnac Rivett was head of the department in 1923 when the Margaret Lyle Maternity Wing of Queen Mary's Hospital (one of the largest maternity departments in London) was opened, and the department owes much to the fact that responsibility for the work was in his capable hands.

Dr. MICHAEL KEANE died suddenly in Switzerland on Aug. 14 at the age of 65. He qualified in Dublin in 1904, and after a period as house-surgeon at the Mater Hospital he joined the Regular Army and served for many years in India. He was mentioned in dispatches and awarded the O.B.E. towards the end of his service when he had reached the rank of lieutenant-colonel. He then went into general practice in Anerley, Kent. After fourteen years in this area he retired, and his sudden death so soon afterwards has come as a shock to his many friends and patients in Anerley.

Dr. ARNOLD McMILLAN, who died on Aug. 20 at the age of 67, took the Scottish triple qualification in 1907. He was house-surgeon to the Brighton and Hove Hospital for Women and later to the Royal Sussex County Hospital, Brighton, and the Royal Albert Hospital, Devonport. Subsequently he joined his cousin, the late Dr. J. J. Wallace, in general practice at Lymington. During the 1914-18 war he was commissioned as a surgeon-lieutenant, R.N., and served in the North Sea and the Mediterranean theatres. After the war he returned to Kent and went into general practice again in New Romney and Dymchurch. He was part-time medical officer of health for the borough of Romney from 1920, and from 1935 he held a similar appointment for the Lydd district. He was also medical superintendent to the old Romney Isolation Hospital and for some time deputy coroner for the area. In the recent war he worked with the Civil Defence Joint Committee for the Romney Marsh area and was responsible for the organization of A.R.P. work locally. For many years he had been a member of the British Ornithologists Union, and he was interested also in archaeology and philately.

Dr. LANCELOT RAOUL LEMPRIERE died at his home in Ware, Herts, on Aug. 28, at the age of 75. Coming from an old Jersey family (he was the son of Capt. Percy Lempriere), he was educated at Haileybury College, Worcester College, Oxford,

and Victoria College, Manchester, and after graduating in 1899 he held resident appointments at Manchester Royal Infirmary and at Crumpsall Infirmary and Children's Hospital. During the 1914-18 war he served as a captain with the R.A.M.C. He was the medical officer at Haileybury College for thirty-five years and was at one time president of the Medical Officers of Schools Association.

Mr. W. Donald Bedford writes: Lancelot Raoul Lempriere was a familiar and popular Hertfordshire figure whom everyone, and particularly Old Haileyburians of the last fifty years, will remember with esteem. Always particularly interested in sport, he distinguished himself especially in gymnastics—he won the All England Public Schools Gymnastic Competition in 1890 and the Silver Medal at Aldershot in 1891. He was also captain of the Worcester College football team and played hockey for Lancashire. He was a good tennis and squash player, and up till his death he thoroughly enjoyed judging the boxing and diving contests at Haileybury. He was appointed medical officer to Haileybury College in 1903 and remained in that capacity for thirty-five years, with a four-year break of military service in the first world war, for which services he received the O.B.E. and the "Médaille des Epidémies." He was president of the School Medical Officers' Society from 1924 to 1927, and was on the committee which drew up the "Code of Rules for Prevention of Infectious Diseases in Schools," which is still in general use. He was a member of the Psycho-analysis Committee of the B.M.A. in 1929. Recently he was president of the Herts County Hospital Medical Society. From 1939 onwards he wrote the Old Haileyburian's letter in the college magazine and completed his last one on his deathbed. To every Old Haileyburian prisoner of war he wrote four letters a year and was responsible for their parcels, etc. During the school vacations it was Lempriere's great delight to act as ship surgeon or as locum for many of the local doctors, and if he had any regrets in his school practice it was because, to quote his words, "he missed the personal contacts with ordinary people in general practice." Lempriere was indeed a fine character, and 20 years' contact with him made one appreciate more and more his absolute integrity, his kindness, and his conscientiousness, which he carried to an extreme degree. He would frequently sit up all night with an ill boy. To have a consultation with Lempriere was always a great pleasure.

Dr. ISABELLA MACDONALD MACDONALD, who died on Sept. 2 in London at the age of 91, was one of the first few women in this country to qualify. She was a daughter of the late Mr. John Macdonald, town clerk of Arbroath. A student at the London School of Medicine for Women, she took the L.S.A. and the London M.B. in 1888 and shortly afterwards was appointed resident physician at the Cama Hospital, Bombay. Unfortunately, after only three years' work there she had to resign because the climate had affected her health. She returned to London and in due course became senior physician and later consultant physician at the Elizabeth Garrett Anderson Hospital. In 1925 her friends and patients presented the hospital with a portrait of her in recognition of her outstanding work there. Dr. Macdonald was also a medical referee for the Baptist Missionary Society, and she continued in practice until her house in Seymour Street, Portman Square, was wrecked by a landmine in 1940.

Prof. Major Greenwood, F.R.S., writes: One of the amateurs of medical history who are grateful to Dr. Brock may perhaps be permitted to add a few sentences to the obituary notice in the *Journal* of Sept. 13 (p. 436). Dr. Brock was the only member of our profession who has made it possible for an English reader whose Greek and Latin are vestigial or, now that both the "learned languages" are optional, rudimentary to read Galen for himself. His edition of Galen, *On the Natural Faculties*, in the Loeb series, to which you refer, is invaluable to either class of reader. Those with vestiges of Greek grammar—people like me—using his readable translation can follow the text pretty well; the others can form a fair idea of the style, literary and scientific, of the old Dictator of Medicine. They can see why Dr. Brock said that Galen reminds one of another even more famous writer of Hellenistic Greek, the apostle Paul. Dr. Brock published another valuable book, *Greek Medicine* (London, 1929: J. M. Dent), which includes spirited translations from other works of Galen. Were it not for Dr. Brock, "Galen" would be really a sealed book to, say, 80% of medical readers. The only complete translation is into Latin, and not, as scholars tell us, a good translation. Yet Galen's influence is not extinct. We can all raise our eyebrows when we read (in a popular manual) an account of his incorrect physiology and mythical pathology, but we still believe, and do well to believe, much that Galen taught.

## Universities and Colleges

### UNIVERSITY OF LONDON

Gordon Macaulay Frizelle, M.D., has been appointed Assistant Dean of the London School of Hygiene and Tropical Medicine.

### UNIVERSITY OF WALES

#### WELSH NATIONAL SCHOOL OF MEDICINE

Ralph Montgomery Fullarton Picken, M.B., Ch.B., D.P.H., Mansel Talbot Professor of Preventive Medicine and Acting Provost of the Welsh National School of Medicine, has been appointed Provost of the School in succession to the late Col. A. W. Sheen. Prof. Picken was medical officer of health for Cardiff from 1921 to 1933 and was a member of the Council of the British Medical Association from 1930 to 1945, when the work attached to his appointment as Acting Provost of the School caused him to resign. When, in 1942, Mr. H. S. Souttar, then Chairman of the Council of the B.M.A., became chairman of a mission to report on the medical services for the armed Forces in India, Prof. Picken was appointed to act as Chairman of the Council in Mr. Souttar's absence.

### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

A lecture on "Some Aspects of the Anatomy of the Pelvic Floor" will be delivered by Mr. Frederick A. Maguire, honorary gynaecologist, St. Vincent's Hospital, Sydney, Australia, at the College House (58, Queen Anne Street, London, W.) on Wednesday, Oct. 1, at 5 p.m. All Fellows and Members of the College and other doctors interested in the subject are invited to attend the lecture. Admission to which is by ticket only, obtainable from the secretary of the College. Tickets will be allotted in the order of application.

### SOCIETY OF APOTHECARIES OF LONDON

A course of twenty postgraduate subscription lectures on modern therapeutics will be delivered in the Hall of the Society (Black Friars Lane, Queen Victoria Street, E.C.) during October and November, beginning on Oct. 13, at 5 p.m. The fee for the whole course is £10 10s. (£8 8s. for Members and Diplomates of the Society), or 15s. for a single lecture. Full particulars may be obtained from the registrar of the Society at the above address.

## Medico-Legal

### MORPHINE IN A PATENT MEDICINE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A father in Gorton, Manchester, bought three bottles of "Johnson's Celebrated Infants' Preservative" with which to treat his younger son for wind. The elder boy found an open bottle and drank half the contents; before long he became ill, and he died in Ancoats Hospital the next day. Dr. P. B. Woolley, a resident medical officer, produced the bottle, which the parents had handed to him, and said that the full contents would have contained just under 1 gr. (65 mg.) of morphine, a fatal dose for a child aged 2. The deputy coroner, Dr. Stanley Hodgson, asked him if he had any other experience of "this pernicious rubbish," and he answered that if a drug contained less than 0.2% of morphine it was not covered by the Dangerous Drugs Acts. The deputy coroner observed that doctors were told that morphine was most dangerous to children; in his opinion it was criminal that this sort of medicine was sold indiscriminately to parents who were not warned that it could be just as poisonous as carbolic acid.

The exception to which Dr. Woolley referred is contained in the Dangerous Drugs Regulations, 1937 (S.R.O. 560), which allow the free sale of preparations, admixtures, or other substances containing not more than 2.5% of methylmorphine or ethylmorphine (calculated as pure drug) associated with other medicinal substances.

The manager of the firm which manufactures the drug said to a Press reporter that the firm had been selling it for over a hundred years. He denied that each bottle contained a grain of morphine, and referred to the formula on the label giving the content as 0.432 gr. (28 mg.). No evidence of analysis was given at the inquest.

No. 36

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 6.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis and Polio-encephalitis

The number of cases of poliomyelitis in England and Wales notified during the week ended Sept. 13 was 572, as against 662 in the previous week, and the number of notifications of polio-encephalitis was 42 (46).

In London the decline in the notifications of poliomyelitis mentioned last week (Sept. 20, p. 473) continued; the figures for the last four weeks are 115, 77, 69, 63. In most other counties there were varying declines not obviously related to geographical situation. There were increases in Bucks 2 (0), Cornwall 4 (0), Cumberland 7 (2), Derby 8 (5), Devon 11 (5), Hereford 6 (1), Hertford 12 (9), Hunts 3 (1), Leicester 15 (11), Lines (Kesteven) 7 (1), Northampton 7 (5), Salop 5 (1), Southampton (Hants) 11 (5), E. Sussex 9 (6), W. Sussex 7 (5), Isle of Wight 7 (4), Isle of Ely 1 (0), Cardigan 1 (0), Carmarthen 1 (0), and Brecon 1 (0).

It is obviously too early to attempt to forecast the probable future trend of notifications, but the reduction of 90 over the country as a whole is encouraging.

**Clinical Records.**—One of the fundamental problems of the epidemiology of poliomyelitis is how the virus gets its teeth, and it is suggested that a study of outbreaks which have occurred, or may occur, in semi-isolated communities, such as residential schools and children's homes, at different stages of the general high prevalence might throw some light on this problem. The essential object of the inquiry would be to find out how the disease behaves in such communities at different seasons of the year. These communities have been chosen because it should be easy to determine the number of sub-clinical cases (see our annotation on this subject, Sept. 13, p. 423) occurring, an investigation which could only be undertaken with difficulty in the general population.

Doctors who have had, or may have, to deal with outbreaks in semi-isolated communities, and particularly school medical officers, are asked to supply in the first instance a short statement as to the approximate date of the outbreak, population at risk, and the number of definite and doubtful cases. This would make it possible to decide whether more detailed investigation would be likely to contribute to the solution of the problem. Subsequently it may be useful to collect information in a more or less standard form for ease of analysis. It would also be helpful if the Ministry of Health could be informed immediately a first case appears in a previously unaffected, semi-isolated community.

Information about such cases and records of earlier outbreaks in semi-closed communities should be forwarded directly to S.M.O., Med. III, Ministry of Health, Whitehall, London, S.W.1.

**Post-mortem Material.**—In addition to specimens in glycerol saline for the virus reference laboratory, Colindale, it is requested that representative specimens of spinal cord, as much as possible of the brain stem, and pieces of cortex including the motor area be preserved in formal saline and sent either to Prof. J. McIntosh, Middlesex Hospital, Mortimer Street, London, W.1, or to Dr. J. G. Greenfield, National Hospital for Nervous Diseases, Queen Square, W.C.1.

## Food-poisoning in Perthshire

Two outbreaks of food-poisoning have occurred in Perthshire in recent weeks. On Aug. 31 a party of 60 had a meal at 6 p.m.; and between 7 p.m. and 10 p.m. 56 of the party became ill, 4 being detained in hospital. Evidence pointed to tainted corned beef, which had been opened and served immediately. When seen next day the meat appeared to be perfectly sound, but on examination the outer surface was found to be heavily contaminated with *Staphylococcus aureus*. The tin concerned was one of a consignment which had been distributed all over the area, mainly in small portions, but no further cases appeared.

On Sept. 6, in almost the same area, another outbreak occurred, but in this case the food in question was found to be cream buns, and the causal organism *Salmonella aertrycke*. Approximately 120 persons were affected, with one death. Most of the cases were fairly mild, and, since in these cases there was some delay in obtaining medical advice, the true position did not become apparent until the fourth day. Fortunately two of the cream buns were discovered on the sixth day, and from these, as from the faeces of some of the cases, *Salmonella aertrycke* was demonstrated. The cream in question was widely distributed over the country, and it was made up in the usual way. There have been no reports of cases elsewhere, and the source of the contamination in this instance is not known.

### Discussion of Table

In *England and Wales* there was an increase in the number of notifications of scarlet fever 104, acute poliomyelitis 50, and whooping-cough 65, and a decrease in the incidence of measles 667, dysentery 21, and diphtheria 19.

An increased incidence of whooping-cough was recorded in most areas of the country; the largest local increases were in Lancashire and Staffordshire, where rises of 59 and 40 were reported. There were only a few areas which provided exceptions to the general decline in the incidence of measles; the largest falls were Glamorganshire 67 and Monmouthshire 50.

The chief feature of the returns for diphtheria was a decrease of 12 in Warwickshire. In Bedfordshire 12 further cases of paratyphoid fever were notified; 47 cases have been notified from this outbreak in the past four weeks. An increase of 10 in the notifications of dysentery was recorded in Lancashire; the largest local centre of infection in the country during the week was Liverpool C.B. 10.

In *Scotland* an increase was recorded in the notifications of scarlet fever 30, dysentery 11, and diphtheria 5. A decrease of 14 was recorded for cases of whooping-cough. The rise in the notifications of dysentery was due to isolated cases, and no large outbreak of any size was reported. Diphtheria was less prevalent in most areas, but a rise of 19 occurred in Glasgow. The increase in cases of scarlet fever was contributed by the western area.

An outbreak of gastro-enteritis in the village of Kineardine O'Neill has affected almost half of the 182 inhabitants. The outbreak was due to the milk from one cow, which subsequently died.

In *Eire* decreases were recorded for diarrhoea and enteritis 11, and measles 20, while the notifications of whooping-cough increased by 15.

In *Northern Ireland* the trends of infectious diseases did not show any large variations.

### Week Ending September 13

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 674, whooping-cough 1,519, diphtheria 162, measles 1,038, acute pneumonia 203, cerebrospinal fever 25, acute poliomyelitis 572, acute poliomyelitis 42, dysentery 69, paratyphoid 14, and typhoid 13.

## Medical News

### Cancellation of Harveian Dinner

The Royal College of Physicians of London announces that, in view of the Government's decision about dinners, it has reluctantly decided to cancel the Harveian Dinner, arranged for Oct. 18.

### Middlesex Hospital Medical School

The Middlesex Hospital Medical School, desiring to fall in with the Government's expressed wish regarding dinners for large numbers of people, has cancelled the annual dinner of the School which had been arranged for Oct. 2 at the Savoy Hotel.

### Dr. C. Hill as Luton Candidate

Dr. Charles Hill, Secretary of the B.M.A., was on Sept. 23 unanimously chosen as prospective Parliamentary candidate of Luton United Liberal and Conservative Association for the Luton Division.

### The Osler Club

The Osler Club of London, which was founded in 1928, is to be revived. The objects of the club are to encourage medical students to link the history of their art with their professional work and to keep alive the memory of Sir William Osler. Those interested should write to the Acting Secretary, Dr. A. White Franklin, 11, Wimpole Street, London, W.1.

### Territorial Army

The following Territorial Army medical units have re-formed in the London area. There are vacancies for specialist and non-specialist medical officers and for warrant officers, N.C.O.s, and men. Anyone interested in joining one of these units should apply to the officer commanding: 2 (London) General Hospital, Elmgrove Road, Harrow (Tel.: Harrow 6890); 167 and 168 (City of London) Field Ambulances and 24 (London) General Hospital, 57a, Farringdon Road, E.C.1 (Tel.: Holborn 2536); 10 and 17 (London) General Hospitals, 8 (London) Field Hygiene Company, and 4 (Para) Field Ambulance, Duke of York's Headquarters, Chelsea, S.W.3. There are also vacancies for Territorial Army regimental medical officers in various parts of London. Application should be made to the D.A.D.M.S., 13, Eccleston Square, S.W.1, or to the O.C. unit concerned.

### Care of Old People

At the first meeting of the governors of the National Corporation for the Care of Old People, at which Sir George Wilkinson, Bart., presided, it was decided to appoint an Advisory Council to make recommendations on the policy and activities of the Corporation and to examine all applications for grant-aid. The Hon. Geoffrey Gibbs, C.M.G. (vice-chairman of the Corporation), will be the chairman and Mr. L. Farrer-Brown, J.P., the vice-chairman of this Council. The following have agreed to serve, in their personal capacities, as members of the Advisory Council: Mr. H. Fieldhouse, C.B., O.B.E.; Mr. D. H. W. Hall; Mr. A. W. Hersee, O.B.E.; Alderman Mrs. A. V. Hill; Mr. Howell James; Sir Geoffrey King, K.B.E., M.C.; Mr. Fred Messer, J.P., M.P.; Sir Ernest Rock Carling, F.R.C.P., F.R.C.S.; Miss E. L. Younghusband, M.B.E., J.P. Mr. Allendale Sanderson was appointed secretary of the Corporation.

### Radio-isotopes for Research

President Truman announced on Sept. 3 that the U.S.A. will make radio-isotopes for medical and biological research available to workers in other countries. Distribution will be directed by the U.S. Atomic Energy Commission. Governments whose research workers request radio-isotopes must agree to (1) make progress reports to the A.E.C. every six months, and permit publication of reports; (2) ensure that radio-isotopes are used for the purpose stated in the request, which must be approved by the A.E.C.; and (3) permit qualified scientists, irrespective of nationality, to visit institutions where the materials will be used, and to obtain information freely. U.S. laboratories and research groups wish foreign scientists to visit institutions in the U.S.A. where medical and biological research with radio-isotopes is being conducted. Governments whose workers require radio-isotopes must designate representatives in the U.S.A. to file requests and pay for the materials, and assume responsibility for safe handling in transit outside the U.S.A. The A.E.C. will publish a catalogue of the substances obtainable and their prices. The following radio-isotopes are available: antimony<sup>122 124 125</sup>, arsenic<sup>74 77</sup>, bromine<sup>82</sup>, calcium<sup>45</sup>, carbon<sup>14</sup>, chlorine<sup>36</sup>, cobalt<sup>60</sup>, copper<sup>64</sup>, gold<sup>198 199</sup>, iodine<sup>131</sup>, iron<sup>59 55</sup>, mercury<sup>197 203 205</sup>, phosphorus<sup>32</sup>, potassium<sup>42</sup>, silver<sup>110 111 115</sup>, strontium<sup>90</sup>, sulphur<sup>35</sup>, sodium<sup>24</sup>, zinc<sup>65 66</sup>.

### Algiers Surgeon's Visit

Prof. Pierre Goinard, head of the neurosurgery centre at the Barbier-Hugo Hospital, Algiers, is visiting Britain under the auspices of the British Council to study psychiatric and neurosurgical centres.

### Wills

Dr. Reginald John Gladstone, formerly reader in anatomy at King's College, London, who died on Feb. 12, left £42,182. Dr. Thomas William Shore, dean of St. Bartholomew's Hospital Medical College 1906-30, who died on Feb. 19, left £17,357. Dr. Arnold Lyndon, a former Vice-President of the B.M.A., who died on Nov. 14, 1946, left £44,652. Dr. George Fogg, of Newcastle-upon-Tyne, left £2,046; Dr. Walter Wingfield Nuttall, of Folkestone, Kent, left £34,946; and Dr. Edward John Macartney Watson, of Dublin, left £43,133.

## COMING EVENTS

### Cambridge Medical Graduates' Club

It is hoped to revive the activities of the Cambridge Medical Graduates' Club with a sherry party at the Apothecaries' Hall (Black Friars Lane, Queen Victoria Street, London, E.C.) on Thursday, Oct. 30. As the secretaries of the club have been unable to trace a large number of old members, all who have not received notices should communicate with Dr. R. A. Hickling, of 99, Harley Street, London, W.1. The subscription to this mainly social club is £1 ls. for life membership. There have been no new members since 1939. All Cambridge medical men are eligible for election, and those who have qualified since 1939 are urged to get in touch with their hospital representative or with Dr. Hickling.

### Royal Free Hospital School of Medicine

Prof. Ida Mann, F.R.C.S., will present the prizes of the Royal Free Hospital School of Medicine and will deliver the 1947-8 inaugural address on "The Possibilities of a Medical Education" at B.M.A. House, Tavistock Square, London, W.C., to-day (Friday, Sept. 26), at 3 p.m.

### Films on Penicillin and Anterior Poliomyelitis

The Chelsea and Fulham Division of the B.M.A. has arranged for the following films to be shown on Friday, Oct. 3, at 8.15 p.m. at Fulham Hostel, 367, Fulham Road, S.W. (1) Penicillin, to be introduced by Dr. P. Harvey, Mr. J. Cooper Brass, and a pathologist; (2) Anterior Poliomyelitis, to be introduced by Dr. W. H. Kelleher. All medical practitioners are invited to attend.

**Shropshire and Mid-Wales Branch of the B.M.A.**

A clinical meeting of the Shropshire and Mid-Wales Branch of the B.M.A. will be held at King Edward VII Memorial Sanatorium for Shropshire, Shirlett, nr. Broseley, on Tuesday, Sept. 30, at 3.30 p.m.

**Mid-Essex Division of the B.M.A.**

A meeting of the Mid-Essex Division of the B.M.A. will be held at Chelmsford and Essex Hospital on Sunday, Oct. 5, at 11 a.m., when Mr. H. A. H. Harris and Dr. James Hall will read a paper on "Rehabilitation in Hospital and General Practice."

**Welsh National School of Medicine**

The opening Sessional Address of the Welsh National School of Medicine will be given in the school on Tuesday, Sept. 30, by Prof. Harry Platt, M.D., M.S., F.R.C.S., F.A.C.S., professor of orthopaedic surgery in the University of Manchester, on "Medicine, Science and Learning."

**Medical Society of the L.C.C. Service**

A meeting of the Medical Society of the L.C.C. Service will be held at County Hall, Westminster Bridge, S.E., on Thursday, Oct. 2, at 4 p.m., when Prof. John A. Ryle, M.D., F.R.C.P., will open a discussion on "The Social Aspects of Hospital Work."

**National Association of Insurance Committees**

The thirtieth annual meeting of the National Association of Insurance Committees will be held at B.M.A. House, Tavistock Square, London, W.C., on Thursday, Oct. 2, at 3 p.m., when the proceedings will be opened with an address by the Rt. Hon. Aneurin Bevan, Minister of Health. The meeting will be continued on Friday, Oct. 3, at 10 a.m.

**Royal College of Obstetricians and Gynaecologists' Dinner**

The Royal College of Obstetricians and Gynaecologists has arranged a dinner to be held at the Connaught Rooms, Great Queen Street, London, W.C., on Friday, Oct. 3, at 7 p.m. for 7.30 p.m.

**Royal Sanitary Institute**

A meeting of the Royal Sanitary Institute will be held at Chester Town Hall on Friday, Oct. 3, at 10.45 a.m., when Dr. Arnold Brown will read a paper on "The Administrative Aspects of the Care of Children."

**King's College Hospital Medical School**

The opening of the one hundred and eighteenth session of King's College Hospital Medical School will take place at the School, Denmark Hill, S.E., on Friday, Oct. 3, at 3 p.m. The Dean will present the scholars and prize-winners to Sir Edward Mellanby, K.C.B., D.Sc., M.D., F.R.C.P., who will deliver the Introductory Address. Surgeon Rear-Admiral Sir Cecil Wakeley, K.B.E., C.B., D.Sc., F.R.C.S., will preside.

**Westminster Hospital Medical School**

Sir Adolphe Abrahams will deliver the inaugural address at the Westminster Hospital Medical School, 17, Horseferry Road, S.W., on Monday, Oct. 6, at 3 p.m.

**Road Safety**

The Royal Society for the Prevention of Accidents will hold its Silver Jubilee Congress at Brighton on Oct. 7-10. Among the subjects discussed will be one on the "Psychological Aspects of Child Road Accidents" by Dr. K. Soddy on Oct. 8.

**Chadwick Lectures**

The following Chadwick Public Lectures have been arranged: Tuesday, Oct. 7, 2.30 p.m., at Royal Society of Tropical Medicine, 26, Portland Place, W., Brigadier A. E. Richmond, "Positive Health—Its Attainment in the Soldier, and the Army's Contribution to it in the Civilian"; Tuesday, Nov. 4, 2.30 p.m., at London Missionary Society, 42, Broadway, Westminster, S.W., Dr. C. T. Maitland, "Hospitals and Health Services"; Thursday, Dec. 4, 4.30 p.m., at St. Mary's Hospital Medical School, Norfolk Place, Praed Street, W., Dr. G. B. Mitchell-Heggs, "Some Changes in Dermatology since the time of Sir Malcolm Morris." Admission to the lectures is free, and further particulars may be had from the secretary of the Chadwick Trust, 204, Abbey House, Westminster, S.W.1.

**Training of Specialists**

Sir Francis Fraser, M.D., F.R.C.P., will deliver the annual address on "The Training of Specialists: The Place of Postgraduate Institutes," at a meeting of the Institute of Laryngology and Otology, at 330, Gray's Inn Road, W.C., on Friday, Oct. 10, at 4.30 p.m.

**SOCIETIES AND LECTURES**

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Monday, Sept. 29, 5 p.m. Hunterian Lecture by Prof. Hassan Ibrahim, Bilharziasis and Bilharzial Cancer of the Bladder. Tuesday, Sept. 30, 5 p.m. Hunterian Lecture by Prof. Harold Wookey, Senior Surgeon, Toronto General Hospital, Surgical Treatment of Malignant Disease of the Pharynx and Oesophagus.

**ROYAL SOCIETY OF MEDICINE**

Section of History of Medicine.—Wednesday, Oct. 1, 2.30 p.m. Presidential Address by Dr. Hubert J. Norman: History of the Treatment of Mental Disorders.

Section of Neurology.—Thursday, Oct. 2, 8 p.m. Clinical meeting at the National Hospital, Queen Square, W.C.

**POSTGRADUATE DIARY**

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—Wednesday, Oct. 1, 8 p.m., Dr. J. D. Fraser: Industrial Cataract.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Thursday, Oct. 2, 5 p.m. Dr. G. B. Mitchell-Heggs: Pyogenic Affections.

PHYSICAL SOCIETY: COLOUR GROUP.—At Small Physics Lecture Theatre, Imperial College, Imperial Institute Road, London, S.W., Wednesday, Oct. 1, 3.30 p.m. Review and discussion of International Colour-Vision Conference held at Cambridge in July, to be opened by Mr. J. G. Holmes and Mr. R. G. Horner.

A series of special Honyman Gillespie lectures has been arranged, in association with Edinburgh postgraduate courses, to be given in the West Medical Theatre, Edinburgh Royal Infirmary, on Thursday, at 4.30 p.m., from Oct. 16 to Nov. 27, both dates inclusive. The lectures are open to all graduates and senior students. Details will be published in the diary column of the *Journal* week by week.

A course of lectures and demonstrations will be held at the London Chest Hospital during the winter term on Fridays from Oct. 17 to Dec. 19, all at 5 p.m. with the exception of the lecture and demonstration on Dec. 12, which will be given at 6 p.m. A second course will be held during the spring term from Jan. 9 to March 12, 5 p.m. Admission will be by ticket only and the fee for each term is £2 2s., except for serving and demobilized members of H.M. and Allied Forces. Applications should be addressed to the Dean, London Chest Hospital, Victoria Park, E.2.

The next clinico-pathological demonstration will be held in the Meyerstein Lecture Theatre of the Westminster Hospital School of Medicine, Horseferry Road, S.W., on Monday, Oct. 13, at 5 p.m., and not on Oct. 6 as announced in the *Journal* of Sept. 20 (p. 474). The subject under discussion will be Anterior Poliomyelitis.

**APPOINTMENTS**

Mr. George Laws, M.B.E., will take office as chairman of the Council of the Royal Sanitary Institute on Oct. 1.

Dr. Alan Trevor Jones, of Cardiff, has been appointed Senior Administrative Medical Officer of the Welsh Regional Hospital Board.

Dr. Trevor Jones is a medical officer under the Welsh Board of Health.

Dr. Alexander Boyd Williamson, O.B.E., has been appointed Senior Administrative Medical Officer of No. 2 Regional Hospital Board, with headquarters at Leeds.

Since 1934 Dr. Williamson has been Medical Officer of Health for Portsmouth.

GILMOUR, DAVID, M.B., Ch.B.Ed., D.P.M., Deputy Medical Superintendent, Birmingham City Mental Hospital, Winson Green.

**BIRTHS, MARRIAGES, AND DEATHS**

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

**BIRTHS**

DOHERTY.—On Sept. 11, 1947, at Cardiff, to Eva (née Kennedy), wife of Dr. C. J. Doherty, a daughter.

ELMES.—On Aug. 20, 1947, in Dublin, to Margaret (née Dutton), wife of Dr. F. Elmes, East Waylands, Hayes End, Middlesex, a daughter—Penelope.

MALLINSON.—On Sept. 9, 1947, at St. George's Hospital, S.W.1, to Ella, wife of Sir Paul Mallinson, a daughter.

**MARRIAGES**

AIRTH.—MACLENNAN.—On Aug. 30, 1947, at the Naval Chapel, Portland, Graham Robertson Airth, to Patricia Ann MacLennan.

WILSON.—WEST.—On Sept. 6, 1947, at St. Mary's Church, South Hayfield, William Eric John Wilson, B.Sc., M.B., Ch.B., to Emily Florence West, S.R.N.

**DEATH**

JOHNSON.—Charles, M.B., B.S., F/O, R.A.F. Only son of Mr. and Mrs. C. W. Johnson of 196, Sunderland Road, South Shields. In a flying accident on Sept. 17, 1947, at 12.15 p.m. at Aekington Airfield, Northumberland.

MEYER.—On Sept. 5, 1947, at 80, Trafalgar Road, Birmingham, Fritz Meyer, M.D. Berlin, aged 62, after a long illness.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions. Each should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Diphtheria Immunization

**Q.**—There was a survey some time ago of the results of diphtheria immunization over a period. This showed the highest percentage of lasting immunity from an initial dose of 0.25 ml. A.P.T., and apparently stressed that this dose should be as high as possible (that is, not less than 0.2 ml.). The initial dose was the deciding factor in the percentage of lasting immunity gained. If this is so, can a reinforcing dose be justified if it gives no more than transient immunity in those who lose their immunity rapidly?

**A.**—For the production of antibody, as in the active immunization of children against diphtheria, the first injection of antigen, called the "primary stimulus," serves mainly to prepare or sensitize the antibody-producing cells so that when the second antigen—the "secondary stimulus"—is given there is a rapid outpouring of antibody. It is important that this first dose should be large enough to prepare the antibody mechanism for the response which it should give when the second dose, which may be much smaller, is administered. Thus it is theoretically wrong to give a small first dose and a larger second dose, as is common practice in this country, although a dose of 0.1–0.2 ml. of A.P.T.—a very good antigen—has been found to be an adequate primary stimulus, since when the second dose is given the Schick conversion rate is practically 100%. The production of antibody in response to the second dose is maintained at a high level for a short period, and then shows a steady decline so that in two to three years demonstrable antibody may be absent from the blood. This happens irrespective of the size and nature of the primary stimulus, although the fall may occur earlier with one kind of antigen than with another; for example, the Schick reversion rate, which means loss of immunity, is higher and occurs more quickly after immunization with two doses of T.A.F. than with A.P.T. When the antibody has dropped to a very low level the boosting dose given one year or more later acts in the same way as the secondary stimulus, so that there is again a rapid production of antibody, which may reach even higher levels and persist for a longer period than is the case after the first immunizing course. This boosting dose should therefore not be omitted even if the primary stimulus was a particularly good one.

### Treatment of Rheumatoid Arthritis

**Q.**—I was interested in Dr. Imre Barsi's article (*Journal*, Aug. 16, p. 252) on the treatment of rheumatoid arthritis by the transfusion of citrated blood from a pregnant woman. Realizing the difficulties, I wondered if an alternative to such a method had been tried, by the use of, say, the intramuscular injection of chorionic gonadotrophin. I propose to try one or two cases on a dosage of 100 i.u. I should be grateful for your comments.

**A.**—The treatment of rheumatoid arthritis by the transfusion of blood from a pregnant woman has not been tried, so far as we are aware, by anyone except the author of the article referred to. The difficulties inherent in such a method in this country are obvious, and the idea of using chorionic gonadotrophin has occurred to others and is likely to be the subject of trial. It must be regarded as purely experimental at the present stage, and the results should be carefully watched and recorded; under such conditions it would be justified. The dosage suggested would be appropriate in the first instance and might be modified in the light of experience in the direction of either increase or decrease; possibly courses of a few doses with intervals over a period of twelve months would furnish useful information; a shorter period of observation would be less reliable.

### Removal of Cyst from Hand

**Q.**—I wish to remove a small swelling the size of a cherry stone in the right palm of a girl aged 3. It appears to be an epidermoid or mucous cyst. How long can a pneumatic blood-pressure band for the control of haemorrhage be safely applied, and what special points in operative technique are to be emphasized?

**A.**—It is perfectly correct technique to remove the cyst described under a general anaesthetic and with the use of a pneumatic blood-pressure band for the control of haemorrhage, but the time factor should not enter into the picture. The band can safely be left on without release for half an hour or more, and it is unlikely that the operation will take half this length of time. Tourniquets of all descriptions can in fact be left on much longer than is stated in the average textbook or first-aid manual. This fact was amply proved in dealing with the casualties of the last war. But if circumstances demand the retention of a tourniquet over long periods, release for only a few moments at half-hour intervals renders the procedure perfectly safe. The following points in technique may be noted. Use a sharp scalpel—sharp to the point; do not undercut the skin too near to the epidermis; tie obvious vessels if injured, despite the fact that they are not bleeding; avoid cutaneous branches of digital nerves; sew up skin with interrupted fine silkworm-gut sutures; apply a pressure dressing.

### Retarded Speech Development

**Q.**—Can you suggest any treatment for a boy aged 4½ years who has only a limited vocabulary of simple words? Health and intelligence good, hearing and memory excellent. The child is sociable and very musical, singing any tune perfectly after two or three hearings. He will not imitate words or phrases, however, and speech therapy had no success owing to his lack of co-operation.

**A.**—It is difficult to advise in this case without knowing the results of certain tests. Some children develop speech normally after a late start, especially "only" children, or a first child who is not succeeded by another for several years. On the other hand, there may be some defect of hearing, such as high-frequency deafness that cannot be detected without an audiometer test, or an auditory imperception. Tests for the latter condition can be carried out by psychologists in certain clinics. If this child's speech development is not affected by any organic abnormality the causation may be psychogenic. If so, it is important not to urge him to speak. Since he is musical, it may be possible to introduce words into the tunes that he learns. It will also help if adults are careful to use only clear and slow speech when addressing him, and a consultation at a child-guidance clinic would be useful to find out if there is any emotional conflict that would account for his retardation in the use of words.

### Decay of Finger-nails

**Q.**—Is any treatment effective in preventing the dry decay, with occasional shedding, of finger-nails seen sometimes in elderly people? Is it always worth while to ask a pathologist to examine scrapings for possible fungus infection?

**A.**—Scrapings should always be examined for fungus, but if most nails are affected the condition is probably dystrophic from general causes, if not part of a skin disturbance such as psoriasis. Attention should be directed to the cause. Fractional doses of x rays may be given to the nail matrices.

### Eye Surgery in Animals

**Q.**—What means should be adopted to ensure relaxation and fixation in a rabbit or cat so that an operation may be performed upon its eye?

**A.**—For minor operations the cornea and conjunctiva can be adequately anaesthetized by the instillation of drops of 2% cocaine solution. Intraocular manipulations call for analgesia either by retrobulbar injection (2 ml. of 5% procaine solution) or by intravenous or intraperitoneal injection of veterinary pentobarbitone soluble, 0.5 ml. per kilo of body weight. With general anaesthesia there is no difficulty in fixing the eye; with local analgesia the animal is best held by an assistant. It is unlikely that any operations can be carried out on the cat without general anaesthesia.

## Intramuscular or Subcutaneous Injections

**Q.**—*Intramuscular injections can be a nuisance to both doctor and patient. What is the objection to giving liver extract or penicillin subcutaneously? Relative slowness of absorption would often seem to be an advantage. The same applies to oily solution of progesterone and oestradiol. One firm recommends that progesterone be given intramuscularly, and oestradiol "intramuscularly or subcutaneously." It is agreed that certain drugs are best given by special routes for speed of action or other reason, but does not the matter too often depend on the whim of the manufacturer?*

**A.**—Intramuscular injections are less painful than subcutaneous injections. This applies especially to all injections of volume greater than 1 ml., because more bulk causes pain. Again, many substances are irritant—for example, penicillin, cimetidine, etc.—and are well tolerated only if given intramuscularly. Finally, oily solutions or suspensions are very slowly and irregularly absorbed from subcutaneous depots and are liable to give rise to abscess formation.

## Exposure to Lead

**Q.**—*In a lead-smelting works a number of men developed a moderate punctate basophilia of between 3,000 and 5,000 cells per million. They were given work outside the factory, but a year later their high basophil counts persist. Does this imply that they must still be absorbing lead?*

**A.**—Punctate basophilia may persist for some time after exposure to lead has ceased, but it is important to ascertain if, in the case instanced, a source of lead exposure still exists. The possibility will be remembered, too, of the liberation into the blood stream of lead which has been stored in the body. Punctate basophilia (the size of the particles is worthy of note) is, of course, only a part of the picture, and a clinical examination of the group of men (and their fellow-workers) with a consideration of the blood condition as a whole should decide the question of whether lead absorption is continuing or not.

## Treatment of Psoriasis

**Q.**—*Can you give me any information about the Goeckerman treatment for psoriasis?*

**A.**—Goeckerman's name has been attached to a treatment of psoriasis in which a tar paste such as the following is applied at night and is cleaned off with oil in the morning and the patient is subsequently exposed to ultraviolet light in erythema dosage:

R					
Crude coal tar	..	..	..	gr. 20 (1.3 g.)	
Zinc oxide	..	..	..	gr. 120 (8 g.)	
Soft paraffin	..	..	..	ad 1 oz. (30 g.)	

Make into a paste.

## Lupus Vulgaris

**Q.**—*Is it safe for a young child to live in the same house as an elderly woman covered with dry red scaly lupus?*

**A.**—The danger of the spread of infection from lupus vulgaris is slight, but it is possible through an open wound of the skin, even though this is small. It would therefore be advisable for the child to refrain from direct contact with the patient. It is important that anything used in washing and bathing by an infected person should be kept separate.

## Disseminated Sclerosis

**Q.**—*In a case of advanced disseminated sclerosis what measures may be adopted to alleviate the severe and painful flexion contractures of knee and elbow?*

**A.**—Among medicinal agents worth trying are the barbiturate sedatives. Recently injections of curare have been used with slight temporary improvement at times. Some cases are relieved by light splints or by immobilization in plaster. Surgical attempts at relief have included tenotomy, Stoffel's operation, and even posterior rhizotomy. It must be confessed that flexor spasms often prove most obstinate despite all the foregoing measures. Thirty years or more ago preparations of conium were in vogue for this symptom, but the drug has passed out of fashion, and recent retrials have not been at all encouraging.

## NOTES AND COMMENTS

**Judicial Hanging.**—Dr. S. W. ALLWORTHY (Belfast) writes: The notes by Col. N. J. C. Rutherford (Aug. 16, p. 282) and Lieut.-Col. F. A. Barker (Aug. 30, p. 358) on procedure in Indian jails reminds me of the following historical note by the late Pres. J. K. Ingram, F.T.C.D., on hanging in England. "Hanging was made of execution in use among the Anglo-Saxons. Indeed *Beowulf*—which its able editor, Kemble, believed to be a form of a poem which the invaders of Britain had brought with them from their Continental homes—the gallows (*galga*) figures as an established institution of the Teutonic races of Northern Europe. But it is very difficult to get any definite information as to the history of hanging in England. It seems, however, quite certain that the idea of immediately extinguishing the life of the culprit by a sufficient fall never presented itself to our ancestors; their only notion was that of suspending him by the neck for what might seem an adequate time to ensure (?) strangulation. It is noticed by Blackstone as a somewhat singular fact that the only warrant the sheriff has for a capital execution is the signature of the judge; to the calendar or list of all the prisoners' names, with their respective judgments in the margin: formerly, in the days of Latin and abbreviation, '*sus per coll'*' for '*suspendatur per collum*'. Originally, however, he states there was a formal precept to the sheriff under the hand of the judge, but in none of the law books have I found a copy or exact description of this precept. I do not even find how long the sentence to be 'hanged by the neck till ye are dead' has been in use. 'It is clear,' says Blackstone, 'that, upon judgment to be hanged by the neck till he is dead, the criminal be not thoroughly killed but revives, the sheriff must hang him again for the former hanging was no execution of the sentence.' But strangely enough we find in the *Vision of Piers Plowman* a passage which seems to show that the opposite of this either was, or was believed to be, the established rule in his time:

"It is nought used on earthe  
To hangen a felon  
Ofther than ones,  
Though he were a tretour."

The Rev. Samuel Haughton, F.R.S., M.D. (Dubl.), D.C.L. (Oxon.) in his famous book on *Animal Mechanics* published in 1873, in digression on the art of hanging gave his own experiences and mathematical calculations with regard to the "long drop" and instantaneous death which he advocated. He says: "According to the original form of death punishment for treason in England, the hanging was used as an anaesthetic, preparatory to the disembowelling (or drawing) that always preceded the quartering of the criminal and the present slow process of hanging, practised by Calcraft and others in England and Scotland, which consists in dropping the patient through two or three feet and allowing him to hang until dead, is the faithful representation of the original process of hanging, which was intended to fulfil a purpose quite different and distinct from that of the speedy execution of the criminal. It seems to me unworthy of the present state of science to continue a mode of execution which as at present used is extremely clumsy, and also painful to the criminal. Instead of the 'short drop' used we ought to employ the 'long drop' which causes instantaneous death."

**Infantile Eczema.**—Dr. C. W. F. McKean (London, W.1) writes: True atopic infantile eczema should be distinguished from seborrhoeic dermatitis in infants (Sept. 6, p. 403). The latter is the far commoner condition. Soap and water should perhaps be avoided in the acutely red stage, when normal saline may be used for cleansing, if necessary, but olive and nrichis oil are definitely contraindicated, and will always worsen or prevent the cure of seborrhoeic conditions. Indeed, oils should be used with caution in all skin diseases.

**Correction.**—The courses of instruction for the Diploma in Tropical Medicine and Hygiene at the Liverpool School of Tropical Medicine for the years 1947-8 start at the end of August and the beginning of January, not as stated in our issue of Sept. 6, p. 39.

## AIR-BORNE INFECTION\*

BY

R. J. V. PULVERTAFT, O.B.E., M.D., F.R.C.P.

*Professor of Clinical Pathology, Westminster Hospital School of Medicine*

The conception of air-borne infection came thousands of years before the discovery of bacteria. As soon as man became an animal living in large settled communities epidemic disease was inevitable, and the most primitive intellect could grasp the significance of the unseen transmission of a fatal agent. The word "toxin" has carried on to the present day the Old Testament conception of an arrow flying in the darkness, and the mediaeval paintings of St. Sebastian continue the metaphor. Plague-stricken London anticipated Lister with fumes of brimstone; the judge still carries his posy of flowers to ward off jail fever; and the observations of Twort and his colleagues on the value of smokes as bactericidal agents must remind all who have visited Eastern bazaars of the itinerant incense carrier. Perhaps the use of incense in many religions had the neutralization of infection as one motive.

Eighteenth-century doctors, with their leisurely precision, made some guesses very near the mark. Sydenham wrote: "The matter so falls out that at this time or that time the air is furnished with particles that are adverse to the human body." Arbuthnot, in 1733, in *An Essay concerning the Effects of Air upon the Human Body*, said: "Nothing accounts so clearly for epidemical diseases seizing human creatures inhabiting the same tract of earth who have nothing in common that effects them except air" as that "air is the  $\pi\acute{o}\varsigma\ \theta\epsilon\iota\omicron\nu$  in disease." Air is the mysterious something of the ancients. It was indeed through experiments on air, still recalled to bacteriologists by their daily use of the Pasteur pipette, that the whole of modern bacteriology evolved. In his first classic paper Lister wrote: "The air owes the property [of putrefaction] to minute parasites suspended in it, which are the germs of various forms of life"; and Koch in one of his earliest papers wrote: "It is also highly probable that the tubercle bacilli are usually inhaled with the inspired air, clinging to particles of dust."

It is therefore not surprising to find that the early bacteriologists particularly studied the air. Flüge in 1897 put forward the conception of droplet infection, though it is only in comparatively recent years that the subject has again come to the forefront. Indeed, the early workers soon found that direct contact and contaminated instruments were in many cases far more important to the surgeons; and they lacked equipment capable of controlled measurement of the bacterial content of the air.

### Technical Methods

One of the oldest and simplest methods of culturing the air is to expose Petri dishes, and the method is still quite satisfactory. It is true that this gives no quantitative values, but the number of organisms falling on to a plate is proportional to the number in the air, and runs roughly parallel with more exact measurements. Quantitative estimates may be made by a simple technique devised by Elford: a piece of filter paper is placed in a Seitz filter, a known volume of air sucked through, and the disk dropped on to a semi-solid agar plate. For critical work, however, the air centrifuge of Wells or the slit sampler of Bourdillon must be used. It is possible to-day to give a reasonably exact estimate of the number of particles containing bacteria. The results of course vary according to conditions: probably the air is nowhere sterile, even at great heights. From personal observations it is found that a hospital ward normally has about fifty such particles per cubic foot, but when beds are made the number rises to 2,000-3,000. Bourdillon and Colebrook, using filtered air in a surgical dressing-room, found 0.005 particles per cubic foot; this figure rose to more than 600 when dressings were done without ventilation. Canteens were found to have up to 250. In air-raid refuges the bacterial content gradually rose nearly tenfold over a period of hours.

Experiments on animals are not entirely satisfactory. Mice can be infected by mists of influenza virus and of pasteurilla. Ferrets infected with influenza and virulent streptococci transmit the streptococci to ferrets, at the other end of an animal house, infected with influenza only; rabbits infected with tuberculosis transmit the infection to others at a distance. On the whole, however, air-borne infection has not lent itself to experiments of this type.

### General Principles

It is to be anticipated that certain forms of bacterial life would adapt themselves to aerial spread, as certain plants have winged seeds and as other bacteria adapt themselves, through their mobility, to aquatic life. The vast majority of air-borne organisms are non-pathogenic. The majority are resistant to desiccation owing to spore formation, and probably of low specific gravity. The universality of moulds is due to these factors. Moulds are of immense economic importance, and so versatile that they infest even cold-storage plants. Indeed, the control of mould infection offers great scope to the technique used in the control of infection, and appears to be neglected.

\* A lecture delivered at the Royal College of Surgeons of England.

On general principles, again, we should expect organisms which infect the respiratory tract to travel via the air. This, however, does not imply that they do so travel. It is exceedingly difficult to isolate pathogens from the air by the most refined technique. In tests with which I was concerned large barrack-rooms with very poor ventilation were tested. Nearly all the inhabitants were found to be carriers of meningococcus, but no meningococci were isolated from the air. For the greater part of a year I tested the air of crowded air-raid refuges without isolating haemolytic streptococci or pneumococci. The only haemolytic streptococci which I have isolated from the air came from the neighbourhood of patients with infected wounds. Such organisms have been isolated from scarlet-fever wards by many observers, but even the most crowded room occupied by healthy persons yields amazingly few pathogenic forms.

Flügge's original conception of droplet spread was criticized because the majority of droplets fall quickly to the ground. However, W. F. and M. W. Wells found that some were so minute—nuclei, as they named them—as to remain suspended for long periods. In this way infective agents might theoretically remain and build up in unventilated rooms. However, it appears certain that it is the organisms which fall to the ground or on to clothing or bedclothes which are the most important. Dust is undoubtedly rich in pathogenic bacteria and viruses. The varieties so isolated, even by the simplest technique, are most significant. Diphtheria bacilli can usually be found in fever hospital dust and tubercle bacilli in sanatoria, and the poliomyelitis virus has been identified in the dust of a room occupied by a case. I have rarely failed to isolate *Cl. tetani* and *Cl. welchii* from London dust, and infection with tetanus has been ascribed to air-borne spread. Streptococci are of particular importance, as they remain viable on blankets and clothing for a month or more. Small-pox virus remains infective on crusts for many years, and influenza virus in dust can survive for long periods. It is practically certain that under epidemic conditions plague and typhus, normally spread by insect vectors, can be spread by dust.

It is obvious, too, that organisms from the respiratory tract infect wounds; indeed, the early infections of wounds are largely from that source, the later infections being of faecal origin. Haemolytic streptococci, staphylococci, and diphtheria bacilli reach wounds from the respiratory tract either direct as droplets or indirectly on dust particles.

### General Principles of Control

It is necessary to do some clear thinking on the objectives and limitations of aerial disinfection. The provision of a pure water supply, though difficult, is possible and most desirable, since we can treat all the water drunk. But we cannot sterilize all the air breathed. The open air is always safe, but the maximum risk of air-borne infection, especially through droplets, is present where human beings are grossly crowded together as they are under modern transport conditions. Even if we could ensure safe air during the rest of a city worker's life he would be exposed at least twice a day to conditions where no known method of air sterilization could possibly operate. It was seriously suggested, at the outset of the recent war, that under epidemic conditions masks might be worn by all, and masks were in fact ready in store. But even if it were possible to induce people to wear them, would it really be beneficial? The medical history of the war was most instructive. Ventilation was very poor in the black-out. Air-raid refuges and tube stations were crowded, all the conditions for epidemics appeared to be present, and I was one of those

who formed a team to combat them. But apart from German measles, which did not appear to be related to overcrowding, no epidemics broke out. Again, the number of carriers of meningococci increased alarmingly, so that nearly all soldiers in certain barracks were affected; but the rise in the incidence of meningitis, though significant, was never a serious problem. Transports going to Egypt were grossly overcrowded: during the first week of the journey respiratory infection was universal, but the rest of the two-months journey was healthy. This was not true, however, of native troops from Africa, who suffered severely from pneumonia, chicken-pox, and meningitis. Is it not a fact that immunity from the common respiratory infections is closely related to constant exposure to infection? Herd immunity is a real thing; and we are all aware that a holiday from urban conditions is bought at the price of an acute "cold" on returning to town. If it is not possible to deal with crowded transport conditions, what merit is there in dealing with offices, places of amusement, restaurants, and churches?

There are two exceptions to this rule: the first, that times of pandemics with a new or rare infection deserve special consideration; the second, that children are analogous with the native troops in transports, as they represent a group with little or no acquired immunity and spend much of their time in homogeneous groups. There is a lot to be said in favour of air sterilization in schools, and still more in favour of keeping children away from crowded places. The cinema is probably a greater danger to child health than to child morals, and the special matinées for children are ideally devised to spread infections. Moreover, if we are again faced with a dangerous pandemic of influenza, doubtless every method of limiting the dose of infective agent would be logically employed. Whether any known method of air control would help is, in my opinion, doubtful.

We are left with hospitals, particularly with fever and children's hospitals. Here there is a clear case for control of air-borne infection. Sick and devitalized patients are grouped together, many of them with wounds actually or potentially infected, and all that we know of the bacteriology of air and dust teaches us that every known method of control is most desirable. In America this problem has long been seriously tackled; here in England in spite of much pioneer work we lag sadly.

### Methods

The methods available fall into several headings—control of droplet infection, ventilation, control of dust, and sterilization of air. Droplet infection must mainly be controlled by adequate masking: poorly designed masks merely collect organisms, which are then expelled in large doses. All nurses in infants' wards should be masked, and nurses with even minor respiratory infections should not remain on duty. The Spartan traditions of nursing are altogether bad. Since on speaking 300 organisms per word are emitted, operations should be silent. Sneezing expels 100,000 organisms per sneeze. The use of handkerchiefs is most desirable, but it would probably be far better if these were of paper, and used only once or twice. Proper ventilation is also essential. It is usually said that a poorly ventilated room has ten or less turnovers of air per hour: the best air-conditioning increases this to twenty-five turnovers. But in certain circumstances, as in operation theatres and surgical dressing-rooms, which at least for septic cases should be separate from main wards, a positive pressure of filtered air over the patient, as suggested and adopted by Bourdillon, is most effective, preventing banking-up of infected particles, and blowing away particles emitted by attendants. There is no substitute for good

entilation in the control of all forms of infection. In the hospital during the war an outbreak of cross-infection and casualties ceased only when the windows were blown in during an air-raid. But we cannot always rely on bombs.

Dust control, again, is a paramount concern. By air-borne infection we usually mean infection by contaminated dust. This has long been known, and the rounded corners of well-designed hospitals and operation theatres follow on this principle. It has been placed on a firm basis by the classic work of van den Ende and his colleagues, one of the most important contributions ever made to this subject. The majority of hospitals, however, still have dangerously polished floors, and blankets are only rarely washed; indeed, dark-coloured blankets are used to make the need for washing less obvious. Treatment of floors by spindle oil and of blankets by a special oiling method will control dust to a remarkable degree and entirely prevent the phenomenal rise of air bacteria during bed-making. It is true that tests of this method of preventing cross-infection have not always been conclusive; there are a great many other loop-holes in aseptic technique, as Spooner and others have shown. But, whatever other methods may eventually prove necessary in this matter, it is certain that dust control will remain a first essential. The removal of infected plaster casts from suppurating wounds is a further source of dangerous dust formation, and oil should be used along saw cuts.

#### Air Sterilization

We now approach a more vexed question, the sterilization of air by antiseptic mists and smokes and by ultra-violet light. At the outset it must be stressed that both these methods are effective only or at least mainly against droplets and droplet nuclei. This is often overlooked, for the greater part of the experimental work has been with organisms sprayed from fluid suspensions into the air. It is with this type of work that I have personally had most acquaintance, and I have satisfied myself that, while both methods are entirely effective against droplets, they break down with dust. Since dust is the most dangerous infecting agent their use is severely limited.

The method of antiseptic mist spraying dates from the time of Lister. Lister's phenolic mists were in fact not effective, since phenol used in his way is a poor aerial antiseptic. The last fair of Listerian technique is the cinema, where entirely useless spraying with odoriferous fluids is still practised. The originator of this technique on an efficient basis was Trillat, in France. Becholt developed the method in Germany, though neither author attracted much attention, and their names are rarely heard. In this country these antiseptics were developed largely through the laudable enterprise of commercial interests. There is an unreasonable and unfair prejudice in the medical profession against such activities, and it is only right to commemorate the work of firms such as the makers of "milton," the makers of "phantomyst," and the Portslade laboratories. The most important work is that of Twort and his colleagues at Portslade. Before and during the late war I had some personal contact with the method. Later it crossed the Atlantic, gaining, as is customary, much momentum and some amnesia in the transit. Of recent years most of the work on the subject, other than that of Twort and his colleagues, has been done there.

The facts are most fascinating and still largely unexplained. A limited number of antiseptics of low vapour pressure, when dissolved in low-vapour-pressure solvents and sprayed into the form of fine mists, can kill all droplet bacteria in five minutes or less. The amounts used are homocopathic in their values: 5 ml. of 1% sodium hypo-

chlorite will sterilize 1,000 cubic feet of air in less than five minutes, and less than 0.00025 g. of hexyl-resorcinol in propylene glycol will sterilize 1 cubic metre in a similar time. Robertson, in America, has claimed good results with propylene glycol alone; under the conditions of my experiments I did not find it valuable. Except in the possible case of sodium hypochlorite the question of volatilization—that is, solution of antiseptic in air—does not arise, for the amount of antiseptic sprayed is wildly outside the effective concentrations in fluids, and the effective agents are poorly volatile. I have suggested a species of balloon-barrage effect, through collision of particles, but mathematicians suggest that the rate of kill found is more rapid than collision would explain. It is possible that there may be attraction by an electric charge on the particles. Whatever the value of this method, from a bacteriological standpoint the results are of great interest.

More recently Twort has studied the effects of certain smokes (of which tobacco is not one) and has introduced heat volatilization of resorcinol, which greatly simplifies the technique.

All mists suffer from certain inevitable disadvantages. As mists are constantly being removed by ventilation, and also as all mists have a limited life, they must be constantly renewed; the better the ventilation the greater the volume of mist needed. Except with Twort's heat volatilization, this requires a constantly running mechanism, or at least one operating at frequent intervals. The occupants of rooms so treated are constantly breathing minute amounts of antiseptic. Some of these, such as sodium hypochlorite, are almost certainly harmless, and none have been shown to be harmful. Indeed, we probably inhale a great many phenolic substances every day without trouble. The most elaborate experiments on animals have failed to show any dangerous results. However, drugs and allergic individuals being what they are, sooner or later someone is sure to prove susceptible; with hypochlorites, also, some fading of textiles and corrosion of metals over a long period is possible. Most, though not all, have characteristic odours. Finally, although the volumes of antiseptic used are small, over long periods the expense would not be negligible.

Bacteria suspended in air can be as readily killed by ultra-violet light as by bactericidal mists. Indeed, from the point of view of speed and efficiency of kill there is little difference between the methods. The shortest period elapsing between the introduction of an organism and the production of practically sterile air was, in my experiments, about five minutes by both methods. The killing effect of light on bacteria has been known since 1899. The discovery that the bactericidal effect is mainly in the ultra-violet spectrum was due to the Klemperers in 1922. Here, again, transatlantic migration has proved a revitalizing process, and nearly all the work has been done in America. The names of Wells and Hart will always be closely associated with it.

Ultra-violet light with a wavelength of approximately 2,537 A.U. is used. It is produced by quartz low-pressure mercury discharge tubes provided with filters to control the rather objectionable ozone emission. There are no moving parts, upkeep is minimal, and the amount of electricity used insignificant.

The lamps may be used in many ways. For the sterilization of wards and living-rooms it is convenient for them to be above eye-level, and they must be mounted so that no rays are directed below this level. For operating theatres they have been directed on to the operation area, but the operators and attendants must wear goggles and all skin must be protected against burns. It has been suggested that there is a risk of adversely affecting viscera by exposure.

to the rays. I think that there are better methods of keeping bacteria out of wounds.

The Americans have been using ultra-violet rays for air sterilization for many years. It is a standard equipment in many schools and hospitals. Wells calculates that it is equivalent to 500 turnovers of air per hour, compared with the 25 turnovers by the best ventilation. In groups of schools the incidence of susceptibility to measles in an epidemic was from 9 to 15.5% in irradiated schools, and 55.3% and 51.8% in two unirradiated schools. Similar results have been found with chicken-pox. Experimentally, rabbits have been protected against air-borne tuberculosis. In my opinion ultra-violet light is the simplest and most efficient technique of this kind, and has no objectionable features if the eyes and skin are not irradiated.

Respiratory disorders, from tuberculosis and pneumonia, through sinusitis to the common cold, are far the most frequent of the diseases of mankind, and they are spread mainly through the air. The common infectious and virus diseases of childhood cause a high mortality and lifelong respiratory tract disease, and the air is again the commonest vehicle. Air-borne sepsis and cross-infection are common, particularly in wartime. There is still a tendency to laugh away the protagonists of the control of air-borne infection as faddists. I heard a gynaecologist quite recently become vastly humorous at the suggestion that a nurse with a cold was a menace. But there is far too much hospital-bred infection, and far too many "sterile" operations go wrong. I feel quite sure that the time will come when the methods of controlling air-borne sepsis discovered in Europe and developed in America will return fully fledged to roost in their parent country.

At a meeting of the North of England Obstetrical and Gynaecological Society held in Liverpool on July 4 Prof. T. N. A. JEFFCOATE described a simple method of replacing the retroverted uterus by manipulating it with a Hodge pessary. This method made the usual manual replacement unnecessary before inserting the pessary. With the patient in the left lateral position the Hodge pessary was inserted and allowed to take up its own position. The upper rim came to lie in the anterior fornix and the lower bar projected beyond the introitus. One finger was then inserted behind the lower bar, through the pessary, and in front of the upper rim, which was pushed against the anterior aspect of the cervix. The cervix was thus deflected backwards and the body began to rotate forwards. Ultimately the upper rim slipped past the cervix into the posterior fornix. By this time the retroversion was nearly always corrected but sometimes only partially, the uterus lying with its axis vertical. In such cases the upper end of the pessary was pushed firmly against the posterior vaginal wall and the posterior fornix repeatedly "stroked" backwards and slightly downwards with the pessary. At the same time the lower end of the pessary came to lie at a higher level. Thus the cervix was levered backwards and the fundus came forwards and the pessary was automatically left in its correct position. Prof. Jeffcoate also read a paper on pyrexia as a sign of endometriosis. He had found no reference to this sign in the literature but did not claim it as original. He said it had been established that temperature varied with the menstrual cycle, but the peak occurred premenstrually and the onset of the flow was characterized by a fall. In endometriosis he had several records of cases where a temperature up to 101° or 102° F. (38.3°–38.9° C.) appeared cyclically during menstruation and gradually disappeared one or two days after the flow ceased.

## BRITISH ANTI-LEWISITE

A Report on its Use and Therapeutic Value in Arsenical Intoxications, from the BAL Conference, Medical Research Council

BY

R. H. S. THOMPSON, D.M. (Secretary)

British anti-lewisite (BAL) is the name given to a compound, 2,3-dimercaptopropanol, discovered early in the war as a result of a planned research for the Ministry of Supply and developed as an antidote to the local and systemic damage caused by contamination of the skin or eyes with arsenical vesicant gases.

In the pure state it is a colourless oil, readily soluble in fat solvents, and soluble to the extent of about 6% in water. During 1941–2 its value in counteracting the effects produced by contamination with lewisite was exhaustively studied, and it was finally adopted officially as a suitable agent for the treatment of the effects of lewisite and the other arsenical vesicants. Its efficacy as an arsenical antidote and its power to reverse the tissue damage caused by arsenicals depend on its ability to form relatively stable ring compounds with arsenoxides, thereby diminishing the reaction of the arsenical with the tissues and increasing its urinary excretion from the system:

A review of the original work with lewisite has already appeared (Peters, Stocken, and Thompson, 1945), together with an account of the early developments of this work in the U.S.A. (Waters and Stock, 1945).

The application of BAL to the treatment of dermatitis and other complications arising in the course of arsenotherapy has also been extensively studied both in this country and in the U.S.A. The present short report summarizes the findings of a clinical trial of the therapeutic value of the compound carried out recently under the auspices of the Medical Research Council, a full account of which will shortly be published (Carleton, Peters, and Thompson: in the press).

## Trial in Arsenical Dermatitis

The trial was based on the results obtained in 44 cases of arsenical dermatitis collected with the assistance of the Service Departments and the Ministry of Health. To facilitate the interpretation of any effects noted, the cases were selected so that the dermatitis was in each instance severe and widespread, 41 of them being of the acute exfoliative type.

Treatment was carried out by the clinicians in charge of the cases according to a scheme prepared by the BAL Conference, which was intended for initial guidance as to dosage. The ampoules of BAL used in this work were prepared by a modification of the method described by Eagle in the U.S.A., and contained 5% BAL in arachis oil

and benzyl benzoate; they were nitrogen-filled, and were sterilized by heating for one hour at 170° C.

The BAL was given by deep intramuscular injection into the thigh or gluteal region. In the hope of maintaining a concentration of the drug the following course of injections for adults of average weight was given in most cases: First day—4 injections of 2 ml. 5% BAL at 4-hourly intervals; second, third, and fourth days—2 ml. twice daily; fifth and sixth days—2 ml. daily. Where possible other local treatment of the affected skin was withheld.

From the reports received from the clinicians who co-operated in this trial it has been concluded that BAL therapy is of definite value in the treatment of this condition. Thirty-one of the 44 cases studied (70%) were benefited by the treatment, 23 of them (52%) strikingly so. The mean duration from the first injection of BAL to the time when healing was complete or nearly complete was 21 days. The earliest sign of response to treatment was in many cases a marked subsidence of the oedema present in the skin. In several instances clinical evidence of relapse was seen shortly after the end of the course of BAL therapy. In every case, however, this responded satisfactorily to a further short course of injections.

The outcome of this trial is in agreement with the results obtained elsewhere. The earliest use of BAL in the treatment of widespread arsenical lesions in man was in 7 cases of dermatitis (Longcope, Luetscher, Wintrobe, and Jäger, 1946) occurring in workers exposed to diphenylamine chlorarsine (phenarsazine chloride). These workers have also described 15 cases of generalized exfoliative dermatitis following the use of antisyphilitic arsenical drugs, and have stated that symptomatic and objective improvement regularly followed the administration of BAL. In this country Carleton *et al.* (1946), in an earlier series of 30 cases, have reported a beneficial effect in approximately 50% of cases.

Although favourable reports on the use of BAL in cases of arsenical encephalopathy and granulocytopenia have appeared in America (Report of the Council on Pharmacy and Chemistry of the American Medical Association, 1946; Eagle and Magnuson, 1946), we have not been able to study a sufficient number of cases of either of these conditions in this country to warrant a conclusion.

Clinical reports on the use of BAL in acute mercury poisoning (Longcope and Luetscher, 1946) and in gold intoxication (Cohen, Goldman, and Dubbs, 1947; Ragan and Boots, 1947; Lockie, Norcross, and George, 1947) have also been published, and the results obtained with these metals have been favourable. In the case of mercury 22 of the 23 patients studied recovered completely, although the amounts of mercury swallowed varied from 0.5 to 20 g., while 9 of the 10 cases of gold dermatitis described appear to have shown a prompt response to therapy. Work with lead, bismuth, and other metals has not yet progressed beyond the stage of animal experimentation.

### Toxicity of BAL

As regards toxicity, the minimal dose given by intramuscular injection to man which causes toxic reactions lies between 3 and 5 mg./kg. Single doses of up to 8 mg./kg. have been given to normal subjects, and even at this level the toxic manifestations are completely reversible, lasting only a few hours. Apart from subjective phenomena, lacrimation, salivation, vomiting, and an elevation of both systolic and diastolic pressure occurred with these higher doses (Sulzberger, Baer, and Kanof, 1946; Modell, Gold, and McKeen Cattell, 1946). It should be pointed out that the therapeutic dose used in this country has been only about 1.5 mg./kg.; in America, on the other hand, a 10% solution of BAL has been used, and 6 doses at 4-hourly

intervals of 3 mg./kg. have been given on the first day in severe cases (Eagle, 1946). In the treatment of acute mercury poisoning initial doses of up to 7 mg./kg. have been employed.

Though no evidence has been obtained of any increase in toxicity when BAL is injected into animals with experimentally induced renal damage, or of renal irritation in any of the cases in this series, increased toxic effects were present in animals with hepatic damage, which suggests that care should be exercised in the administration of BAL to patients with impaired liver function (Cameron, Burgess, and Trenwith, 1947). It should be added that BAL is not generally indicated in the treatment of post-arsphenamine hepatitis, the immediate cause of which appears to be infective in most cases (Salaman, King, Williams, and Nicol, 1944). Local abscesses have developed at the injection sites in a number of cases treated in this country. These may have been due to the septic condition of the skin in patients with exfoliative dermatitis of some standing, who are, in any case, prone to intercurrent infections of all kinds. This complication is probably preventable by the administration of BAL early in the course of the condition. A possible contributory factor is leakage of the substance into the subcutaneous tissue, which may be prevented by giving all the injections deep into the muscles. The abscesses, though troublesome, have healed satisfactorily with simple treatment, and do not, in our opinion, constitute a contraindication to the use of BAL in such cases.

### Conclusion

Up to the present time BAL has been manufactured by the Ministry of Supply, and in order that its therapeutic value could be firmly assessed distribution has been effected only through the Medical Research Council. It is considered that the value of the compound has now been established, and arrangements are being made by the Ministry of Supply for the preparation and issue of ampoules of BAL by firms in a position to exercise adequate biological control.

We would like to express our thanks to Miss F. B. Uffemann, Ministry of Supply, and to the various clinicians who have co-operated in this trial, and also to Messrs. Boots Pure Drug Co., Ltd., and Messrs. Burroughs Wellcome and Co., Ltd., for the dispensing of the material used.

## MANIC STATES IN THE FAR EAST

## MANIC STATES IN THE FAR EAST\*

BY

R. F. TREDGOLD, M.D., D.P.M.

Formerly Lieut.-Col., R.A.M.C., Adviser in Psychiatry, S.E.A.C.

Shortly after the Japanese capitulation there were observed in South-East Asia a number of cases of interest in several ways: their cause was obscure; their symptoms were elation, overactivity, and fever; their distribution was mostly in young British officers; and, however acute the symptoms, the prognosis was good.

The first appearance of these cases was dramatic. In August, 1945, preparations for the reoccupation of Malaya had been made, and at the last moment the Japanese capitulated. The blow thus, so to speak, fell upon air. A few weeks later four British officers were admitted within a period of 12 days to the psychiatric centre serving the corps concerned. Between the landings and the end of this period no other cases of psychosis—British, Indian, or Gurkha—had been reported in this corps.

Col. T. A. Ratcliffe and Majors J. D. Frazier, D. T. Bardon, and A. A. Martin. Others may have occurred in this theatre at the time, but they cannot have been many, for the psychiatrists—to whom they necessarily came—had been asked to notify me of any cases.

## Symptoms

The presenting symptoms were very similar. The patients were overactive, mentally and physically, easily excited to further activity, and exceedingly garrulous; they were elated and had some exaggerated ideas of their own importance, which at times amounted to mild delusions of grandeur, but which were always within the bounds of possibility and not fantastic. In a few cases religious ideas with a vague symbolic content were described; in a few there were ideas of reference and of persecution, and one had auditory hallucinations.

Although it was obvious that their judgment was impaired, most patients were capable of holding moderately logical conversations and showed little loss of comprehension. Only three exhibited flights of ideas, though most were rather easily distracted. The grasp of his surround-

As a result of this experience, investigations were made in other areas and further cases were found: 11 in Singapore (these occurred in the island itself or had been sent from South Malaya, Java, or Sumatra); others were seen in Bangkok and Rangoon, or came from H.M. ships at sea. In all, records of 23 cases have been collected (Table I), of which I saw 16. Details of the remainder (in several different areas) were kindly supplied by Lieut.

ings shown by one patient—a senior officer—was such that he had put forward a detailed scheme of operations for some training which was accepted by his superiors: its inconsistencies were not discovered till it was actually put into practice. This was, however, unusual, for in the remainder overactivity and distractibility were enough to send them off duty. Recognition of time and place was generally accurate, but mistakes were sometimes made in identifying passers-by with old acquaintances. Memory for recent events was on the whole good. It is regrettable

\* A portion of a thesis accepted for the degree of M.D. at the University of Cambridge.

that local difficulties as well as the clinical states prevented a more systematic investigation of attention, memory, and comprehension.

When first seen many patients were aggressive, abusive, and sometimes very violent. This symptom disappeared rapidly when skilled cure could be provided; it is probable that it was not so much a primary symptom as a secondary result of the opposition, restraint, and, unfortunately, antagonism occasionally provoked by the patient's behaviour. It is to be emphasized that the most striking symptoms were overactivity and change in mood, and not a disorder of comprehension.

Investigation into the onset of the condition usually revealed a change in behaviour over the last two or three days—in two cases, ten days. Generally this change consisted of overactivity and elation, as described above, and it increased gradually. But several patients had, on the contrary, been morbidly depressed before their excitement began, and two had had feelings of inadequacy and guilt—for which each had had some real cause. One of these two had sought refuge in a day's heavy drinking. One man (Case 18) had been so aggressive and insubordinate as to have been put on 61 charges by an apparently meticulous C.O. in the ten days before admission. In some cases there were records of low fever of 99° to 100° F. (37.2° to 37.8° C.) before admission, and several patients said they had felt feverish for a few days and had been out of sorts and sleeping badly. No focus of infection or any sign of physical abnormality was discovered in any patient except the one whose temperature rose to 102° F. (38.9° C.); he showed an erythematous rash. Blood cultures, blood counts, and examinations for malaria parasites were all negative. Most cases were very resistant to sedatives, becoming less restive only on heavy doses. Little change was seen in their behaviour for a week or so, and careful nursing and supervision were essential.

### Previous History

Naturally, the earlier history of these patients was generally dependent on their unsupported statements obtained after recovery; but most showed a singular lack of previous psychological disorder. Only two had had any trouble—one had had a schizoid attack a year before, which cleared up in a few months, and the other had apparently had a hysterical amnesia. Moreover, the Service records of nearly all were good. They were occupying responsible positions and enjoyed a good reputation (among superiors and subordinates alike) for conscientiousness and hard work.

Investigation of the circumstances before the onset showed that fourteen cases had been definitely exposed to increased mental work and increased responsibility for a few months before V.J. Day.

Four of the first five officers had been employed for several months on staff work, involving much planning, minute attention to detail, and severe responsibility for the lives of others; and it is significant that all four were reported to have expressed considerable misgivings about the success of a landing against opposition (whether this was at all justified by the facts as they saw them or was itself a symptom of illness it seems impossible to say). Four other cases had considerable anxiety over domestic problems—two were simply home-sick, and two found themselves "browned off" at lack of work. No mental stress was elicited in the remainder, but two of them had had a history of some infection a few weeks before.

The rank incidence is of great interest: seventeen patients were officers and six were "other ranks." Moreover, two of the latter were holding extremely responsible

jobs. One patient, an officer, was an Indian. The ages ranged from 19 to 37 years, but only one was over 30.

### Course of the Illness

During treatment several patients became hypochondriacal and expressed anxiety over minor complaints; others showed considerable anxiety over their future careers. This was not due to realization of the seriousness of their past illness, for few had a full insight into the abnormality of their past behaviour, and several had a complete or partial amnesia for the acute period. When it was partial they remembered their surroundings in hospital but not their own aggressiveness, though a few admitted they might have been "a bit unreasonable." Others had no memory of doctors who had seen them in their acute phase. In two months from the onset seven had made a complete clinical recovery, and thirteen were still improving.

In all these either electric convulsion or insulin treatment had been given. Two had shown improvement described as "recovery," but then relapsed. It is of interest to note that these two were those with a record of previous psychological disorder—one, with a previous schizoid episode, developed a paranoid schizophrenic state which persisted; the other, with a hysterical amnesia in his record, became temporarily confused and aggressive during his voyage home.

Finally, one patient died. A few days after admission with typical symptoms his temperature rose to 101.6° F. (38.7° C.) and he became stuporose; the temperature dropped just before death a week later. A blood count showed 18,000 white cells per c.mm., but no physical abnormality was found clinically and none at necropsy except cerebral oedema and many small haemorrhages. This was one of the cases with a depressive onset.

A full follow-up of all cases after a year is naturally not available, since most were evacuated from South-East Asia to India, and I saw only a few. The details were obtained from Col. R. J. Rosie and Lieut.-Col. A. J. Galbraith, to whom I am indebted.

### Rates of Psychosis

The importance of these cases may be thrown into relief if the general rate of psychosis in this period is compared with a sample of cases evacuated from India and Burma earlier in the year (Table II). It will be seen (a) that a

TABLE II.—*Distribution of Types of Psychosis*

Source	Date	Schizophrenics	Manics	Depressives	Others	Total	% of these Psychoses to all Psychiatric Cases
All evacuations from India and Burma	Jan.-July, 1945	64	17	29	11	121	24.2
All evacuations from S.E. Asia	Oct., 1945-Jan., 1946	24	11	1	5	41	44.1
	Feb.-June, 1946	14	1	5	—	20	43.8

much greater percentage of psychoses occurred in cases evacuated from South-East Asia between October, 1945, and June, 1946—unfortunately figures are not available for August and September, 1945, here; (b) that this rise was in part due to an increase of schizophrenics, which persisted till June, and in part to an increase in manics, which was evident only in the winter months.

The grouping by rank (Table III) is of interest. The disproportionate number of officers in the manic states is obvious.

TABLE III.—*Distribution of Psychoses by Rank*

	Feb.-June, 1946	—	1	—	14

### Review of Literature

No exactly similar series has been found in the literature surveyed; but various writers draw attention to significant points.

**Incidence of Psychosis.**—A higher rate of psychosis is generally recognized to prevail in the East. From the official figures for admissions to hospital the ratio of psychoses to psychiatric cases can be obtained. In England, between 1942 and 1945, this was as follows:

	All Ranks	Officers	Other Ranks
April, 1942–March, 1943 ..	25.3%	30.1%	15.0%
April, 1943–March, 1944 ..	26.5%	45.8%	25.4%
April–December, 1944 ..	16.3%	19.8%	16.2%
July and August, 1945 ..	20.3%	21.0%	20.2%

(*Bulletin of Army Hygiene*, April, September, and October, 1945.)

For periods in the Middle East, the figures for British troops, unfortunately not separated into officers and other ranks, were:

Oct.–Dec., 1943 ..	19.0%	July–Dec., 1944 ..	23.0%
Jan.–June, 1944 ..	31.3%	Jan.–March, 1945 ..	28.1%

(*Bulletin of Army Hygiene*, October, 1945.)

These figures support the theory that there is generally a higher proportion of psychosis in the East than in England, and also show clearly the higher rate among officers. No explanation of either point is given by the compilers of these figures.

**Distribution of Psychosis.**—There are various views on how the total of psychotic cases is made up by the various syndromes. Craigie (1944), in the Middle East, gave the ratio of schizophrenics to manic-depressives as over 3:1. Later, James (1945) considered that among 530 psychotics evacuated it was over 4:1.

### Aetiology: Physical Factors

It is generally accepted that certain psychoses are directly due to physical causes; confusional states, for instance, may be caused by toxic processes. As the latter are commoner in the East it is possible that this is one reason for the higher incidence of psychosis there. Stungo (1946) suggests this, and also mentions the effects of dehydration.

Malaria was, of course, one of the commonest diseases met with in the East, and it often affected the mind. Its effects were also diverse—so much so that official directives were issued to doctors in the East recommending anti-malarial treatment in all febrile mental syndromes. On the other hand, Merrill (1945) warned us that an aggressive psychopath might seek refuge in the word "malaria" and demand appropriate treatment, when his condition was purely a psychiatric one.

Mepacrine (atebrin) has also been blamed as a cause of psychosis. The evidence for any ill effect from a daily preventive tablet does not seem strong; it would in any case presuppose a rare idiosyncrasy. Larger doses given in treatment of malaria are obviously more likely to be dangerous and need careful consideration.

The largest series of cases of malaria recorded is that of 7,604 treated by Gaskill and Fitzhugh (1944); 35 of

these developed psychoses, which were of two main kinds—confusional states, and states of excitement with delusions. But these authors admit that there is no convincing evidence of a direct effect of mepacrine, or even of malaria.

From Burma several other cases have been reported in which confusion, excitement, and hallucinations followed the use of mepacrine; these improved on its withdrawal but recurred on its renewal (unpublished communications from T. A. Ratcliffe and Kirpal Singh). As these authors admit very readily, however, it is impossible to be sure this was not due to the fluctuations of a psychosis; in fact, in one case an overdose of mepacrine was symptomatic of an incipient psychotic episode. Soysa (1945), in an unpublished communication, reported ten cases which showed toxic effects from mepacrine, but these were drawn from 550 patients treated in Ceylon in two years. Eight of the ten were typical hypomanic attacks and two manic. All recovered when the drug was withdrawn, but one relapsed when it was given again. The responsibility of mepacrine here seems more likely, but an account of the patients' previous personalities and of the psychological stresses they underwent would be of interest.

There are thus, obviously, factors whose full influence is not yet understood, and the exact relation of physical agents to these psychoses is not yet clear.

### Mental Factors

These may be grouped under the headings of frustration, change of tempo, and constitutional.

**Frustration** is a term commonly used to describe a feeling of wasted ability, which may develop into an anxiety state either with depressive features (Gillespie, 1942) or with great tension, irritability, restlessness, insomnia, and a sense of internal unrest—in which state the sufferer is capable of doing considerable work, but at great cost to himself and his subordinates. This has been described elsewhere, as it occurs in base areas overseas (Tredgold, Heffernan, Kelly, and Leigh, 1946), and in the connexion MacCurdy's account (1945) of what is inevitable in departmentalism shows how the lack of aggressive outlet causes irritation to be vented on subordinates, so that a vicious spiral develops. The desire for scapegoats is significant; the next higher formation "they" are always blamed, so that G.H.Q. the apex, invariably becomes a byword.

**Change of Tempo.**—A more direct effect of the actual war and its pace is described by Curran and Garmany (1944) under the term "change of tempo." They give a series of cases of anxiety which developed in sailors just ashore on leave or alternatively, in men admitted to hospital for some minor complaint, and consider that this might be due to the persistence ashore of the increased responsiveness developed by tension at sea.

**Constitutional.**—The importance of constitutional factors in psychoses has been widely accepted, and MacCurdy (1929) claimed that they were always discoverable even in patients whose relatives had not noticed them.

Further, specific types have been regarded as particularly liable to mania—the rigid individual (Freud, 1912), and the over-conscientious obsessional type who develops a sense of injury which prevents him from resting and has on occasion developed a typical manic-depressive cycle (Culpin, 1931), especially if his personality structure is characterized by self-centredness, lack of sociability, and lack of affection (Wittkower and Spillane, 1940).

### Discussion

The cause of such conditions is generally considered to be physical, and blame has been laid on malaria and mepacrine. Both are no doubt often responsible for states of excitement. The rather similar cases quoted by Soysa, for instance, were held to be due to excessive mepacrine, whereas Stungo's cases labelled as "toxic" showed actual

excitement, confusion, and fever, and several died in a way that resembled the fatal case here recorded. In this series, however, there was no record of overdosage of any drug or of the confusion reported in malaria, and no parasites were found; moreover, it is difficult to see any reason why malaria or overdosage of mepacrine should increase suddenly after V.J. Day.

On the other hand, there were mental factors which must have played a part. There was a very sudden and acute change in the tempo of work with a sudden relief of tension. This must have affected most strongly the over-conscientious responsible type of staff officer who had been employed in circumstances (the planning of a major operation) calculated to increase these obsessional tendencies and anxiety. This type formed the majority of the patients.

The restless state which appears in frustration has been described as an underlying unrest which the individual tries to stifle. It is not a great step to the symptoms of mania—where unrest has become overactivity and the attempt to stifle guilt or unworthiness has been oversuccessful and so crystallized out as a delusion of grandeur and elation.

The temperature of these cases suggests a toxic process, but full examination by physicians as well as psychiatrists failed to find any. Perhaps the fever was the result of the overactivity, not its cause. Much attention has been paid to physical conditions because these cases are commoner in the East and commoner in war, where exposure to physical illness is greater. But there are simple explanations, in psychological terms, of both these points. War produces a sense of urgency which is particularly felt by the overconscientious obsessional type. The latter's relaxations, too, are restricted, for he is often home-sick, tries to lose himself in his work, and will not take leave—where, as he says, he has nothing to do but brood and get more home-sick. In forward areas there is a physical outlet combined with the sense of work well done and a feeling of comradeship engendered by danger: relaxation is easier after action. In staff work and base areas there is less sense of achievement. The East thus exerts as much psychological effect—in separation from home and incompatible surroundings—as physical strain.

### Summary

A series of 23 cases showing elation, overactivity, and fever occurred in South-East Asia in the months following the Japanese surrender.

The patients were mostly young officers (British) without a history of previous breakdown. The prognosis was good.

Records of psychosis in the East are reviewed.

A discussion of the possible causes leads to the conclusion that they were mental rather than physical, and are thought to be the sudden release of tension and the consequent change in the tempo of work.

## HOMOSEXUAL OFFENCES AND THEIR RELATION TO PSYCHOTHERAPY\*

BY

F. H. TAYLOR, O.B.E., M.D., D.P.H., D.P.M.

Medical Officer, H.M. Prison, Brixton

During 1946 there was considerable correspondence in the columns of the *British Medical Journal* on the subject of homosexuality, particularly concerning the forensic aspect. It was evident that there was a wide divergence of opinion, and in addition some of the correspondents seemed unaware of the extent to which homosexual offences occurred and of the extent of treatment carried out before the offence was committed. It was in fact evident that some regarded the commission of a homosexual offence as a *sine qua non* that the offender was a homosexual and that psychotherapy in some form was indicated. All cases charged with homosexual offences and received into H.M. Prison, Brixton, on remand or committed for trial are investigated as a routine; it was decided, therefore, to analyse those received during the year 1946 in order to ascertain whether the above-mentioned views were justified.

During that year 96 persons were received into the prison charged with homosexual offences; of these 52 (54.2%) were accompanied with a request from the magistrates for a report as to the state of mind of the accused, whereas the remaining 44 were examined owing to the nature of the charge. The total number of remand and trial prisoners received during the year was 5,023, so that the percentage of those charged with homosexual offences was 1.91. For comparison the number of cases charged with heterosexual offences was 198, of which 142 (71.7%) were sent for a report as to the accused's state of mind. Homosexual offences can be divided into four main groups—namely, indecent assaults on boys under the age of 16 years, importuning, buggery, and gross indecency. Of the 96 cases under consideration 39 were charged with indecent assaults on boys, 24 with importuning, 17 with gross indecency, and 16 with buggery. It is interesting at this point to consider the extent to which magistrates asked for reports on the mental state of the prisoner in respect of each of these groups of offences. In the cases of indecent assault reports were requested in 25 (64%), in cases of importuning in 20 (83%), in cases of gross indecency in 5 (29%), and in cases of buggery in 2 (12.5%). It is obvious that the law has much less consideration for medical opinion in cases of gross indecency and buggery than in the other two offences. Of the 96 cases, 57 involved offences against boys (including of course all the indecent assaults) and 39 involved offences against men.

The cases are classified into four groups. Individuals who on investigation were found to have heterosexual tendencies and in whom the homosexual offence was in the nature of a substitution for the normal heterosexual act are classified as "pseudo-homosexuals." The second group consists of the "bisexuals," individuals in whom strong heterosexual as well as strong homosexual tendencies were obvious. Thirdly, there were the "prostitutes," who are individuals who would have fallen into the pseudo-homosexual group but were characterized by the fact that the homosexual acts were carried out for gain. It is of interest that all these cases had previous convictions for the same offence. Finally, there is the group of the "true inverts" which numbered only 13, or 13.5% of the total series.

\* Published by permission of H.M. Prison Commissioners, though it does not necessarily express their views.

Classification of the cases into these groups is shown in Table I.

TABLE I.—Classification

	Indecent Assault	Importuning	Gross Indecency	Buggery	Total
Pseudo-homosexuals	34	13	11	8	66
Bisexuals ..	5	1	2	4	12
Prostitutes ..	0	2	1	2	5
True inverts ..	0	8	3	2	13
Total ..	39	24	17	16	96

*Date of Offence.*—It has been stated that sexual activity and sexual offences reach a peak in the spring. Walker and Strauss (1939) suggest that this also holds good for homosexual offences. A glance at Table II shows that in 1946 at any rate this was not the case. On the contrary there was a general rise to a peak in September.

TABLE II.—Date of the Offences

Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
3	5	7	8	6	8	9	5	15	9	11	10	96

*Age.*—Criminal statistics for some time have shown that the greatest incidence of adult crime occurs in the age group 21–29 years and that there is a steadily decreasing incidence in the higher age groups. Brixton Prison receives only men aged 23 years and over, and the lowest age group is therefore 23–29. Table III shows that the incidence of homosexual offences was slightly greater in the decade 30–39. For comparison, figures extracted from the Reports of the Commissioners of Prisons and Directors of Convict Prisons for the years 1939–41 and 1942–3 are included. These confirm my own findings. The figures for males convicted for all indictable offences in the years 1939–43 show the greatest incidence in the age group 21–29 in every year. The figures for males convicted of unnatural offences for the same years show a higher incidence in the age group 30–39 years; in 1941 and 1943 an even higher incidence was shown in the age groups 40–49 years.

1942 ..	61	83	75	36	24
1943 ..	66	100	116	48	19

*Previous Convictions.*—Of the 96 cases under review 55 had no previous convictions of any kind, 19 had one, 10 had two, and 12 had three or more. Of these, however, only 22 had been convicted for a homosexual offence. The figures are shown in detail in Table IV; they are comparable with figures extracted from the reports of the Prison Commissioners mentioned above.

### The Pseudo-homosexual Group

As has been stated there were 66 prisoners falling into this group. Of these, 34 were found to have some form of mental abnormality. Two were insane, six were certifiable under the Mental Deficiency Acts, and sixteen had had mental treatment in one form or another. The various disorders were as follows: post-concussive syndrome, 1 feeble-minded, 2; imbeciles, 4; epileptics, 3; personality defects, 12; schizophrenia (insane), 1; senile dementia (insane), 1; senile dementia (non-certifiable), 1; anxiety states, 4; dull and backward, 5.

One very interesting point emerged from a study of the group. The magistrates asked for a report in 39 of the 66 cases, and of the 39 no fewer than 29 are to be found in the above-mentioned cases. This suggests that the magistrates are very much on the alert for abnormalities; the "missed" only an epileptic, two anxiety states, a dull and backward case, and that of non-certifiable senile dementia. The following brief histories will show the type of case falling into this group.

*Case 25.*—Aged 43 years. Indecent assault on two small boys on repeated occasions. Two previous convictions for importuning. He was born in England, but spent his childhood up to the age of 8 years in Poland and then attended a elementary school until 14. He had never held any employment for long and was boarded Grade IV for the Forces. In 1933 he was charged with importuning and his mental age was found to be 8½ years. He was certified as a feeble-minded person and sent to a mental deficiency colony, but was discharged in 1945, when his mental age was considered to be 9 years. He showed no improvement; his general knowledge was defective, he was unable to reason, had no insight, and was considered to be still certifiable. The local M.D. authorities agreed with this decision and accepted him back.

*Case 44.*—Aged 31 years. Indecent assault on boys; on previous conviction for stealing. He had exposed himself to two boys aged about 7 years and had placed his hand on the private parts. No attempt was made at masturbation, and the offence occurred in daylight. He admitted similar offence over a period of a year and also indecent assaults on little girls. He had served in the R.A.F., but was invalided with "neurasthenia." He was educated at a grammar school, and had been a clerk since leaving school. He admitted frequent masturbation and heterosexual intercourse; he still desired the latter but said "he never had time nowadays." The police on searching his room found copious notes made by him on subjects of a heterosexual nature which at first appeared to be nonsensical as well as portraits of nude females cut from a well-known magazine. These he used as a sexual object during masturbation. In addition a small brass bust was found which he used to sit upon while masturbating. He did this, he stated, because he had a drawing sensation in his testicles and he used the brass bust to support them. He explained the writings as a form of shorthand which he had devised and gave an explanation of what he had written that was fanciful and bizarre in the extreme.

He expressed strong antipathy to the "present constitution," by which he said he meant "the upper classes, royalty, financiers, and absentee landlords—the non-productive classes." He was introverted and had faulty insight, but he was not considered to be certifiable under the Lunacy Act. Treatment as a voluntary patient was recommended.

**Case 47.**—Aged 32 years. Indecent assault on a boy aged 11; 10 previous convictions. He was a Civil Servant, living beyond his means, but he had a record of being an intelligent and good worker. He had assaulted a small boy whom he had caught stealing fruit in his garden. He ordered the boy to drop his trousers with a view to thrashing him, but altered his mind, and, having played with the boy's privates, he persuaded the boy to play with his. He stated that this was the only occasion on which he had committed a homosexual assault. On investigation an interesting domestic tangle was unearthed. It appeared that his wife had flirted with a male friend of his after a cocktail party. This had made the prisoner jealous, and he had upbraided her and told her to go and sleep with the young man, who happened to be staying with them at the time. Mainly to frighten him, the wife went to the friend's room, entered the same bed and there was some love play though no actual intercourse. The prisoner was distraught with anxiety after this event and became impotent with his wife, though he was able to masturbate. Financial worries added to his anxiety, and he arranged to see a psychiatrist. Before he could keep the appointment he was arrested. The above story, amazing as it may seem, was confirmed by the wife at an interview. She was a dramatic, shallow creature who had broadcast the story of the "incident" to her neighbours, apparently under the impression that it sounded romantic. This man was eventually bound over and attended a psychological clinic, as recommended in my report to the court. The probation officer reported four months later that he was doing very well indeed and there was complete domestic reconciliation.

**Case 90.**—Aged 29 years. Gross indecency; one previous conviction for same offence seven years previously. This case is included because of the prisoner's physical condition. He was effeminate in appearance, with the female type of secondary sex characteristics and an aesthetic artistic temperament. He had served in the Army and was at Dunkirk; he was eventually invalided for "nerves." He had regular heterosexual intercourse, usually with prostitutes; he denied homosexual intercourse or desire. On the night of the offence he was awaiting a male friend and had had a good deal to drink. He went to a public urinal and a man in the next cubicle spoke to him and exposed his penis, which was erect. Mutual masturbation followed and the act was interrupted by a plain-clothes constable. There can be no doubt that the feminine appearance and mannerisms of the prisoner had attracted the other man.

### The Bisexual Group

This group consisted of 12 individuals, and the distribution of offences is shown in Table I. Four had already had psychotherapy, with very little effect; four were recommended for treatment to the court; and four were considered unsuitable. In all cases there were strong homosexual and heterosexual tendencies. It is not agreed that the bisexual is more or less homosexual and does not obtain proper pleasure from intercourse with members of either sex as alleged by Allen (1940). In many of the present group almost complete heterosexual satisfaction was achieved, in some cases in homosexual intercourse as well. It was noted, however, that there was a tendency to commit the sexual act in an unnatural way. This was not so much by way of a perversion in the psychiatric sense, but rather an indication of sheer depravity. The following case illustrates this very well.

**Case 63.**—Aged 41 years. Indecent assault on a boy aged 11. Three previous convictions, for indecent assaults on boys (2) and sodomy (1). He was a dullard, with a matrix S.G.5. His general knowledge was limited and he could read and write very little. He had served in the Forces, but was discharged as medically unfit, presumably because of his backwardness.

He was married, but separated from his wife because she had been unfaithful with an American soldier. He was accused of interfering with a small boy sitting next to him in the cinema and encouraging the boy to rub his penis. He had masturbated from his school-days and first had sexual intercourse at the age of 15 years with a schoolgirl aged 16. Before his marriage he had a voracious sexual appetite and had frequent intercourse with women. There were also incidents with small boys, and he admitted peno-rectal intercourse. He had developed a taste for fellatio and cunnilingus, and there was a suggestion of sodomy with women. In France he had enjoyed watching "exhibitions" and had performed nauseating variations of the sexual act with French prostitutes.

### The Prostitute Group

These five persons had deliberately gone out with the intention of making money by offering themselves to men. In three cases they had attracted their victim and were arrested in the act; the other two were apprehended at the stage of importuning. The following case history is typical.

**Case 73.**—Aged 59 years. Importuning; one previous conviction for same offence; had had psychological treatment at a London hospital. He held a good position in a multiple boot firm, but was in financial difficulties at the time of the offence. He was a single man and had had intercourse with numbers of women. He also had homosexual experiences while in the Army during the 1914-18 war, but these had never gone further than mutual masturbation and there had been none since. Bearing his 1914-18 experiences in mind, he decided he might make money by soliciting men to mutual masturbation. He was apprehended while doing this in a public lavatory at Paddington Station. The man was unstable and showed evidence of a mild anxiety state with superadded compulsive-obsessive traits characterized by claustrophobia.

### The True Inverts

As has been indicated earlier, it is this group which is of most interest to us and which has been the subject of so much correspondence. There were 13 cases, of which no fewer than eight were importuning; there were three cases of gross indecency and two of buggery. East and Hubert (1939) mention that a large proportion of such cases have other forms of perverse sexual activity; four of these cases showed obvious perversions. Allen (1940) suggests that fetishes in homosexuals are rare, but this is not confirmed. Though the fetish was not always concrete, indulgence in imagery involving masculine articles of clothing or essentially masculine features such as beards and moustaches was common. Of the 13 cases only one was interested in boys; the other 12 were attracted to men, and had never been at all interested in boys. The commonest single environmental factor was seduction in early youth or childhood, with employment in hotels or public-houses as the second most frequent. In only one instance was a history given of emotional suffering caused by a woman. Androgynous physique was present in six cases, which is probably a higher proportion than usual. The part played by the homosexual was rather more definite than is usually accepted; it was found that the individual preferences were as follows: always passive, 5; always active, 2; either active or passive, 3; mutual masturbation only, 3. Of the five preferring the passive role, three were androgynous and two were of masculine build. Of the two active men one was quite effeminate in appearance. Perversions were much more evident in those preferring the passive role; fellatio was admitted by four men.

East and Hubert (1939) state that in an investigation of a series of cases they found no evidence which led them to attach any weight to the homosexual fantasy. Careful questioning was made as to the fantasy, if any, experienced during nocturnal emissions. The result was somewhat startling. Eleven of the men had a definitely homosexual

fantasy; this sometimes amounted to no more than a dream of self-masturbation, but in some instances they experienced in their dream a complete homosexual act, usually passive, but sometimes active. One man always dreamed of committing mutual masturbation with a man very similar in appearance to himself.

Bleuler (1924) states that homosexual love shows the same signs as heterosexual love but also particularly something strikingly ecstatic and exalted. Two of the cases (Nos. 85 and 91) which are given below brought out this point with great emphasis. Emotional conflicts were present in seven of the men. One showed a simple anxiety at his condition; five had a sense of guilt, very strong in three cases; and one showed a sense of guilt plus anxiety.

Walker and Strauss (1939) suggest that the sexual impulse cannot be diverted into heterosexual channels in the case of the true invert and that psychotherapy—by a trained psychiatrist only—should be given to relieve the homosexual of a superadded neurosis and to re-educate him. This seems a very sound view. East and Hubert (1939) consider that the contraindications to treatment are repeated homosexual practices over many years; friendly but quite uninterested relations with women; the presence of other well-developed sexual perversions; and the presence of anti-social trends, whether in association with the practice of homosexuality or showing themselves in other ways. Dr. H. T. P. Young, late senior medical officer at Wormwood Scrubs Prison, states in the Report of the Commissioners of Prisons, 1942-4, that in 1943 19 prisoners convicted of sexual offences with males were unsuitable for psychotherapy for the following reasons: sentence too short, 5; intelligence too low, 6; constitutional psychopathy or organic lesion, 2; no genuine anxiety for cure, 4; other reasons, 2.

When considering the question of psychotherapy, so far as the 13 individuals in this series are concerned, facts were disclosed which will prove discouraging to those who advocate psychotherapy in all cases of homosexuality. No fewer than seven cases had had psychotherapy, and in every instance it had been administered at a well-known clinic or hospital, or by a well-known psychiatrist who has contributed to the literature on this subject. According to the patients, cures and improvements had been claimed and the courses had lasted for a considerable time and been repeated. And yet four of these "cures" found themselves in prison for the first time, having committed an overt homosexual offence. On the other hand, one of these prisoners reappeared for the fifth time. Of the remaining six cases none had had treatment. Three, however, had no desire for any, and said they would resist every inducement. One (Case 7) was too dull to be able to co-operate in any form of treatment, as well as having well-developed sexual perversions, and therapy was manifestly contraindicated. Another had already been considered by a clinic and a consultant psychiatrist and turned away as unsuitable. The last (Case 79) was an intelligent man with no previous convictions who had previously been well adjusted socially; his offence was directly attributable to heavy consumption of alcohol. A recommendation was made to the court that he might benefit from a psychotherapeutic course with a view to resolving his superadded emotional conflict and helping him to develop more socially useful tendencies. Thus out of 13 cases, in only one was there any indication that psychotherapy would be of any value whatsoever—and then only as a palliative, not as a cure. Five of the case histories are given below as illustrations.

**Case 7.**—Aged 32 years. Buggery; no previous convictions. A hotel porter by profession, he was a native of Eire and came

to London at the age of 20. There was no morbid family history. He could read and write, but was well below average intelligence. He had never had intercourse with women and was not attracted to them in any way. In 1936 he started to work at a famous London hotel and was "seduced" by a page-boy who persuaded him to have peno-rectal intercourse. He went to live with the boy and stayed with him for two years, regular intercourse taking place all the time. The prisoner always played the active part both at this time and subsequently. When he left this hotel and went to another, homosexual activity ceased for a time. During the war, while working at another famous London hotel, it was the custom for the staff to sleep in the ballroom during air raids. It was also the custom, he stated, for homosexual activity to occur. The prisoner found a boy who attracted him, and intercourse started and continued up to the time of arrest. Frequently he sought homosexual prostitutes—always boys—and had intercourse. He had nocturnal emissions, and the fantasy was of homosexual intercourse in which he played the active part with a boy partner. There were strong sadistic tendencies, and he enjoyed inflicting pain on his paramours. He had marked anxiety symptoms and suffered from a duodenal ulcer. His insight was fair, but psychotherapy was contraindicated on account of his backwardness and the evidence of strong perversions.

**Case 41.**—Aged 30 years. Importuning; no previous convictions. He was a bright, well-educated man who was a brilliant musician and seemed likely to be able to follow a career as a concert pianist. Unfortunately he had suffered from nerve deafness since the age of 15. He was very effeminate in physical appearance as well as in voice and mannerisms. At the age of 16 he was indecently assaulted in a public lavatory. He had never been attracted to the female sex and had never had heterosexual intercourse. Homosexual activity started at the age of 20, but previously he had masturbated and indulged in a fantasy of rough, physically strong men. He had never gone further than intra-erual intercourse and had played both active and passive parts. Strong guilt and anxiety were associated with the act, and because of this he sought the aid of a psychiatrist. Several years of treatment had had no effect either on the homosexuality or on the superadded neurosis. He was charged with importuning, and suggested that the exposure of what he called his "weakness" and the prospect of a prison sentence had been more beneficial than any previous treatment. In view of his previous lack of convictions a recommendation was made to the court that further treatment might help him to readjust himself socially.

**Case 79.**—Aged 48 years. Importuning; no previous convictions. This man was a fine-looking specimen, alert and intelligent, and a bank cashier by profession. He was single and supported an aged mother. He had realized he was a homosexual for as long as he could remember. He was not attracted to women, but was friendly with many and did occasionally dance with them. He had a sincere affection for his mother. Homosexual activity had only once gone further than mutual masturbation. He had on this occasion played the passive partner in peno-rectal intercourse, but was so revolted that it was never repeated. He had a strong guilt complex following mutual masturbation; the fantasy during nocturnal emissions was one of self-masturbation. He was charged with importuning and admitted the offence. He had, however, indulged over-freely in alcohol, and this was the first occasion on which he had ever committed such an act. He was allowed bail and attempted suicide before his appearance at court, but was saved by his mother. He had originally intended to murder her first, but found himself unable to do so, though he killed the cat as a start to wiping out the entire family. Considerable time was spent with this man before he went to court, and an attempt was made to re-educate him, with some success. It was strongly recommended to the court that therapy might help to alleviate his anxiety and sense of guilt and reorientate him to society.

**Case 85.**—Aged 64 years. Importuning; one previous conviction for the same offence. The prisoner was a well-educated, sensitive man of delicate feminine appearance, with long shapely fingers and finely chiselled features. He had studied medicine in his youth and was engaged to a young lady of

good family. When he began to study gynaecology he found he was disgusted by the sight of the female genitalia, though he said he rather "enjoyed" the labour ward and parturition. He had previously had homosexual relations, and he now realized his condition; his engagement was mutually terminated with no sense of disappointment on his side. He gave up medicine, as he had private means; for a time he occasionally indulged in mutual masturbation. He then went to live with an older man, and for ten years they lived in complete harmony as lovers. They both played active and passive roles. After he parted from this man he had gone to live with another, and had done so for nearly thirty years. At first he played both parts, but later became the passive partner and had always done this since. There was a strong masochistic flavour to the act, which he described in ecstatic terms. His disgust of the female genitals had gradually been transferred to females in general, and now the very rubbing against them in a bus made him feel "unclean." He was importuning because his partner was on holiday and he felt "sex-starved." He considered nothing could be done to help him, and had no desire for treatment.

*Case 91.*—Aged 42 years. Importuning; one previous conviction for the same offence. He had always been attracted to men, and started intercourse at the age of 20. He had never had a regular partner and had never associated with boys. His fantasy during nocturnal emissions was of the homosexual act with himself in the passive role. He had played both parts but much preferred the passive. He had served in the Forces and was demobilized with a good character. During his service he had married an A.T.S. girl; but intercourse occurred only twice, and he was so disgusted that he could face it no longer. The wife had gone to another man, by whom she had a child, and he let her go without interference. He had never had heterosexual intercourse on any other occasion and did not desire it again. He experienced a complete tumescence during homosexual intercourse, with detumescence at the time of the orgasm of the active partner. He occasionally had an emission with orgasm but described the "other sensation" he experienced as infinitely more pleasurable, and he felt an overwhelming love for the male partner. He had no wish to be altered, and said he would resist any attempt to do so.

There is a wide divergence of opinion on how to deal with men charged with homosexual offences. At one extreme there are those who consider that such offences merit the most severe penalties; these are mostly non-medical persons, and, to be fair, non-legal. At the other extreme are those who consider that imprisonment is completely contraindicated; these are mostly medical men, and psychiatrists at that. Walker and Strauss criticize severely the penal laws on this subject and suggest that, except in the case of offences against children, homosexuality should be tolerated. They consider that sentences of imprisonment for repeated sexual offences against children serve no useful purpose, and removal to a "protected environment" for an indeterminate period is recommended. It is difficult to see how this environment would differ appreciably from a prison sentence except for the increased length of sentence.

In Kenny's *Outlines of Criminal Law* the purposes of punishment are stated to be primarily deterrent, both to the offender and to others, and reformatory. Important subsidiary objects, however, are stated to be gratification of the injured person and satisfaction of the indignation of the community. In court it is often mentioned that laws were made for the protection of the community as a whole and not for the benefit of the individual; the parents of seduced children, in particular, demand retributive punishment for the offender. In offences of this nature imprisonment is more often imposed with retribution in view than in the case of other homosexual offences, where the reformatory value is stressed by the court. Comparison is often made between the law in this country and in other countries as it relates to homosexual offences. Is there in fact so much difference? All are agreed on the necessity for

preventing the seduction of boys, and seduction is prosecuted as vigorously in other countries as in this one. All the cases in this series committed overt acts and offended public decency. Covert homosexuality is rarely prosecuted, and I have not experienced a case in which two adult men were charged with committing homosexual acts behind closed doors. The public objects to witnessing such acts and is entitled to demand that they be suppressed.

The whole subject was admirably dealt with in a paper by East (1946). He stressed that if the modifications envisaged in the proposed Criminal Justice Bill were introduced a better understanding of the criminal by extramural psychiatrists and a wider conception of punishment as a method of treatment would be required. He also considered that, if psychiatric treatment of offenders is made a condition of a probation order, only psychiatrists of wide experience and mature judgment should undertake the work. These views were commended by Lord Cooper, the Lord Justice Clerk of Scotland, who ascribed the conflict between psychiatrists and lawyers to the fact that the former were not used to having their opinions questioned and the latter were not used to accepting other persons' conclusions unexamined. He further stated that the lawyer is not ready to accept the principle that there is a section of the community chosen by medical men whose members are free to commit crime with limited liability, or perhaps with no liability at all. To some this view may sound harsh, but it is imperative that the difference between legal responsibility and medical culpability be fully appreciated if psychiatrists are to take their proper place in helping to deal with offences of the nature discussed.

### Summary

The incidence of homosexual offenders received into Brixton Prison during 1946 is discussed. These numbered 96, and a classification into four groups has been made.

The date of the offences and the age and previous convictions of the offenders have been investigated and the results tabulated, brief comments being made.

The pseudo-homosexual group, the bisexuals, and the prostitutes are examined and brief case histories given.

The group of true invert, numbering 13, is discussed in more detail, particularly as to the effects of previous treatment. Seven had had treatment and had not shown improvement therefrom, three refused all interference, and only one of the remainder was considered likely to benefit.

A brief examination is made of the legal and social aspects of dealing with the homosexual offender and the relation of the psychiatrist.

The Minister of Health has adopted recommendations for increasing the salaries of midwives and mental nurses employed in part-time service as follows. If employed for not more than 30 hours a week: midwifery sister, S.C.M. and S.R.N. or R.S.C.N., 3s. 1d.; S.C.M. only, 2s. 11d.; staff midwife, 2s. 5d. or 2s. 3d. according to qualifications. If required to work on occasion for a few hours in excess of 30 a week payment for the additional hours is as follows: midwifery sister, 2s. 9d. or 2s. 7d. according to qualifications; staff midwife, 2s. 1d. or 2s. Mental nurses employed for not more than 30 hours a week: female ward sister, 3s.; female deputy sister, 2s. 7d.; female staff nurse, 2s. 5d. Payment for additional hours over 30 is as follows: 2s. 8d., 2s. 3d., or 2s. 1d. according to grade.

# SUDDEN DEATH AFTER INTRAVENOUS INJECTION OF A MERCURIAL DIURETIC ("NEPTAL")

BY

A. G. OETTLÉ, B.Sc., M.B., B.Ch.

(From the Department of Anatomy, University of the Witwatersrand, Johannesburg)

While mercurial diuretics are of great value in the symptomatic treatment of oedema the dangers associated with their use should not be forgotten. The most dramatic of these untoward reactions is sudden death, which occasionally follows directly on the intravenous injection of an organic mercurial. The case here recorded demonstrates this unexpected sequel.

## Case History

The patient, a married woman aged 31, was admitted to hospital on March 17 complaining of swelling of the legs (eight weeks), reduction in urinary output (five weeks), dull backache (five weeks), and haziness of vision (four weeks). She had suffered from frequent sore throat for many years, and four and a half years before admission had had an attack of rheumatoid arthritis which responded poorly to treatment with gold injections. In view of this complication the sore throats were regarded more seriously, and a tonsillectomy and complete dental clearance were performed three years previously in an unsuccessful attempt to cure the condition. Two months before her present symptoms appeared in December she underwent a ventrisuspension and appendectomy.

On examination the patient was seen to be a pale, sthenic, well-nourished woman with a generalized pitting oedema. Fine crepitations could be heard at both lung bases, and a small palpable gland was found in the right digastric triangle. The temperature and pulse were normal, the B.P. was 130/90, and the fundi were normal, without papilloedema, kinking of vessels, or exudates. A complete examination of all other systems revealed no abnormalities.

**Laboratory Investigations on Admission.**—March 18:—Urine: Albumin present, 0.55 g. per 100 ml. Microscopical examination revealed occasional hyaline casts, erythrocytes, pus, and spheroidal epithelial cells. Blood: Wassermann reaction negative; blood cholesterol, 440 mg. per 100 ml.; serum albumin, 2.4 g. per 100 ml.; serum globulin, 1.8 g. per 100 ml.; blood urea, 16 mg. per 100 ml. Blood count: Haemoglobin, 76%; red cells, 3,790,000; white cells, 8,400 (neutrophils, 54%; monocytes, 4%; lymphocytes, 38%; eosinophils, 4%). The urea clearance was 61% of normal. The diagnosis was subacute (nephrotic) nephritis (Type 2 of Ellis, 1942).

**Treatment and Progress Notes.**—The patient was confined to bed and given a diet high in protein and low in salt, with iron tonics. On March 19 she developed a left basal pleurisy, and this persisted until death. On March 21 she had an attack of rheumatic pain in both knees, lasting for one day. On the 2nd treatment with a mercurial diuretic ("neptal") was started: 0.5 ml. was given intramuscularly, and thereafter 2 ml. every second or third day, until by April 21 a total of 24.5 ml. had been injected. Good results were observed, diuresis varying between 50 oz. (1.42 kg.) and 110 oz. (3.12 kg.) after each dose. Ammonium chloride, 15 gr. (1 g.) t.i.d., was given orally at the same time. The injections of the diuretic were very painful, and as this pain could not be prevented by preceding the neptal by a local analgesic (procaine) the intravenous route was adopted, to the patient's relief. Two ml. was given intravenously on April 23, 25, 28, and 30. After the last injection she complained of giddiness, and became pale for a few seconds, shortly after the needle had been withdrawn.

On May 1 the patient complained of a sore throat and generalized joint pains. Her knees became swollen and a patellar tap could be elicited on both sides. On the 3rd 2 ml. of neptal was injected into the right median cubital vein, this taking about one minute to carry out. Immediately on withdrawing the needle the patient turned pale and fell back un-

conscious. Cyanosis rapidly supervened, and breathing, which had become gasping, ceased about two minutes after the onset of the attack. A convulsion occurred, with jerking of both arms, and the pupils became widely dilated before death. Artificial respiration was carried out, with intranasal oxygen for twenty minutes, and 1.7 ml. of nikethamide was given intramuscularly and the same dose intracordially, without avail.

The manner of death observed in this patient bore a close resemblance to that witnessed in another person dying of a terminal coronary infarct about the same time. Both of these patients displayed a syndrome of primary cardiac arrest followed by cyanosis, convulsions, and eventual cessation of respiratory movements. On clinical grounds, therefore, it appeared that the injection of neptal brought about a sudden cessation of the heart-beat, presumably by ventricular fibrillation.

**Necropsy.**—This revealed the large pale kidneys of subacute glomerular nephritis and a left-sided pleural effusion. A small adherent clot was present in one of the cubital veins, but no sign of embolism could be found. Chronic poisoning by mercury could be excluded as there was no stomatitis or haemorrhagic colitis. About 1 or 2 ml. of air was found in the heart. The most probable explanation is that this air was injected into the heart after death during the intracordial injection, for in performing this the needle first encountered lung and air was withdrawn into the syringe.

## Discussion

Since 1925, when Redlich drew attention to three fatalities after intravenous injections of a mercurial diuretic ("novasurol"), more than a score of deaths attributable to this cause have been recorded. Although the deaths reported by Redlich do not appear to have been directly due to the mercury (one died of a Jarisch-Herxheimer reaction, another from salvarsan encephalitis, and the third—Redlich's own case—from an intestinal obstruction) his report does seem to have stimulated interest. Numerous subsequent cases have been recorded in which the mercurial has been more convincingly incriminated, and from these cases and the animal experimentation which they stimulated it is now possible to come to definite conclusions about the immediate action of mercurials on the heart. These findings are summarized below.

### 1. Type of Patient

Sudden death after an injection of a mercurial diuretic has occurred in children as well as in young, middle-aged, and elderly patients suffering from such varied conditions as nephritis, nephrosis, cirrhosis of the liver, and heart disease of rheumatic, syphilitic, congenital, coronary, or hypertensive origin. DeGraff and Nadler (1942) have stated that inflammatory disease of the kidney is a contraindication to the use of mercurial diuretics: certainly most of these accidents occurred in cases of nephrosis and Type 2 nephritis, and Evans and Perry (1943) suggest that a lowered plasma protein may be a factor of significance. Nevertheless this toxic effect has been demonstrated on healthy experimental animals, and it would seem that death is the result of a direct action on the heart.

### 2. Type of Diuretic

In human cases "salyrgan" and "mercupurin" have caused most of the deaths (Ben-Asher, 1945; Sundaram, 1934; Brown *et al.*, 1942; Barker *et al.*, 1942), but deaths are also reported following "esidrone" (Volini *et al.*, 1945), "mersalyl" (Evans and Perry, 1943), and neptal (Greenwald and Jacobson, 1937). Animal experiments also demonstrate variation in toxicity, esidrone and mercupurin being singled out for especially unfavourable mention by Pines *et al.* (1944). DeGraff and Lehman (1942) found that esidrone was more toxic to cats than either mercupurin or salyrgan. Nevertheless on theoretical grounds it seems likely that any organic ionizable mercurial diuretic will be capable of producing sudden death of this type.

### 3. Route of Administration

So far all but one of the deaths have followed an intravenous injection, the exception being the case of Wolf and Longiorno (1931), in which an intraperitoneal injection was to blame. It should be borne in mind, however, that DeGraff and Lehman were able to kill dogs with large intramuscular doses: in humans, therefore, it is possible that fatal reactions may also follow intramuscular injections of the mercurial, though this is very unlikely, since rapid elimination would normally prevent the injection from reaching toxic levels.

### 4. Cause of Death

The manner of death in all these cases has been almost identical. Apparently the heart stops beating before the respiration ceases, and convulsions occur which are probably due to anoxia. This usually takes place within a few minutes of the injection, though in one instance as much as half an hour elapsed before the terminal episode.

Death may occur after the first injection. This has been reported four times—viz., by Sundaram (1934), Cadbury (1936), Barker *et al.* (1942), and Volini *et al.* (1945). These four cases are of great significance, for their occurrence excludes the possibility of cumulative poisoning with mercury as a cause of death, and also rules out anaphylaxis or sensitization, both of which have been considered (Tyson, 1941; Evans and Perry, 1943; Rennie, 1945) in spite of the absence of any clinical evidence in favour of these diagnoses.

Hyman (1942) suggested that these patients died from "speed shock"; but this cannot be accepted, as the clinical picture of "speed shock" is different (salivation, vomiting, diarrhoea, irregular respiration, fall in blood pressure, and bronchospasm). Conclusive evidence to the contrary is provided by Wexler and Ellis (1944), who demonstrated that blood drawn from the patient immediately after death was capable of clotting, since in "speed shock" such blood will be found to be incoagulable.

A considerable weight of evidence has been accumulated to indicate that these deaths are due to the direct toxic action of the mercury ion on the heart. This action was first demonstrated with inorganic salts of mercury by Salant and Kleitman in 1922; they showed that the mercury ion was capable of inducing ventricular fibrillation, which neither bilateral vagotomy nor atropinization could alter. Salant and Brodman (1929) state that adrenaline improves the heart poisoned by mercury while ergotamine increases mercurial toxicity. The same action was demonstrated in the organic mercurial diuretics by Jackson, who in 1926 produced ventricular fibrillation in dogs with salyrgan. His work has been confirmed by other investigators with other diuretics (DeGraff and Lehman, 1942; Pines *et al.*, 1944). From his experiments on the isolated turtle heart Johnston (1941) came to the conclusion that the toxic action of the organic mercurial diuretics was a side action related to their mercury content, and consequently was not essentially different from that of inorganic salts like calomel and bichloride of mercury.

However suggestive they might be, animal experiments alone could not prove that human fatalities were also the result of ventricular fibrillation. This final step has been completed by the unique studies of Volini, Levitt, and Martin in 1945; for in two of their three patients killed by mercurial diuretics simultaneous electrocardiograms were obtained which demonstrate that ventricular fibrillation was the cause of death.

The unpredictable behaviour of the drugs still remains to be explained. Some patients die at the first injection, while others receive many injections only to succumb after

an injection differing apparently in no way from its harmless predecessors—for example, the patient of Wexler and Ellis's (1944) who received a total of 164 ml. before the fatal dose of mercupurin, or the case reported by Barker *et al.* (1942) in which it is estimated that more than 200 injections of mercurial had been given before the one that proved fatal.

### 5. Premonitory Indications

The occurrence of subacute reactions after any injection of mercurial diuretic should be regarded seriously, and would indicate the need for smaller doses or a different route of administration. Unfortunately such warning is not always given. The case history recorded above demonstrates one warning the significance of which was not appreciated at the time—namely, the attack of giddiness after the penultimate injection. In three out of the four cases quoted by Brown and co-workers (1942) warning symptoms were observed at previous injections. These included dyspnoea, orthopnoea, sweating, pallor, bradycardia, and syncope. Wexler and Ellis have described the immediate non-fatal reactions as of four types: (1) a subjective, indescribable, unpleasant sensation; (2) transitory dyspnoea; (3) apprehension, substernal discomfort, slight increase in respiration and pulse rate, and orthopnoea; (4) moderate collapse, cyanosis, and sweating. The occurrence of any reaction should receive serious consideration.

### 6. Treatment

In human cases recovery is rare. Tyson (1941) reports the case of a young male nephrotic who became unconscious after 1 ml. of esidrone, with a convulsion, deep cyanosis, dilated pupils, and absent heart sounds. This patient recovered after artificial respiration, adrenaline, nikethamide, and aminophylline had been administered. Andrews (1931) reports a similar case of recovery in a young woman with rheumatic valvular disease, in which consciousness was lost, but the heart did not stop beating, although seriously affected.

On the isolated turtle heart Johnston (1941) found that nikethamide was of no use in treatment but that sodium thiosulphate would restore to normal rhythm a poisoned heart in complete block. Further, if perfused at the same time, this substance would prevent the action of the mercurial. DeGraff and Lehman have confirmed this for the cat. To apply this fact to the treatment of the human being poisoned with a mercurial diuretic would be difficult, although possible. Fortunately, prevention of fatalities is considerably easier than cure.

### 7. Prevention

The discontinuance of these drugs has never been suggested. A proper perspective of their toxicity will be obtained if it is realized that even when given intravenously they are less toxic than the arsphenamines (DeGraff and Nadler, 1942).

*Route of Administration.*—In his textbook White (1944) says that the mercurials are "preferably given intravenously" (p. 783); nevertheless since all recorded fatalities have followed intravenous and intraperitoneal injection of these drugs, these two routes should be used no longer. The pain of intramuscular injections might be prevented by infiltrating the injection site with an anaesthetic of long duration, such as "proctocaine."

*Choice of Drug.*—Esidrone, salyrgan, and mercupurin have been mentioned most frequently as causes of death. They might well be avoided unless it is proved that this frequency was due to their popularity rather than their extra toxicity.

*Adjuvants.*—Pines and co-workers (1944) found that if 0.5 ml. of 20% magnesium sulphate was injected

simultaneously one could prevent the onset of ventricular fibrillation in dogs even when seven times the normal lethal dose was given. This has considerable clinical significance. Magnesium sulphate should be added to all mercurial diuretics intended for injection. Theophylline is of proved value as an adjuvant, for it not only increases the rate of renal excretion of the mercurial but also serves to reduce the toxicity of certain of these compounds (DeGraff and Nadler, 1942); nevertheless deaths have occurred in spite of its presence.

**Other Drugs.**—The common cardiac drugs, digitalis, aminophylline, ammonium chloride, and phenobarbitone, have no effect on the toxicity of mercurials (DeGraff and Nadler, 1942).

**Rate of Injection.**—Contrary to what might be expected, DeGraff and Lehman (1942) found that injecting the mercurial slowly only increased its toxicity. They demonstrated in cats that the slower the injection the smaller the lethal dose, the curve flattening out at a rate of 40 minutes per ml., at which point the toxicity was about three times that of a rapid injection. Human cases have confirmed that dilution is of no value, and fatalities have been reported with dilutions of 1 in 10 (Sundaram, 1934; Barker *et al.*, 1942; Evans and Perry, 1943).

### Summary

A case is presented in which sudden death followed the intravenous injection of a mercurial diuretic. Death is presumed to have been due to ventricular fibrillation.

Similar cases are described in the literature, also following the intravenous injection of these drugs. Treatment should consist of intracardiac adrenaline and sodium thiosulphate.

To prevent such sequelae mercurial diuretics should never be given by the intravenous route. The addition of magnesium sulphate to the injection promises to lower its toxicity considerably.

I wish to thank Prof. W. H. Craib for permission to publish this case. I am grateful to Prof. A. S. Strachan and to Dr. Laubser, then of the Medico-Legal Laboratory, Johannesburg, for their interest and assistance, and to Dr. M. McGregor for his criticism.

### PLUNGE BATH FOR CASES OF POLIOMYELITIS

The present increase in the number of patients suffering from anterior poliomyelitis has presented problems of treatment not ordinarily encountered in general hospital practice. An underwater therapy pool was constructed within three weeks at the County Hospital, Farnborough, Kent, and the following description by the hospital steward may prove of interest.

To meet an emergency, application was made to the Kent County Council Public Assistance Officer to utilize a building which had formerly been devoted to casual ward accommodation. Permission was promptly given, and in less than three weeks the building was converted into a plunge bath 11 ft. 6 in. (3.5 m.) by 8 ft. 6 in. (2.6 m.) to be used for the underwater treatment of patients suffering from anterior poliomyelitis.

This was effected by constructing a small dam wall across the width of the room and making the walls and floor watertight. The bath is filled with water of the right temperature through a mixing valve, and in order that it may be maintained at a continuously even temperature a thermal control unit has been installed. The bath may be filled to a depth of 3 ft. 6 in. (1 m.) and is equipped with hand rails, slings, etc. An adjoining room has been fitted with dressing cubicles.

The facilities thus provided make it possible to deal with several patients at the same time instead of singly, and the bath replaces an emergency collapsible water dam which was kindly loaned and erected by the Bromley N.F.S. at short notice.

The whole of the work was carried out by the hospital engineering and maintenance staff with the valued advice of the County Architect's Department.

DAVID P. NICHOLSON, M.D., M.R.C.P.

*Pædiatric Registrar,  
County Hospital, Farnborough, Kent.*

A circular from the Ministry of Health on the transfer of headquarters hospital staffs to the Regional Hospital Boards under the National Health Service Act points out that the transfer concerns those officers employed immediately before the appointed day "solely or mainly at or for the purposes of any hospital transferred to the Minister" (other than teaching hospitals). Local authorities have been asked for a statement of the numbers and types of staff employed on such work for more than half their time who would be liable for transfer. Many authorities, however, have found it impossible to provide a satisfactory list on this basis. The circular suggests, therefore, that they must relate the number of staff transferred to the amount of work transferred and assess the part of the work in terms of units of staff in different grades. The estimate will be only approximate but should afford both a reasonable guide to the Regional Hospital Board's requirements and a general formula for providing lists of officers for transfer. Replies should reach the Ministry by Oct. 30.

## Reviews

### CONSIDER THE MOUSE

*Animal Genetics and Medicine.* By Hans Grüneberg, Ph.D., M.D. With foreword by Sir Henry Dale, O.M., G.B.E., F.R.S. (Pp. 296; 33 illustrations. 21s.) London: Hamish Hamilton Medical Books. 1947.

Dr. Grüneberg is to be warmly congratulated on having written a book which we may expect to have a profound influence on medical research in the immediate future. He is well known among geneticists as one who, excelling both in genetics and in medicine, has devoted his outstanding intelligence, technical skill, and knowledge to the most careful and comprehensive study of the gene in action in the production of pathological characters in the mouse and rat. He is at once geneticist, embryologist, anatomist, and pathologist, and in addition is a writer of clear, concise, and attractive English. In writing this book he had two main aims. One was to demonstrate that there are a considerable number of inherited conditions in rodents of which some are very similar to clinical entities in man. The other was to show that the study of conditions which have no known close counterparts in man can reveal new aetiological mechanisms which may help us to understand human diseases apparently very different from them. He achieves both these aims and goes far towards proving his contention that the systematic and co-ordinated study of inherited diseases in these animals should be considered a new branch of medical science.

Often in the search for the causal factor of disease and for an understanding of the ways in which this cause effects its result man himself is not the best experimental material. Often in medicine a variety of conditions are grouped under a common diagnostic label, and conversely the same disease aetiologicaly is classified under more than one name. This criticism does not apply to inherited diseases in the experimental animal. In the case of man the interplay of nature and nurture in the causation of a disease commonly makes it exceedingly difficult to determine which of the two plays the major part. The circumstances of the experimental animal's environment can be stabilized. In man an obvious and simply inherited pathological condition is rare, while in the experimental animal it can be produced in any number desired, since matings can be controlled. Little can be known in man of the early stages in the development of a pathological condition of this kind, whereas a series of experimental animals can be killed at any stage and the sequence of events recorded in their proper order.

In medicine active research is proceeding to determine the causes and the manner of development of diseases of the different organ systems. In the field of genetics similar and allied mutant conditions are regarded as inherited characters of interest and usefulness, since they are so easily recognized and traced in their transmission through the generations. At the present time there is insufficient liaison between these two fields of activity, with the result that genetics cannot yet make its maximum contribution to the solution of medical problems. For example, the paediatrician is interested in harelip and cleft palate as a problem in clinical medicine. Would it not profit him to consider the mouse, in which this condition is a well-recognized genetical entity?

The following conditions are extracted from the text of Dr. Grüneberg's book as illustrations of the great attractions it offers to those whose material is the human subject. In the mouse: pseudo-encephaly, spina bifida, absence of the corpus callosum, otocephaly, hydrocephaly, epilepsy, coloboma retinae, macrocytic anaemia, siderocyte anaemia, polydactyly, stenosis of the oesophagus, imperforate vagina, and hypotrichosis cystica. In the rat: epilepsy, microphthalmia, diabetes, siderocyte anaemia, and congenital cataract. In the rabbit: syringomyelia, otocephaly, spastic spinal paralysis, epilepsy, coloboma retinae, congenital cataract, keratitis, chondrodystrophy, homeotic variations of the vertebrae, hypospadias, and hyperkeratosis cutis et follicularis. In the guinea-pig: otocephaly, microphthalmia, and chondrodystrophy. A long list of other eye, foot, skin, kidney, and tooth anomalies, locomotor disturbances, and endocrine disorders in one or more of

these different species could be given. All these conditions have been demonstrated to be genetically caused, and, as Dr. Grüneberg points out, the action of the genes concerned upon the processes of development or upon those of degeneration can be quite easily followed by appropriately designed investigations. Manifestly it would be greatly to the advantage of an embryologist, pathologist, or clinician considering these or similar conditions in man to undertake or to encourage parallel investigations with the most suitable animal material.

This is indeed an exciting book, provocatively written and easily sustaining this thesis, which surely must be of the greatest interest to all engaged in advancing medical science. It is a thousand pities that the circumstances of the times have made it necessary for the publishers to use a paper unworthy of the subject matter that it bears and to price the book beyond the means of many who would wish to possess it.

F. A. E. CREW.

### TEXTBOOK OF ALLERGY

*Allergy in Theory and Practice.* By Robert A. Cooke, M.D., Sc.D., F.A.C.P. (Pp. 572; illustrated. 40s.) Philadelphia and London: W. B. Saunders Company. 1947.

In writing this book Dr. Cooke has had the assistance of 13 collaborators, most of whom are well known from their previous publications. Their aim has been to record the facts of allergy and, "while realizing the existing limitations of information and possible errors of interpretation," to co-ordinate them. The authors have considerable practical experience and largely accomplish their intention. Nomenclature is discussed clearly and straightforwardly. Walzer gives a good account of skin testing. Chobot considers that desensitization to food is ineffectual, and regards the value of the oral method with drop-by-drop increases as unproved. Writing on urticaria, Cooke states that 35% of the cases which attend for diagnosis are due to infection, 10% to foods, and 10% to drugs, while the aetiology of the remaining 45% is at present unknown. Asthma is classified as non-infective and infective.

Dr. Cooke pleads in a foreword that allergy be given its due place in the curriculum of medical schools. The basic principles should be taught during the earlier years of training. In the clinical years a few lectures, perhaps four, might be given, and a case of allergy allocated occasionally to the student so that he might learn how to take an adequate history of this kind and be initiated into the special techniques used. All that Cooke says applies equally to Britain. Allergic disease is probably just as common here as in America, where 7 to 10% of patients in general practice are said to present problems in allergy. This is a well-composed and reliable textbook of allergy for the postgraduate.

D. A. WILLIAMS.

### TREATMENT WITH HEPARIN

*Heparin in the Treatment of Thrombosis. An Account of its Chemistry, Physiology and Application in Medicine.* By J. Erik Jorpes, M.D. Second edition. With foreword by Prof. J. R. Learmonth, Ch.M., F.R.C.S. Ed. Oxford Medical Publications. (Pp. 260; illustrated. 18s.) London: Geoffrey Cumberlege (Oxford University Press).

In recent years the prevention and treatment of thrombosis by natural and synthetic anticoagulant substances have attracted considerable attention, particularly in America and the Scandinavian countries. The present monograph, written in excellent English, is by a foremost Swedish authority on this subject. Dr. Jorpes is a biochemist, but in his book he reveals a remarkable knowledge of the clinical and social problems associated with thrombo-embolic conditions. The book is in two parts: the first devoted to "The Chemistry and Physiology of Heparin," and the second to "Heparin and Thrombosis." The first half will be of greater interest to physiologists and biochemists than to clinicians, though the latter will welcome the fine tribute which the author pays to Howell's pioneer work, the fascinating story of the work which led to the conclusion that the mast cells of Ehrlich are responsible for the production of heparin, and the explanation of the difficulties that have to be overcome in preparing and standardizing heparin. In this connexion it is gratifying to note that due credit is given to the work done by Best, Murray, and others in Toronto.

In the second half of the book Dr. Jorpes discusses the use of heparin in the prophylaxis and treatment of thrombosis. Considering principally the problems of post-operative thrombosis and pulmonary embolism, he presents statistics from a large number of Swedish clinics which show that heparin can very considerably reduce the mortality and morbidity from these conditions. He advocates intermittent intravenous injection rather than continuous heparinization by infusion as the method of administration, and those interested will find adequate information on dosage and duration of treatment. He also discusses the use of heparin in thrombosis of the retinal veins, mesenteric thrombosis, subacute bacterial endocarditis, vascular surgery, and the prevention of pleural and peritoneal adhesions. Although the book is primarily about heparin, the author devotes two chapters to the synthetic anticoagulant dicoumarol. He has less personal experience with the use of the latter, but nevertheless his warning against the indiscriminate use of a drug which produces "a kind of toxic narcosis of the liver cells, the depth of which is difficult to control" is well justified. Surgeons and others interested will find that the book is also a valuable source of information on the incidence of thrombosis and the mortality from pulmonary embolism.

This is an authoritative and timely monograph. The evidence presented ought to stimulate clinicians interested in these problems to press for the production of adequate and cheap supplies of a reliable heparin preparation in this country. The book is well produced, but it is disappointing to find several discrepancies between the references in the text and the bibliography.

R. L. RICHARDS.

### LABORATORY METHODS

*Chemical Methods in Clinical Medicine. Their Application and Interpretation with Techniques of Simple Tests.* By G. A. Harrison, M.D., B.Ch. Third edition. (Pp. 630; 5 colour plates and 120 illustrations. 40s.) London: J. and A. Churchill. 1947.

The new edition of this standard work incorporates accounts of the latest laboratory methods. Dr. Harrison has added much new material, maintaining the usefulness of the book without unduly enlarging it. His own experience has evidently guided him in making the alterations, and this enhances their value. As he mentions in the preface, the book is also his own "journal" and includes observations that might have been the subjects of special papers. Laboratory workers and clinicians will find many aids to interpretation, though the author comments, "There is a reasonable chance of interpretation of analyses being correct only if essential clinical findings are known. . . ." He is well qualified to emphasize the principles which such interpretations should be based.

Innovations include references to situations in which laboratory analysis may be used to control treatment, and a discussion on fluid therapy and its control. The author has revised the subject of body pigments and included a new chapter on the pathological pigmentations. He gives a more critical and up-to-date interpretation of the value of the van den Bergh reaction and of gastric analysis. He displays much originality, and we would note particularly the account of modifications to standard instruments used in his own laboratory.

Though the author has devoted much space to recent advances, he still stresses the more fundamental and simple observations on urine and faeces which are of such importance in clinical pathology. More emphasis on the use of milli-equivalents per litre would have been appropriate at this time in those passages where electrolytes in body fluids are discussed. Study of this book will help clinicians to understand more completely the work done by the clinical laboratory.

G. PRUNTY.

Dr. Arnold John Teal claims in *Water Supplies, Hepatitis, Associated Diseases and Fungi Infested Water in Assam* (Jorhat, Assam: Doss and Co.; Rs. 2.8) that infective hepatitis in Assam and North Bengal is a "water virus" disease affecting to a variable extent all the endocrine and secretory glands, the heart, and the nervous system. He states that in almost all cases the disease starts at birth, reinfection continues in varying degrees until death, and often many general and tropical diseases are secondary to it. He provides no valid evidence in support of these convictions. There is little in this monograph to commend it.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Diseases of Metabolism.* Edited by Garfield G. Duncan, M.D. 2nd ed. (Pp. 1,045. 60s.) Philadelphia and London: W. B. Saunders Company. 1947.

Includes new material on the thyroid gland, disorders of the kidney, fluid balance, disturbances in nutrition, and folic acid.

*Therapeutic Exercise.* By H. F. Ewerhardt, M.D., and G. F. Riddle, B.S., R.N., R.P.T. (Pp. 152. 12s. 6d.) London: Henry Kimpton. 1947.

A manual for students of physical education, occupational therapy, and physical therapy.

*Roentgen Interpretation.* By G. W. Holmes, M.D., and L. L. Robbins, M.D. 7th ed. (Pp. 398. 35s.) London: Henry Kimpton. 1947.

Outlines the interpretation of x-ray photographs, with many illustrations.

*Occupational Diseases of the Skin.* By L. Schwartz, M.D.; L. Tulipan, M.D., and S. M. Peck, B.S., M.D. 2nd ed. (Pp. 964. 63s.) London: Henry Kimpton. 1947.

An account of industrial skin diseases, their prevention and treatment; with illustrations, bibliographies, and a list of chemicals known to be skin irritants.

*Methods of Diagnosis.* By L. Clendening, M.D., F.A.C.P., and E. H. Hashinger, M.D., F.A.C.P. (Pp. 868. 63s.) London: Henry Kimpton. 1947.

After discussing the general principles of diagnosis, the author considers history-taking, examining each region of the body, and laboratory procedures.

*Modern Treatment Year Book 1947.* Edited by Sir Cecil Wakeley, K.B.E., C.B., D.Sc., F.R.C.S., F.R.S.Ed., F.A.C.S., F.R.A.C.S. (Pp. 354. 15s.) London: The Medical Press. 1947.

Includes articles on the treatment of influenza, of a premature baby, of gonorrhoea and syphilis, of acne, and of myasthenia gravis.

*The Doctor's Job.* By Carl Binger, M.D. (Pp. 243. 12s. 6d.) London: George Allen and Unwin. 1946.

An account for the layman of recent advances in medicine.

*Trial of Thomas John Ley and Lawrence John Smith.* Edited by F. Tennyson Jesse, F.R.L.S. (Pp. 313. 15s.) London: William Hodge and Co. 1947.

An account of the "chalk-pit murder."

*Utility Nurse.* By Margaret Crisp. (Pp. 101. 5s.) London: Chaterson, Limited. 1947.

The life of a Red Cross nurse in wartime.

*Physical Treatment of Injuries of the Brain and Allied Nervous Disorders.* By K. M. Hearn, M.C.S.P. (Pp. 96. 10s. 6d.) London: Baillière, Tindall and Cox. 1947.

Describes the methods of treatment employed at the Military Hospital for Head Injuries, Oxford.

*Obstetrical Practice.* By Alfred C. Beck, M.D. 4th ed. (Pp. 966. 38s. 6d.) Baltimore: The Williams and Wilkins Company. 1947.

Includes new material on analgesia and anaesthesia, penicillin in the prevention of congenital syphilis, and implantation of the ovum.

*Health the Unknown.* By John Comerford. (Pp. 144. 7s. 6d.) London: Hamish Hamilton. 1947.

An account of the Peckham Health Centre.

*British Surgical Practice.* Vol. 1. Edited by Sir Ernest Rock Carling, F.R.C.S., F.R.C.P., J. Paterson Ross, M.S., F.R.C.S., et al. (Pp. 486. £3.) London: Butterworth and Co. 1947.

Includes articles on abortion, achlorhydria and appetite, adiposity, allergy, amoebiasis, and artificial limbs.

*Retropubic Urinary Surgery.* By Terence Millin, M.A., M.Ch. F.R.C.S., F.R.C.S.I. (Pp. 208. 25s.) Edinburgh: E. and S. Livingstone, Limited. 1947.

A monograph on the author's retropubic approach to various surgical problems, with many illustrations, some in colour.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 4 1947

## THE CONTROL OF AIR-BORNE INFECTION

It has been evident for years that modern sanitation, so successful in almost every other field, has made comparatively little impression on the problem of air-borne infection. This is not the fault of neglect, since the subject has been studied on a steadily increasing scale for the past twelve years, and with added urgency and vigour during the war. The problem has been more accurately defined by most illuminating studies of the mechanism of air-borne infection, and remedies have been sought in two main directions: the mechanical removal or suppression of infected particles, and the disinfection of air by physical or chemical means. There is now abundant information about what can be achieved by such methods, and it is not too soon to inquire how useful they are likely to prove in various circumstances. The lecture to the Royal College of Surgeons by Prof. R. J. V. Pulvertaft, printed in the opening pages of this issue of the *Journal*, is such an assessment of the present position. His conclusions may be compared with those of two official pronouncements which have recently appeared in the U.S.A., entitled "The Present Status of the Control of Air-borne Infection," and "Dust and its Control as a Means of Disinfection of Air."<sup>1</sup> These are condensed and well-documented reviews prepared by influential committees of the American Public Health Association, which evidently feels that some guidance is called for in these matters.

The hospital ward containing patients infected by readily cultivable and recognizable bacteria such as haemolytic streptococci has been a fruitful field of study, and poses the problem of air-borne infection in its most definite form. Conclusions reached and remedial methods employed in this environment may well be applicable to others, more particularly sleeping quarters generally, but it is helpful first to define our knowledge of how to prevent cross-infection in wards. As Pulvertaft points out, there are two distinct ways of doing this, one being to protect the air from contamination, and the other to disinfect it. Measures directed to the first of these objects are the wearing of efficient masks, controlled ventilation, and the suppression of dust. The designers of future hospitals will require very definite advice on the subject of ventilation; more particularly they will want to know whether a simple abundance of fresh air is all that is needed, or whether it is necessary to control the direction of air currents. It should be easy to avoid the common and dangerous error of ventilating operating theatres by extraction fans, which results in air being sucked in under doors carrying floor dust with it. But what are the necessary applications of the opposite

principle, studied by Bourdillon—the production of a positive pressure of filtered air over the patient, so that air travels from him to possible sources of infection and not *vice versa*? It is doubtful whether any feasible system of ventilation will remove the necessity for separate measures directed to the suppression of dust. Opinion is unanimous that these are necessary, readily feasible, and effective. The system of oiling floors and fabrics first introduced in this country appears to have been brought to a high degree of technical perfection in the U.S.A., and the American report on dust control already cited strongly endorses its value.

An alternative or additional method is to disinfect the air itself. With certain reservations this is practicable by several methods. Ultra-violet light is the simplest and cheapest of these. It is generally applicable only to the upper air of inhabited rooms, since direct exposure to the light is harmful; but it seems to have been successful in diminishing the spread of infectious disease in schools and elsewhere. Chemical disinfection is also feasible by means of exceedingly low and, so far as is known, quite harmless concentrations of sodium hypochlorite, phenolic substances such as hexyl resorcinol, lactic acid, or triethylene glycol. The last named has been the subject of intensive study in the U.S.A., where methods have been perfected for producing the required concentration in the air, and even for regulating it automatically, the apparatus concerned being known as a "glycostat." Triethylene glycol depends for its full effect on a fairly high relative humidity. Hamburger and his colleagues<sup>2</sup> have shown that this is not an essential condition. During a period of fine weather with low humidity they were able by means of triethylene glycol to reduce the haemolytic streptococci in the air of an Army hospital ward by 88% during quiet periods and 54% during bed-making: it should be added that all the patients in this ward were nasal streptococcus carriers, selected and admitted for the purpose of these tests. But this result was made possible only by the simultaneous employment of dust-control measures, including the oiling of floors and bedclothes. Air disinfection is chiefly effective against the finer particles directly expelled from the air passages; indeed, most of the evidence of its efficacy is based on experiments in which bacteria were sprayed as fluid droplets. Against larger particles classifiable as dust it is not so dependable.

What is the practical usefulness of such measures as these? The American report does not venture to pronounce judgment on the respective merits of ultra-violet light and triethylene glycol as air disinfectants. It is, on the other hand, very definite about the possible scope of usefulness of either. There is a strong case for using them in controlling air-borne infection in hospitals, and particularly in fever and children's wards. In schools, barracks, and "specialized industrial environments" their general use is not justified until further knowledge has been gained, and "homes, offices, and places of public congregation" are placed in a third category as even less suitable for such attempts. These are in general the conclusions reached by Pulvertaft, but he makes a useful point in distinguishing between adults and children, regardless of environment,

<sup>1</sup> *Amer. J. publ. Hlth.*, 1947, 37, 353.<sup>2</sup> *J. infect. Dis.*, 1945, 77, 177.

because the latter have less immunity and "spend much of their time in homogeneous groups." If a beginning is to be made outside the hospital sphere the school is certainly the place for it. He also points out that measures would be justified during a pandemic of a new or rare infection—or, it might be added, during a severe epidemic of any infection—which are not called for under ordinary conditions.

It is disappointing that all this effort should apparently have brought us no nearer to diminishing the incidence of the common cold, or to improving the sanitary quality of the atmosphere in public places. Colds and other non-specific infections of the air passages are far more important in terms of discomfort and loss of time and efficiency than any of the more dangerous infections which we are now so well able to control. Pulvertaft is probably right in concluding that conditions in crowded public transport vehicles are sometimes such that no known method of air sterilization could possibly operate. But his argument that constant exposure to infection is necessary to immunity, and therefore, presumably, that conditions may just as well be left as they are, is a counsel of despair. It is a poor sort of immunity that is bought at the cost of two or three colds per annum, which are the lot of the average individual. That these are natural and inevitable under urban conditions we refuse to believe. It is of course not yet by any means certain that aerial transmission is the only, or even the most important, factor in the spread of the common cold. In so far as it is, better air sanitation in densely populated places is much to be desired, and the efforts of the past twelve years will not have attained full success until this aim has been achieved.

### BRITISH ANTI-LEWISITE

Although much work was done during the war both in this country and in the U.S.A. on weapons of chemical warfare, these weapons were not used. The work, however, proved of value in an unexpected direction, for no fewer than three discoveries were made in the field of new medicaments. We have recently learnt of the benefit given by "nitrogen mustard" to patients with leukaemia and with Hodgkin's disease; we are learning of the treatment of myasthenia gravis by di-isopropylfluorophosphonate; and, most important of all, BAL or dimercaptopropanol is now soundly established as a means of treating poisoning by arsenic. We reviewed work on this substance in a leading article about a year and a half ago.<sup>1</sup> There is evidence that it can be used for treating poisoning by mercury and gold as well. A report is found on another page in which a committee of the Medical Research Council gives its blessing to this new therapeutic agent, the report being based on the results obtained in 44 cases of arsenical dermatitis. This report confirms what was already known from work done both in this country and in the U.S.A. Carleton, Peters, Stocken, Thompson,<sup>2</sup> and their colleagues described their first observations on the effect of BAL in arsenical dermatitis, undertaken because it had been shown that

BAL reversed the toxic action of mapharside in animals. They found that in some cases the dermatitis disappeared within five days, and that in about half the 30 patients there was substantial benefit. At the Johns Hopkins Hospital, Longcope, Luetscher, Wintrobe, and Jäger<sup>3</sup> obtained results entirely similar, noting that patients in whom dermatitis occurred after three or more doses of arsenic recovered with unexpected rapidity when treated with BAL. Luetscher, Eagle, and Longcope<sup>4</sup> found a "consistent increase" in the urinary excretion of arsenic after treatment of dermatitis with BAL, corresponding "with the good clinical response of these patients."

Less good results are obtained so far as other symptoms produced by arsenic are concerned. The most extensive account is that of Eagle and Magnuson,<sup>5</sup> who have examined 227 cases; of these, 55 were suffering from encephalitis, and the effect of BAL in improving their condition was uncertain; of 14 patients with jaundice, 7 were not improved by BAL, but 5 were improved; the blood bilirubin fell in 3 of these. On the other hand, of 11 patients with arsenical agranulocytosis 10 were rapidly improved by BAL with an increase in total white count and in polymorphs; of 44 patients with fever due to arsenic therapy most were restored to normal by BAL. In this series the usual good effect of BAL was obtained in dermatitis.

Perhaps the next most important use of BAL is for the treatment of mercury poisoning. As its chemical name, dimercaptopropanol, implies, BAL is a substance which can capture mercury; this was demonstrated in animals by Gilman and his colleagues,<sup>6</sup> who found that BAL was active against mercury, as against arsenic, even when treatment was delayed. Thus dogs receiving 4 mg./kg. of mercuric chloride intravenously, a dose which was invariably fatal when given alone, were completely protected from the renal effects of mercury by three doses of BAL when treatment was delayed for 30 minutes. The clinical application of this result was successfully demonstrated by Longcope and Luetscher,<sup>7</sup> who treated 23 cases of acute poisoning with corrosive sublimate. Nine patients took from 1.5 to 20 grammes of mercuric chloride, 5 of the 9 having swallowed more than 1.5 grammes. Eight patients were treated with BAL from one and a quarter to three and a half hours after taking the mercury and recovered completely in two and a half to seven days. One patient was first treated 19 hours after having swallowed at least 1.5 grammes, and was entirely well in 3 weeks. In treatment BAL was given by intramuscular injection, the first dose being 0.3 gramme, or 3 ml. of a 10% solution. The total given in the first 12 hours was 0.45-0.75 g., and in the whole course of three to four days, 0.9-2.87 g.

Few people swallow corrosive sublimate, but occasionally fatalities occur after the injection of mercurial diuretics, as in the case recorded at page 530 of this issue of the *Journal*. These deaths are due to the toxic action of mercury on the heart, and Long and Farah<sup>8</sup> have

<sup>3</sup> *J. clin. Invest.*, 1946, 25, 523.

<sup>4</sup> *Ibid.*, 1946, 25, 534.

<sup>5</sup> *Amer. J. Syph.*, 1946, 30, 420.

<sup>6</sup> *J. clin. Invest.*, 1946, 25, 547.

<sup>7</sup> *Ibid.*, 1946, 25, 557.

<sup>8</sup> *Science*, 1946, 104, 220.

<sup>1</sup> *British Medical Journal*, 1946, 1, 240.

<sup>2</sup> *J. clin. Invest.*, 1946, 25, 497.

shown that in the heart-lung preparation of the dog this effect of mercury can be antagonized by BAL. Although the heart after the mersalyl injection is in ventricular fibrillation the injection of BAL arrests the fibrillation, restores a normal rhythm, and re-establishes the blood pressure.

What may prove another important application of BAL is in the treatment of gold poisoning. The use of soluble compounds containing gold for the treatment of rheumatoid arthritis is always attended by the risk of the prolonged and painful reactions which gold produces in some patients. Ragan and Boots<sup>9</sup> have treated 5 patients with gold dermatitis by giving injections of BAL, and in 4 of these, in whom the dermatitis had existed for less than 2 months, the pruritus ceased and the rash cleared. The result of relieving the dermatitis, however, was that the symptoms of rheumatoid arthritis increased. Lockie, Norcross, and George<sup>10</sup> successfully treated with BAL patients in whom gold injections had produced thrombopenic purpura and granulocytopenia. Their recovery was said to be spectacular. It may well be that with this new protection against toxic effects gold therapy will become a less risky matter. Various other metals—nickel, cadmium, chromium, and antimony—produce toxic effects which have been shown to be antagonized by BAL in animals. It is reasonably certain that the antagonism will be displayed in the human subject also, and that cases of poisoning by these metals which occur in industry will be more effectively treated than hitherto.

The background of BAL is worth some comment, since its introduction is an excellent example of the fact that academic research, carried out with the sole object of extending knowledge, is very often found to have an unexpected practical application. Peters had previously made a special study of the biochemical changes when a deficiency of vitamin B<sub>1</sub> occurs, and had shown that in the brain of the pigeon there is a failure to oxidize pyruvic acid, or pyruvate. He found that there was a similarity between the effects of chronic arsenical poisoning and deficiency of vitamin B<sub>1</sub>, for in both there was polyneuritis, and therefore it seemed reasonable to examine the effect of arsenite on the pyruvate-oxidase system of the brain. Peters, Stocken, and Thompson<sup>11</sup> therefore began their experiments by adding arsenite to minced pigeon brain; they found it had little effect on the oxygen uptake until they added pyruvate. The arsenite was found to reduce the extra respiration due to pyruvate by half, and the conclusion was drawn that arsenic had an inhibiting action on certain specific enzymes, but was not a general poison. The subsequent investigation of the action of lewisite on the protein keratine derived from human hair (collected from the barbers' shops in Oxford) led to the conclusion that efficient protection against arsenic required a dithiol compound able to form a stable ring with the arsenical agent. The steps towards the discovery, which were many, were in steady sequence; there is no sign in the record of a stroke of luck or of some accidental assistance enabling the discovery to be made by some short cut. It is indeed an advance when the biochemist using minced brain or

skin slices can discover a remedy which achieves what one thought was impossible—not only to prevent a lewisite burn, but to remove all appearance of it after it has actually occurred.

## RENAL TUMOURS

Deming<sup>1</sup> has analysed a series of 82 cases of renal tumour admitted to the New Haven Hospital during the past twenty-three years. The important finding is that 19.5% were living at the end of five years, 14.6% at the end of ten years, and only 9.08% were free from disease after the ten-year period. There were 11 cases in the first decade of life, none in the second, and 60 in the fifth, sixth, and seventh decades. Classification of the tumours still presents considerable difficulty, and the clinical advantages of too fine a subdivision are not obvious. This series included 26 adenocarcinomata, 25 hypernephromata, 12 tumours of renal pelvic origin, 6 malignant nephromata, 3 sympathicoblastomata, 3 sarcomata, 2 embryonal carcinomata, and 5 benign tumours. Half the malignant nephromata (Wilm's tumours) and all the sympathicoblastomata appeared in childhood.

Accurate pre-operative diagnosis of the exact nature of cortical tumours is impossible, but where a renal tumour is suspected pyelography should be repeated at frequent intervals. Information as to the degree of fixation or mobility of the kidney may be obtained by clinical examination supplemented by radiological studies in the vertical and horizontal positions. Of these 82 patients 69 were subjected to nephrectomy, 4 had biopsy of the tumour with ligation of the ureter, and 2 had biopsy only. The other 7 patients were admitted shortly before death and necropsies were performed. Nephrectomy remains the operation of choice, with excision of the ureter in the case of pelvic growths. Extension of the growth into the renal vessels or even into the vena cava increases the technical difficulties but does not necessarily preclude nephrectomy. Irradiation has as yet little to offer in the treatment of renal tumours; radio-sensitivity is not yet predictable either clinically or pathologically. Ladd, of Boston, has given up irradiation in children, claiming that it is of little or no value. On the other hand, irradiation does reduce the size of the tumour in some cases and may make surgical removal easier. It may also cause the temporary disappearance of pulmonary metastases, especially those from hypernephromata and embryonic tumours, but the growths soon recur.

The most striking feature about the secondary deposits is their late appearance. Two patients in this series died of metastases more than ten and eleven years, respectively, after nephrectomy for hypernephroma. Those patients with sympathicoblastomata or embryonic carcinomata all died within the three-year period. Although in 36 cases there was no delay in making a diagnosis, and in one half of these the tumour was discovered during routine clinical examination, there was little difference in the ultimate fate of those cases subjected to early operation and those in which for some reason or other nephrectomy had been delayed. The outstanding feature of this survey is its demonstration of the fallacy of the five-year period in the control of renal tumours. The long delay in the appearance of metastases suggests that there may be body-defence mechanisms which play some part in controlling the course of these tumours—mechanisms about which we know nothing at present but which may prove important in explaining the slow growth of some malignant tumours.

## PENICILLIN AND DIPHTHERIA CARRIERS

The number of procedures advised for treating the diphtheria carrier state testifies to their limited value. Each is in fashion for a time, but few survive prolonged trial. When evaluating the divergent results obtained three factors must be borne in mind. In the first place it is probably true to say that we too often think of the carrier state as a mere surface infection, whereas of course the organisms often lie deeply in tonsillar and other tissue. Further, a common prerequisite of the carrier state is a diseased condition of the upper respiratory tract, which is unlikely to be affected by antiseptic applications. Finally, the undoubted importance of reinfection in prolonging the carrier state is now widely recognized. Macdonald,<sup>1</sup> for example, has recently drawn attention to the frequency with which skin and finger-nail infections are associated with anterior nasal diphtheria—a condition which might almost be classed with the carrier states.

Penicillin is the obvious modern remedy, for it has been noted by many workers—for example, by Young and Wood<sup>2</sup> and by Long<sup>3</sup>—that most strains of *C. diphtheriae* are sensitive to this antibiotic. The reports of the results of treatment, however, have not all been in agreement. Berman and Spitz<sup>4</sup> used a watery solution containing 500 units per ml., and, after instilling 1 ml. into the nose by means of a dropper, they administered 1 ml. atomized into the fauces and pharynx. This treatment was given four times daily for five days. Ten carriers so treated became clear after the first day and remained so; twelve controls, who were treated initially with hot saline gargles, remained positive until penicillin was used, when five promptly became negative. Paull and his colleagues<sup>5</sup> also used penicillin locally in nebulized form (2,000 units per ml. in 10% glycerin-saline). They gave four treatments daily, but concluded that no reduction in the duration of the carrier state was effected. Bagnall and Bain<sup>6</sup> used penicillin parenterally. Twenty-two of their cases received 0.6 mega-units and another 25 received 1.2 mega-units, both groups over a period of one week. The treatment was not always effective, but they found an association between failure and the condition of the tonsils, described as "bad" in 13 out of 14 failures in the first group and 6 out of 7 in the second. More recently Kocher and Siemens<sup>7</sup> have compared the effect of local and systemic treatment. Systemic penicillin completely failed to cure nine carriers. Local treatment with a gum lozenge, which took half an hour to melt and contained 500 or 1,000 units of penicillin, was more successful. One lozenge was sucked hourly for 12 waking hours over a period of 3–15 days. Of 31 carriers so treated 23 cleared rapidly, and cultures remained negative up to ten days after treatment was stopped. Seven of the remainder cleared after tonsillectomy, the eighth after both tonsillectomy and a further course of local penicillin.

What lessons can we learn from these conflicting results? Perhaps the first is to draw attention again to the unpredictability of the course of the carrier condition. The failure of systemic penicillin is disappointing, for one had hoped that this would sterilize the tonsil from within. Perhaps the difficulty here, as in the treatment of subacute bacterial endocarditis, is to ensure that the penicillin actually penetrates the barrier surrounding the organism. In considering the problem of local therapy we would draw

attention to three points. First, the dangers of local oral penicillin must be remembered, for stomatitis is a possible risk. Secondly, such treatment may merely mask the condition temporarily (Bagnall and Bain<sup>6</sup> cultured *C. diphtheriae* from the centre of a removed tonsil from whose surface before tonsillectomy eight consecutive negative cultures had been obtained). Finally, and perhaps most important, when the tonsils are obviously unhealthy surgical measures should be advised if penicillin does not rapidly clear them.

## VAGAL RESECTION FOR PEPTIC ULCER

In his Moynihan lecture, reported elsewhere in this issue (p. 540), Dr. Arthur W. Allen compared the results of subtotal gastrectomy with those following vagal resection. Resection of the vagi for the relief of the symptoms of peptic ulceration has been practised in America for several years. Dragstedt,<sup>1</sup> who re-introduced this operation, has recently reported a four-year follow-up on some of his cases. In this country vagal resection has not been widely adopted so far. Our patients are not yet so enlightened as is apparently the case in the States, where sufferers are said to approach the surgeon armed with a copy of *Time* describing vagotomy in lyrical terms.<sup>2</sup>

Physiologically there is sound support for this operation. Gastric secretion has a twin control: there is a hormonal phase evoked by food in the stomach, and a psychic phase centrally controlled through the vagus nerves. This latter mechanism is largely responsible for the hypersecretion which occurs in duodenal ulceration, and vagal section should therefore abolish it, with consequent benefit to the patient. Anatomically there are peculiarities about the vagus nerves which make it doubtful if it is ever possible to cut them completely. High in the thorax they give off filaments which penetrate the wall of the oesophagus and run down in it to the stomach. These fibres will clearly be untouched by any operation at the hiatus of the diaphragm whether approached through the thorax or the abdomen. Their number is not great, and it may be that their effect is negligible; but we would do well not to forget them entirely.

The immediate results of the operation are striking. Smith, Ruffin, and Baylin,<sup>3</sup> reporting 50 vagotomies with one death, claim that in 43 instances there was a complete recovery, the patients being able to eat an unrestricted diet and return to full work. Similar successes have been recorded by other workers. The side-effects of the operation are considerable and may require further surgery. Dilatation of the stomach occurs in all cases; it is least in those cases in which there has been a previous short-circuiting operation, but without this it may be extreme. Thus Smith and his colleagues had one patient in whom there was complete retention of barium in the stomach for forty-eight hours. The motility of the stomach is profoundly altered; peristalsis is not entirely abolished, but the waves are slower, more shallow, and less rhythmic. They may fail to constrict the barium in the stomach at all, but, according to Machella and others,<sup>4</sup> they can be restored by the injection of urethane of *N*-methylcholine chloride. Diarrhoea often appears when the patients start to eat a normal diet; there may be as many as ten watery motions a day accompanied by lower abdominal discomfort. The degree of hypochlorhydria which follows the

operation depends upon the completeness with which the accessible fibres of the vagus are severed. It can be estimated by some form of insulin test, and it would be an advantage if the precise procedures for the performance of this test laid down by Hollander<sup>5</sup> were adopted as a standard in the evaluation of these cases.

All those who have experience of the operation agreed with Dr. Allen that there are definite criteria which must be observed in choosing suitable patients. Thus Orr and Johnson,<sup>6</sup> who recently reported a series of 50 cases from the British Postgraduate Medical School, recommend that it should be restricted to duodenal or stomal ulcers, preferably in young subjects with a long history of relapses. They point out that the reduced gastric motility after operation may cause an unsuspected stenosis to come to light. If a pre-operative radiograph shows much scarring of the duodenum, then vagotomy will have to be combined with some form of short-circuit. Many years must elapse before any new treatment of peptic ulcer can be accurately evaluated. Of vagotomy now, it may be said that so long as suitable cases are carefully chosen it is likely to be a useful measure. But surgeons should bear in mind Sir David Wilkie's observation that any new operation is likely to give excellent results in its early days when patients are chosen with the utmost care. Later, when the operation is widely adopted and selection is less strict, results are often disappointing, and a useful procedure may fall into disrepute. It is to be hoped that this will not happen with vagotomy.

### THE R.C.S. AND THE SURGICAL CONGRESS

The International Surgical Congress concluded its proceedings in Edinburgh, an account of which we print elsewhere in this issue. The success of the Congress as a whole owes much to the President of the Royal College of Surgeons of England, Sir Alfred Webb-Johnson, who not only brought a message of welcome from His Majesty but through whose good offices permission was obtained to hold the inaugural ceremony in the picturesque Hall of Lincoln's Inn, thanks to the kindness of the Treasurer and Masters of the Bench.

Some of the famous visiting surgeons took home with them the Honorary Fellowship of the College; the recipients came from Belgium, France, and the U.S.A. The Lister medal was presented to Evarts Graham, of St. Louis, who has done so much to advance surgery in so many fields, and the honorary medal of the College to Edward Gallie, of Toronto. These awards were not presented in the privacy of the Council Chamber but *coram publico*, with all the ceremonial that befitted the occasion.

Thanks to Sir Alfred, the feast of surgical instruction for the postgraduate from London and elsewhere was prolonged for another ten days. The brilliance of the Congress week was followed by a series of lectures by masters of their craft, and the seating accommodation of the bombed College of Surgeons was strained far beyond capacity: on the Friday twelve hundred surgeons tried to gain admittance to hear Alfred Blalock, who saved the situation by giving a "repeat performance." The other lecturers were received with equal enthusiasm: Arthur Allen, Frank Lahey, Edward Gallie, Evarts Graham, Hassan Ibrahim, and Harold Wookey.

The Royal College of Surgeons, under the inspiration of its President, is fast becoming for surgical postgraduate

teaching and research a European centre of the first magnitude, and we look forward to seeing the events of the past fortnight recorded in the College's new journal.

### LAST YEAR'S HEALTH

The Social Survey in an investigation recently reported<sup>1</sup> found that the improvement noted in 1945 in the incidence of sickness was not maintained during 1946. The average monthly rate for minor sickness in both males and females was considerably above the rate for 1945 and slightly in excess of the 1944 rate. The incidence of more serious illness among males aged 16-64 in 1946 was of the same order as that for 1945; the rate for females showed a slight rise over the 1945 value. The rates for both sexes, however, were below the 1944 figures. The average number of serious illnesses among men aged 65 and over was slightly in excess of the number recorded in 1945; older women had an excess of 71%. The morbidity rate during 1946 for all forms of sickness at ages 16-64 declined from 7.5 per 100 persons in January to about 3.3 in the summer, and increased again to 6.0 in December. For females a larger average number of minor sicknesses was recorded than for males, but there was little difference between the sexes in the incidence of serious illness.

Attacks of influenza or colds were most common and were approximately twice as numerous in the age group 16-64 as in the over 65 group. A consistent excess of sickness from colds, influenza, and respiratory diseases occurred in the last three quarters of 1946 as compared with 1944 and 1945. Attacks of rheumatism also increased during 1946 among both sexes at all ages. Females aged 16-64 had a slightly larger average number of attacks of rheumatism than the males, but the latter were more incapacitated (7 days per 100 men, compared with 4 days per 100 women). In older people the average number of days of incapacity was more than double the number at ages 16-64.

There was no significant change during 1946 in the reported incidence of conditions thought to be of nervous origin. For the "psychoneurosis" group the monthly rates varied from 13.2 to 17.0 at ages 16-64; the rates for the older people followed a similar trend. The rate for functional digestive disorders varied from 7.7 to 10.3 for persons aged 16-64; older persons had a higher incidence. About one out of every three persons interviewed mentioned one of the "nervous" conditions as a cause of sickness.

The findings of the Social Survey confirm the experience of general practitioners that during last year minor ailments were on the increase. It will be of interest to learn what 1947 has to show. After the stresses and strains of a long war an increase in illness is hardly surprising, and it is unprofitable to attribute such increase to shortage of foodstuffs and other commodities. In comparison with any other country we can justifiably claim that what we have we share equally. But the sense of war-strain persists, and so long as it persists its effects will continue to be felt.

The Harveian Oration entitled "Our Founders and Benefactors" will be delivered by Dr. C. E. Lakin before the Royal College of Physicians of London (Pall Mall East, S.W.) on St. Luke's Day (Saturday, Oct. 18), at 3 p.m.

## DUODENAL ULCER

## DR. A. W. ALLEN'S MOYNIHAN LECTURE

At the Royal College of Surgeons on Sept. 22, as was briefly reported last week (p. 505), Dr. Arthur W. Allen, of Harvard, President of the American College of Surgeons, delivered the Moynihan Lecture, taking as his subject "Duodenal Ulcer."

Dr. Allen began by saying he had not chosen duodenal ulcer as a subject because of the pioneer work done by Moynihan, in whose memory the lecture was founded, for Moynihan, though he carried out important work in this field, had many other interests. He had chosen it because the subject was still in a fluid state. Ideas were constantly changing. No sooner did there seem to be an answer, or a probable answer, to some problem than doubt arose owing to the appearance of apparently contradictory results. Perhaps 10% of patients failed to get along under conservative treatment and came into the hands of surgeons who, after years of trial and error, thought that they had hit upon the solution in subtotal gastric resection. Although it was obvious that this operation was giving a high proportion of good results—a higher proportion than any other method

heretofore advanced—he himself began to have misgivings a few years ago. Some patients were not improved after the procedure, and there were a few who seemed to have been made worse. In an analysis of the gastrectomies he had carried out for uncomplicated duodenal ulcer it was obvious that a certain number of the patients had side effects which were perhaps worse than their original malady. Physiologists were continually looking for an explanation of this wayward situation arising in one patient when the previous nine and the following nine had

no trouble whatever, and they had turned to the question of hyper-secretion and hyper-acidity, without which ulcer of the duodenum did not occur.

In Dr. Phemister's clinic in Chicago, Dragstedt had brought forward the possibility of treatment of duodenal ulcer by interruption of the vagus nerve. He (Dr. Allen) had a group of his own patients who had been treated by subtotal gastrectomy and had been the subject of a follow-up extending over ten years. In his hospital there was also a group of patients who had been treated by vagus resection with a follow-up extending, however, over a much shorter period (about four years). It was his intention to show comparatively the results obtained in these two groups.

## Subtotal Gastrectomy

In the first place Dr. Allen with the aid of diagrams described the operation of subtotal gastrectomy for duodenal ulcer, with certain modifications to meet particular types of cases. The first procedure, which had been followed in the great majority of his own cases, was primary resection with removal of the ulcer-bearing portion of the duodenum. The second was one which he had found useful on occasion for any deep-lying ulcer

with adhesions; it was followed in cases in which there was a sufficient amount of free duodenum above the ulcer so that the resection could be done, the ulcer excluded, and nothing left which might produce a recurrence. A third possibility related to patients with very extensive ulceration or adhesions, who might perhaps have had a perforation previously, and on whom it was necessary to operate for mechanical reasons. Here a procedure was resorted to whereby the antrum was cul, the mucosa of the antral segment carefully removed, and the segment turned in. The fourth type of procedure was adopted in certain difficult cases when a two-stage operation seemed to be justifiable. Gastrectomy for exclusion was done, but no attempt was made at the time to remove the antral mucosa. Six weeks later, however, another operation was done on the patient for this purpose. The idea was that this made the operation a safe one for the general surgeon who was not carrying out gastric surgery regularly, and that the safeguard of a two-stage operation would mean a lower mortality and fewer complications. This operation had been undertaken quite extensively at the Massachusetts General Hospital, but he had seldom found it necessary in his own practice.

An analysis of his 196 consecutive operations on patients with uncomplicated duodenal ulcer, carried out according to the four procedures set out above, is given in the table below.

The mortality was mostly due to difficulty with the duodenal stump, because resection had to be done so low that there was no room to get an adequate turn-up. He had excluded from this list, in order to get a true comparison with vagus resection, those cases which had previously been the subject of unsuccessful surgery and those in the acute stage of massive haemorrhage. On the matter of age, even elderly patients who were bleeding from a

Sir Alfred Webb-Johnson, P.R.C.S., Dr. Dallas B. Phemister, Dr. Frank H. Lahey, Dr. Irvin Abell, Dr. Everts A. Graham, and Dr. W. E. Gallie. Dr. Arthur W. Allen, P.A.C.S., is at the lectern, which with the oak table was presented as a gift from the American College of Surgeons to the Royal College of Surgeons of England.

duodenal ulcer, if operated on immediately they got over the shock, would show a very low mortality. Actually in twelve patients who were over 65 there was only one death. But, of course, it was a question how much should be ascribed to the particular procedure followed and how much to the generally heightened level of surgery. Surgery in every field was far safer than it was ten years ago. Mortality rates were coming down, and death after operation in the modern hospital was now a rarity.

	(1)	(2)	(3)	(4)	Total
Cases .. .. .	138	20	35	3	196
Deaths .. .. .	3	1	0	0	4

## Vagus Resection

Dr. Allen proceeded to show further diagrams illustrating how the section of the vagus should and should not be done. A possible error was inadequate removal of the nerve. The procedure which should be followed was the removal of a 10 cm. segment, not less than 5 cm., preferably 10 cm., of the vagus nerve, and the encapsulation of the upper end in an impermeable cylinder in the hope that this might delay regeneration. All the cases at his own hospital had been operated on in

that way. They did not complicate their cases with gastroenterostomies. They had not carried out this operation for gastric ulcer for the very obvious reason that they were not able to determine whether the ulcer was benign; 14% of the cases diagnosed as benign ulcer of the stomach proved to be cancerous. Therefore vagus resection had no place in the surgery of gastric ulcer.

The statistics from his hospital for vagus resections carried out from 1944 to 1947 were as follows:

	Number of Cases.	Deaths
Duodenal ulcer .. ..	75	0
Jejunal ulcer .. ..	22	0
Miscellaneous .. ..	6	1

The 75 cases were of uncomplicated duodenal ulcer. The patients had undergone various forms of medical treatment. Most of them had been through the hands of the psychiatrist. Finally, when it became obvious that nothing could be done by those means, they were chosen for this surgical procedure because they had no obstruction at the outlet of the stomach or in the duodenum, and most of them were young. Twenty-two cases were operated on for anastomotic ulcer. These were the type of cases in which the procedure he had indicated had its most spectacular effect. This group of anastomotic ulcers could be relieved certainly temporarily by this method, and it was startling to see them awakened from anaesthesia free from pain for the first time for months. He added that the nerves should be injected with novocain before they were severed or manipulated, and the patients should receive large doses of atropine. He showed a radiograph illustrating the appearance twelve days after resection in a case in which there had been a good-sized jejunal ulcer, and many such results could be shown. There had been almost no trouble from empyema and complications of that kind. He also showed a curve illustrating the effect which the vogue of vagus resection had had upon the number of private patients coming to him and being treated by subtotal gastrectomy. The curve showed a certain fall during the years in which vagus resection had come into favour, but he added that they were not quite so enthusiastic now about vagus resection as they were at the beginning.

#### The Methods Compared

Dr. Allen next showed the result of a follow-up extending back for ten years in the cases of subtotal gastrectomy and four years in the cases of vagus resection.

	Subtotal Gastrectomy	Vagus Resection
Number of cases .. ..	196	75
Average age .. ..	47.4	42.1
Males .. ..	84%	84%
Recurrent ulcer .. ..	34%	14%
Good result .. ..	85%	87%
Fair result .. ..	7%	6%
Poor result .. ..	8%	7%
Operative mortality .. ..	2%	Nil

These were all cases of primary duodenal ulcer. In his own group of subtotal gastrectomies he was ready to claim that 85% showed satisfactory results. Many of the patients had to be questioned very closely to get much in the way of symptoms out of them. The results described as "fair" were those in which the patient was not quite well, was subject to restrictions in diet, and, if not actually showing loss of weight, had to be the subject of considerable attention in order to maintain weight.

The drawbacks attaching to subtotal gastrectomy for duodenal ulcer were a certain though very small operative mortality, a number of cases of anastomotic ulcer, a few cases of gastritis with bleeding, the exhibition occasionally of the "dumping syndrome" (in which there were distress, sweating, and sometimes nausea after eating—but most patients got over it), a certain amount of weight loss which was a problem with some of the older patients, and a gastro-intestinal reflex indicated by loose stools and the like.

Vagus resection had also the drawback of occasional recurrent ulcers. It was hard to say after what period recurrences were no longer to be expected. In his hospital, for example,

one-third of the anastomotic ulcers which followed operation occurred within the first year, another third within the second year, but the remaining third were spread over a period of many years. Therefore it was difficult to use the term "end result," and perhaps it should never be used in a situation of this kind. Two of the patients who had undergone vagus resection had persistent ulcer pain after the operation as well as before it; some had pain and bleeding; others had a feeling of distension; eructations were almost the rule, though this was usually transient, and diarrhoea and slight obstruction were not infrequent.

#### Conclusions

This entire problem should be viewed with an open mind. Vagus resection was a useful procedure and might have a permanent place in the treatment of duodenal ulcer. But unless the results were critically analysed, not only of vagus resection but of subtotal gastrectomy, their colleagues who had not the opportunity of following up a group of cases over a sufficient period would be misled. Either an adequate subtotal gastrectomy or vagus resection would give a high incidence of immediate relief in intractable duodenal ulcer. Vagus resection was the procedure of choice in anastomotic ulcer following upon subtotal gastrectomy. It was also to be recommended in intractable duodenal ulcer in younger patients. Vagus resection had no place in the treatment of gastric ulcer on account of the difficulty of distinguishing benign from malignant ulceration of the stomach, and because of the excellent results and low mortality obtained by gastric resection in gastric ulcer. In vagus resection the transthoracic approach was the most adaptable for an interruption of the efferent pathway. Obviously many years of experience and careful selection of patients and adequate follow-up would be necessary properly to evaluate vagus resection. Subtotal gastrectomy was, in his opinion, to be preferred for all patients who had superficial obstruction from duodenal ulcer, for those with acute massive bleeding when any operation was indicated, and for those with intractable ulcer in the later age groups.

(See also an annotation on this subject at p. 538.)

## INTERNATIONAL SOCIETY OF SURGERY

### VISIT TO EDINBURGH

Following the Twelfth Congress of the International Society of Surgery in London, about 160 members of the Society visited Edinburgh from Sept. 23 to 26. A comprehensive and detailed programme arranged by the Department of Surgery of the University of Edinburgh included a wide choice of operating sessions at many of the voluntary and municipal hospitals in the city, and special demonstrations at the University departments of surgery and anatomy. The library and museum of the Royal College of Surgeons of Edinburgh were also open to members of the Society throughout their visit. On Tuesday morning Prof. J. R. Learmonth extended a cordial welcome to the visitors. Later a number of members were present as guests of His Majesty's Government at lunch in the Caledonian Hotel, under the chairmanship of the Rt. Hon. Joseph Westwood, M.P., Secretary of State for Scotland. In the afternoon the scientific sessions began.

#### Treatment of Thyrotoxicosis

Prof. D. M. Dunlop presented a study of 76 consecutive cases of thyrotoxicosis treated with thiouracil over periods varying from one to three and a half years. The initial dosage was 0.6 g. daily, for three to four weeks, followed by maintenance doses of 0.05 to 0.2 g. daily. Overdosage caused myxoedema and increase in the size of the goitre. The results in 66 of the cases were comparable to those following successful thyroidectomy. Drug resistance was encountered in 4 cases and required thyroidectomy, which was also performed with good results in 5 out of 6 cases showing toxic reactions to the drug. Of 43 patients in whom treatment was stopped after about a year, 13 had remained free of symptoms for one to three years. The other 30 had relapsed at varying periods after stopping the

drug, but further treatment had again controlled them. Thiouracil was the treatment of choice in young people with primary thyrotoxicosis, excluding those with sternal goitre, pressure symptoms, or possible malignancy.

Mr. K. Paterson Brown said that since the introduction of thiouracil the number of thyroidectomies performed in Edinburgh had been markedly reduced. In pre-operative preparation the ideal was thiouracil for a month followed by iodine for ten days. Among the indications for operation in primary toxic goitre were non-control of symptoms by thiouracil, increasing size of the thyroid and pressure symptoms, the desire of the patient for operation, and complications produced by thiouracil treatment. In secondary toxic goitre operative treatment was considered preferable, as pressure symptoms were often present, there was lessened danger of later cardiac breakdown, and there was the possibility of malignant change developing. Complications of surgical treatment were uncommon, but the danger of post-operative haemorrhage was stressed.

#### Treatment of Haemorrhagic Diseases

In a symposium on this subject the medical aspects were presented by Prof. L. S. P. Davidson and his associates, and the surgical aspects by Prof. J. R. Learmonth.

**Thrombocytopenic Purpura.**—The essential features of the idiopathic type consisted of a bleeding tendency, associated with a low platelet count, a prolonged bleeding-time, increased capillary fragility, and an increase of megakaryocytes in the bone marrow. The indications for splenectomy were: chronic cases in which the bleeding tendency interfered with social or economic efficiency because of anaemia, or endangered life; acute cases in which conservative treatment failed to control bleeding; and cases with evidence of intracranial haemorrhage. The operation should not be performed on a child until medical treatment had been given a thorough trial, or when the condition was not idiopathic, or when there was evidence of spontaneous remission. In 10 cases submitted to splenectomy the clinical results were good, even where a prolonged bleeding time, a low platelet count, or increased capillary fragility recurred.

**Haemolytic Anaemia.**—The essential features were a persistent or recurrent anaemia with increased or normal red cell fragility, increased reticulocyte count, normal colour index, normoblastic bone marrow, and, frequently, microspherocytosis. The spleen was moderately enlarged, and haemolytic crises might occur. Indications for operation were the occurrence of symptoms in childhood, the formation of biliary stones, the recurrence of a crisis, or failure of a crisis to respond to blood transfusion. Of 7 patients who underwent splenectomy 6 now showed no evidence of anaemia.

**Banti's Syndrome.**—This might be due to intrahepatic (cirrhosis) or to extrahepatic (obstruction in the portal or splenic veins) causes. Cases might be subdivided into those suitable for medical treatment (mild cases without oesophageal varices); those suitable for splenectomy, where the block was in the splenic vein; those suitable for ilio-renal or porto-caval anastomosis, where the block was in the portal vein or in a liver only moderately damaged; and those not suitable for operation—cases of advanced cirrhosis with impending death from hepatic failure. Insufficient time had elapsed to assess the results in the 7 cases which survived operation.

**Doubtful Cases.**—There was a group of cases refractory to liver and iron therapy which might simulate haemolytic anaemia in that the colour index was about unity, the marrow hyperplastic and normoblastic, and the reticulocytes slightly increased. Cases of hyper-splenism had been described in which the spleen was believed to prevent the final maturation or expulsion of red cells from the marrow. For this reason splenectomy was justifiable in this group when all other measures had failed.

#### Carcinoma of the Breast

Dr. R. McWhirter presented a paper based on the study of 2,500 cases of carcinoma of the breast carefully followed up (with only 6 untraced). In a series of 364 cases of operable breast cancer treated by radical surgery alone, 39% developed recurrences in the operation area within five years. Radiotherapy after radical operation reduced this figure to 14% but

only succeeded in raising the five-year survival rate from 35.6% to 44%. In 1941 it was decided that the operation should be restricted to simple excision of the breast and that the axilla should not be dissected. By so doing it was hoped that cells would not be disseminated outside the area which could be treated by radiotherapy. In the period 1941–5, this method was used in 942 operable cases and the five-year survival rate had been raised to 56%. In "inoperable" cases treatment by radical surgery and radiotherapy gave a five-year survival rate of 2.5%, which by simple mastectomy and radiotherapy had been increased to 14.1%. When cases with clear clinical or radiological evidence of distant metastases were excluded, the five-year survival rate in the "inoperable" group treated by simple mastectomy and radiotherapy was 24.6%, and perhaps this figure brought out more clearly the value of the method now in use. In 1,146 cases of breast cancer without clinical or radiological evidence of distant metastases treated in the period 1941–5 the first-year survival rate was 50.1%. In the operation of simple mastectomy performed before radiotherapy no iodine should be applied to the skin and no adhesive plaster used, a both lowered the skin tolerance. The scar should be as short as possible, and not extended into the epigastrium. To avoid tension too much skin should not be excised even if this meant leaving diseased skin for later irradiation. The axilla should not be dissected. (In very stout patients radical operation might be necessary owing to the technical difficulty of x-ray treatment.) The supraclavicular glands should never be removed as they were very accessible to irradiation. In the subsequent radiotherapy only one full course should be given, about two weeks after operation. The axillary and supraclavicular glands were treated as one chain, and the chest wall was treated in large tangential fields. Routine irradiation of the ovaries in all patients over 35 years was advocated.

#### Curare in Anaesthesia

Dr. John Gillies, in an assessment of the value of *d*-tubocurarine chloride as an adjuvant in anaesthesia, gave a brief historical survey from the description by Sir Walter Raleigh in 1595 of the use of curare as an arrow poison by the Orinoco Indians to the isolation of the pure alkaloid by Harold King in 1935. The mode of action was by preventing acetylcholine from acting on the nerve-muscle junction in the motor end-plate, thus producing paralysis of striped muscle. The drug was partially destroyed by the liver and excreted by the kidneys. He compared 100 consecutive personal cases in which *d*-tubocurarine was used with the same number in which it had not been employed. The advantages of the drug were in the quality of relaxation, particularly in difficult upper abdominal surgery, and the reduction of toxic effects due to the saturation of tissue cells by the general anaesthetic, particularly in ill patients. The dangers were "paralytic" apnoea, inadequate CO<sub>2</sub> clearance, and anoxia; secondary circulatory effects; bronchospasm and atelectasis; and passive reflux of gastro-intestinal contents and their aspiration. The incidence of serious post-operative respiratory complications was decreased by the use of curare.

#### Peptic Ulceration

Prof. C. F. W. Illingworth, discussing the prospects of treatment in peptic ulcer, stated that subtotal gastrectomy was not uniformly effective. The mortality was still too high, and careful follow-up studies showed poor results in a proportion of cases. The great and increasing frequency of peptic ulcer (there were nearly a million cases in Great Britain), emphasized the need for a wider approach to the problem, including the medical, surgical, social, and psychological aspects. Essentially the three main principles underlying treatment were: to control the acidity of the gastric juice, to protect the mucous membrane from its activity, and to put the ulcerated part at rest. Vagotomy might be expected to reduce the hypersecretion and diminish gastric motility; but experience with the sub-diaphragmatic operation had been disappointing, and it remained to be seen if the supra-diaphragmatic method would prove more successful. There seemed to be scope for exploration of the effects of drugs which paralysed the parasympathetic endings and for the use of anti-histamine substances. The importance of after-care was stressed.

Mr. W. Quarry Wood, describing the treatment of peptic ulcer by ligation of the gastric blood vessels, reviewed a personal series of 42 cases treated by T. Howard Somervell's method of ligation of four-fifths or five-sixths of the gastric blood vessels, with the addition of gastro-enterostomy. First impressions were reasonably satisfactory, with in most cases a return to full work and considerable gain in weight. But three cases developing stomal ulceration and coming to subsequent operation showed the development of fresh vessels on the lesser curvature. It was also found that there was no permanent reduction of acidity. No criticism of Wilson Hey's method was implied, as this was fundamentally different in principle.

Mr. A. G. Ross Lowdon discussed the surgical treatment of 15 cases of gastro-jejuno-colic fistula—which might develop at any time up to twenty years or more after gastro-jejunostomy. The symptoms were characteristic, with severe diarrhoea (due to jejunitis caused by the contents of the colon entering the small intestine), cructations of foul gas, vomiting of faecal matter, and wasting. Treatment was by a two-stage operation, preferably a proximal transverse colostomy followed by partial gastrectomy with reconstitution of the jejunum and transverse colon.

#### Other Contributions

Mr. David Band discussed the restoration of vesical continence and the rehabilitation of patients suffering from spinal cord injuries. Treatment by resection of the hypertrophic muscle at the bladder neck to provide a wide channel from the bladder to the prostatic urethra, and by tidal lavage against an increasing pressure to increase bladder capacity to approximately normal, had resulted in a restoration of normal evacuation of the bladder, with complete continence between acts of micturition.

Mr. D. M. Douglas, describing two experiments in the study of the rhythmic activity of the small intestine in the dog, deduced evidence to suggest that there was a pace-making mechanism in the upper part of the small intestine.

Mr. A. J. Slessor, in a review of 22 cases of causalgia, defined as a "spontaneous severe pain of 'burning' character situated approximately in the sensory territory of a nerve which has been injured," described the immediate results of sympathectomy as satisfactory, and stated that the beneficial effect of sympathectomy lasted over a period of at least three years.

Prof. W. C. Wilson described the study of 30 cases of severe peritonitis, of which 12 were fatal, by serial estimations of plasma and blood volume, total circulating protein, albumin, and haemoglobin. The usual changes were a reduction of plasma volume to a level as low as 60% of normal, a parallel reduction of total circulating protein, and a disproportionately great reduction of total circulating albumin. These changes were mainly due to the exudation of whole plasma into the peritoneal cavity.

Mr. T. McW. Millar, referring to tumours of the recto-sigmoid region which were too low for resection and end-to-end intra-peritoneal anastomosis, or for the Paul-Mikulicz operation, presented the argument for adoption in selected cases of anterior resection with immediate end-to-end anastomosis, with or without preliminary colostomy, and discussed the problems involved. The standard method of treatment by the abdomino-perineal operation of Miles left the patient with a permanent colostomy. He asked, Was the sacrifice of the lower rectum and anus necessary?

Mr. A. W. Wilkinson presented a study of protein metabolism after gastrectomy and after operations on bones. Protein hydrolysates were given by the oral and intravenous routes. Oral hydrolysates had proved of limited value before operation, and after operation they were undesirable. Post-operative intravenous hydrolysates were given without adverse reaction, but it was found impossible to abolish the katabolic phase.

Prof. J. R. Learmonth in a succinct paper summarized the pathology and the possibilities of surgical treatment in the relief of portal hypertension.

#### Close of Meetings

When the final paper had been presented the visiting surgeons and their ladies assembled in the surgery lecture theatre to hear messages of good will and farewell from Edinburgh's senior professional and civic representatives. Sir John Fraser, Principal

of Edinburgh University, said that the value of such a congress could not be overestimated. Scotland had its own individuality and culture, with particular pride in its medical institutions and historic figures, and he felt that what had been presented by Prof. Learmonth and his colleagues suggested that the days to come would be no less distinguished than those which had gone before.

Sir George Anderson, Secretary to the Department of Health for Scotland, said that they had watched the congress with great interest, and had been proud to see its success and to hear the many tributes to the way it had been organized. Mr. J. M. Graham, President of the Royal College of Surgeons of Edinburgh, in saying farewell, said how much they had appreciated meeting and exchanging views with surgeons from other parts of the world, and asked that the younger surgeons should be encouraged to exchange visits, as it was on the younger men that the future of surgery depended.

Sir John Falconer, Lord Provost of Edinburgh, hoped that the visitors had sensed a real welcome in Edinburgh. Dr. L. Dejardin (Brussels), Secretary General of the International Society of Surgery, thanked the speakers on behalf of the visiting members of the Society for their good wishes, and expressed appreciation for all that had been done to entertain and instruct them, saying that the meeting would remain in their memories as a model of perfect organization.

#### Receptions

In addition to the scientific programme very full arrangements were made for the entertainment of the guests, both at public functions and by private hospitality, with whole-day tours of the Trossachs and the Scott country. On Tuesday evening a reception was held in the Surgeons' Hall by the President and Council of the Royal College of Surgeons of Edinburgh, at which the Diploma of Honorary Fellowship of the College was conferred on Prof. Jean Verhoogen, of Brussels, President of the International Committee of the Society of Surgery. In presenting him for the honour, Prof. R. W. Johnstone, vice-president of the College, referred to Prof. Verhoogen as the beloved doyen of surgery in Belgium, who throughout a long life spent in the practice of surgery had devoted himself to the highest service of his profession.

On Wednesday afternoon the visitors were received by Lord Provost Sir John Falconer and the Magistrates and Councillors of the City of Edinburgh at the City Chambers, where they were entertained to tea, followed by a spirited display of Highland dancing and piping by the Edinburgh Police pipe band.

In the fine spacious library of the University Old College, members of the Society were welcomed on Thursday evening by Prof. Sydney Smith, Dean of the Faculty of Medicine. Sir John Fraser, Principal of the University, who was unable to attend owing to illness, sent a message of welcome, to which Prof. Sydney Smith added his good wishes and a plea for the free exchange of scientific knowledge. In reply Prof. Verhoogen expressed the appreciation of the Society for the invitation to visit Edinburgh, and for all that had been done for their enjoyment.

#### ROYAL SHEFFIELD INFIRMARY

##### 150th ANNIVERSARY

The Sheffield General Infirmary was opened on Oct. 4, 1797. The occasion was marked by a truly "Grand Procession," headed by "Two Trumpeters, on white Horses, dressed in white," and ending up with the "Masters, Wardens, Assistants, and Members of those most useful Institutions the Benefited Societies, or Sick Clubs, as they are commonly called, preceded by different coloured Silk Flags." In the evening there was a dinner—"Ordinary and Extraordinary"—at the Angel Inn, for which the tickets were 7s. 6d. each.

The opening ceremony 150 years ago marked the fulfilment of a suggestion made eight years previously by Dr. William Younge (1762-1838). Dr. Younge was the son of a noted Sheffield physician. He took his medical training in Edinburgh and returned to his native town at the age of 25 "full of ability, energy, and large-heartedness." After two years in practice he

was so impressed by the need for hospital accommodation in the city that he wrote a pamphlet on the subject, signed it "X," and had 300 copies printed and distributed. One lady, a Mrs. Fell, was moved to give £1,000 towards the project, but it was three years before a town meeting was called "to inquire into the propriety of establishing an infirmary." Then it is possible that the apathy would not have been overcome but for the announcement of Mrs. Fell's gift. Supporting Dr. Younge in his campaign to get a hospital set up was Dr. John Browne (1740-1810). When Dr. Browne died the whole town went into public mourning.

One method of raising money for the hospital in the early days was to give benefit performances at the theatre. That on Monday, Nov. 27, 1797, must certainly have attracted the people, for the programme included "The Wonder"—a cryptic title which was explained by the subtitle, "A Woman Keeps a Secret."

Among those connected with the infirmary during the 19th century was Dr. Meriano Martin de Bartolome, who was President of the British Medical Association when it met in Sheffield in 1876. He was a native of Segovia and came of an old Castilian family. He moved to Sheffield after his marriage to a Sheffield lady and went to Edinburgh to study medicine. His successor as president of the medical school in Sheffield, Mr. William Fisher Favell, also took a prominent part in the B.M.A. Annual Meeting in Sheffield in 1876; his uncle had been President of the Association when it met there in 1845.

With the growth of specialist services in the infirmary an eye ward was set aside in 1823; the ophthalmic department was enlarged and a specialist appointed in 1877. In 1870 arrangements were made for the isolation of "contagious diseases and offensive surgical cases." In 1924 more beds were added for the ear, nose, and throat departments and the dermatological clinics.

The Sheffield General Infirmary acquired the title of Royal in 1895. It has naturally been associated with medical teaching in the city. In 1832 the existence of two medical schools led to the foundation of a rival hospital. One of the medical schools came to an abrupt end in 1835, when it was sacked and burnt by an anti-resurrectionist mob. The two hospitals were not united until 1939, when by Act of Parliament the Royal Infirmary and the Sheffield Royal Hospital became one corporation "to be called the Royal Sheffield Infirmary and Hospital."

## FUTURE OF VOLUNTARY HEALTH INSURANCE

As a result of the transference to the Ministry of National Insurance of the administration of cash sickness benefits and the establishment of a National Health Service under the Ministry of Health providing comprehensive medical service for the entire population, the voluntary health insurance movement in this country, as represented by the approved societies, is facing the most serious problem in its history. It is evident that the area left to voluntary health insurance will be narrow, and that many plans which had been established for the benefit of the low-income groups not covered hitherto by a compulsory system will have to be abandoned. The cutting off of the State insurance side of friendly society administration will mean a great reduction of income, estimated at approaching £2,000,000 per annum, not entirely met by the relief from liabilities, and many of the societies will also be faced with difficulties owing to the transference of some of their experienced officers to the national administration. According to a return, which is incomplete, made to the Conference of Friendly Societies at Margate in September, the voluntary insurance membership at the end of 1946 was 6,465,808, and the membership on the State insurance side 6,742,719.

A long and well-informed article on voluntary health insurance in Western Europe, which occupies the greater part of one of the recent *Public Health Reports* of the United States Public Health Service,<sup>1</sup> enables a comparison to be made between the position in Britain and in five other countries—France, Belgium, Sweden, Denmark, and the Netherlands. In all these countries voluntary health insurance originated

with the mediaeval guilds, and as these guilds passed out of existence the members of the community formed self-governing societies to provide sickness benefits as well as other types of mutual assistance. The friendly societies in Great Britain were the first to be encouraged in their development by the Government—this took place at the end of the 18th century—and were offered legal status and exemption from various types of taxes. During the 19th century a similar development took place in all the other countries. Down to the outbreak of the recent war the history of these societies was marked by increasing membership, the formation of larger units, widening scope of medical benefits, increased public supervision and control, increased availability for actuarial purposes of significant information on the incidence and duration of sickness, and, in Great Britain and the Netherlands, the emergence and expansion of special voluntary plans for medical and hospital services and home nursing. Denmark was the only country in which health insurance provided medical and hospital benefits for nearly all persons in the population.

The same development of social security programmes as Great Britain has seen since the war has taken place in one form or another in other countries. Denmark continues to administer its health insurance through approved mutual benefit societies. Sweden and Belgium retain the societies to administer their compulsory national health insurance systems. The Netherlands in its compulsory programme retains separate agencies for sickness and medical benefits, but the medical benefits are still administered through approved societies. France has created provincial and regional quasi-Government agencies to administer health insurance and other benefits within designated areas. In Great Britain, as already stated, approved societies will no longer participate in the national programme, and consequently considerable changes may be expected in the type of benefits the societies continue to offer through voluntary health insurance. Some of the smaller societies may be absorbed, some of the schemes be federated or consolidated. An idea has been put forward for the national amalgamation of provident schemes and similar plans to serve that section of the community which will prefer to make its own arrangements for hospital and other medical services. The spirit of the friendly societies is not easily broken, and intensive planning is taking place to meet a situation which the societies have accepted only under protest and with a feeling that their contribution to this field of endeavour, extending in the case of some of them—the Manchester Unity, for instance, and the Ancient Order of Foresters—for well over a century, has had scant reward from a Government which might have been expected to have treated them differently.

## TRAVELLING FELLOWSHIPS IN MEDICINE

The Medical Research Council announces that it has awarded Rockefeller Medical Fellowships to the following for the academic year 1947-8: Kenneth Robson Hill, M.D., Lecturer in Pathology, King's College Medical School, University of Durham, and assistant pathologist, Royal Victoria Infirmary, Newcastle-upon-Tyne; John Ivor Pulsford James, M.S., F.R.C.S., honorary assistant surgeon, Royal National Orthopaedic Hospital, London; Hamish Nisbet Munro, M.B., Ch.B., senior lecturer in physiological chemistry, University of Glasgow; John Eric Richardson, M.S., F.R.C.S., surgical first assistant, London Hospital; Harold Scarborough, Ph.D., M.B., Ch.B., Beit Memorial Research Fellow, Medical Unit, St. Mary's Hospital, London; Sheila Patricia Violet Shrock, M.D., Beit Memorial Research Fellow and assistant lecturer, Department of Medicine, British Postgraduate Medical School, London; Honor Vivian Smith, M.B., B.S., research assistant, Departments of Neurosurgery and Neurology, Radcliffe Infirmary, Oxford.

The Council has also awarded Dorothy Temple Cross Research Fellowships in Tuberculosis to the following: Alfred Gordon Heppleston, M.B., Ch.B., assistant lecturer in pathology, Welsh School of Medicine, Cardiff; Doreen Nightingale, M.S., F.R.C.S., first assistant, Surgical Unit, University College Hospital, London; John Robertson Sinton, M.B., B.S., late medical first assistant, London Hospital Annex, Brentwood.

## Correspondence

### The G.M.C. and Medical Education

SIR,—Sir Herbert Eason's helpful exposition on the functions of the General Medical Council (Sept. 6, p. 359) provides much food for reflection on a topical subject—medical education. To enable persons requiring medical aid to distinguish qualified from unqualified practitioners is the duty of the G.M.C. Does it not fail, virtually, in this primary object by leaving the British public at the mercy of rampant quackery in the form of ubiquitous and alluring advertisements of articles alleged to provide health or cures of disease? Furthermore, the public (and G.P.s) also lack any sure guide to enable them to distinguish the genuine and spurious specialist within the profession. The definition of a "specialist" is long overdue. Professional efficiency and the public weal will be served by restricting the title to one with a *guaranteed* minimum special ability in his section of healing.

*The Education of the General Practitioner.*—Under this heading the President alludes to three principles which prevent the Council, he says, following the lead of the Goodenough report. The interpretation of these principles seems open to question. "The Council must deal with things as they are"—i.e., a C3 nation. Granted this, we must begin at the root of the health problem—the student's curriculum—and surely the situation calls for drastic changes like those in the Goodenough report. It wants to "avoid completing after qualification incomplete instruction given before qualification." This ideal is well served by simplifying the instruction so that its inculcation in a complete form is practicable. Thirdly, the Council holds that instruction in the essentials must be adequate before the final examination. Yet to subjects of the curriculum it is recommended that new ones now be added. Since the total time is not increased, this means that something must be discarded of what was formerly regarded as essential, in order to make place for the new. The Council's judgment of essentials is shown to be changeable and open to argument.

*A New Concept of the G.P.*—With doubts about the effective safeguarding of the people's health it is well to review the Council's proviso regarding "things as they are" and their remedy. The G.P. is still, when health troubles arise, the beacon light on life's journey. More than ever there is room for this "guide, philosopher, and friend," but the time has come for an entirely new concept of his role in the body politic. The old legend on the brass plate of "Physician and Surgeon" is purely historical. Not only do medicine and surgery, but each of many further subdivisions, now call for separate devotees—the *specialists*—making ever sharper the contrast with the *general practitioner*. Of our growing medical knowledge a specialist knows more and more about less and less. The G.P. must know inevitably less and less about more and more; he alone maintains responsibility for the whole patient.

Think of the present preparation of the young doctor who has to assume this responsibility. His spirit as a student, confronted with mountains of medical science (of which little plays any part in daily practice), is apt to be cowed. He only learns the bulk of medical facts in order to get through examinations, and inevitably forgets it a few months after. What humbug still to inflict what has become so detailed and specialized in anatomy, physiology, pathology, forensic medicine, and the rarer diseases of medicine, operative surgery, and so forth. The student of humanity needs mainly to handle patients, be confronted with the stark facts of necropsies, and feel that what is taught is not merely highbrow but repays thorough mastery. Instead of being an exhausted wreck with an inferiority complex he will, on qualifying, feel confident, alert, lively, and "ready for the fray," albeit conscious of his limitations and unashamedly ready to seek the aid of the specialist.

*Realism in Relation to Daily Practice.*—First, there are common ailments that mar the health of the majority. On the eradication of these he wants to be brilliantly informed, yet they are largely ignored by "things as they are" in the curriculum. I refer to poor physical tone, mental imbalance, dental decay (87% of our best young manhood which went to France in 1939 needed dental treatment, and 12% required dentures), dyspepsia, constipation, diagnosis of cancer, rheumatism, feet deformities, etc. Secondly, there are those disorders that assail the public with relative infrequency, the importance of which his training tends relatively to magnify. Most of these are amenable to domiciliary treatment, and he needs to be not only conversant with but to acquire full competence in this, his proper sphere of therapy. Why does the Council not insist on at least one year's assistance with a reputable G.P. before independent practice is allowed? In the other subsection of the occasional ills—those more formidable enemies of the race requiring

specialists—the G.P.'s vital role is early recognition or shrewd suspicion that something serious is afoot calling for timely dispatch of the patient to the fountain-head. His concern is the deviation from health, not the minutiae of pathology. Instead, with educational "things as they are," the keen student tends to become a general pseudo-specialist. Knowledge of what health is, understanding, sympathy, and tact come not from books but by constantly being concerned with patients. What a brilliant example of this clinical approach to sickness is supplied by Sir Heneage Ogilvie's article on the "Early Diagnosis of Cancer of the Oesophagus and Stomach" (Sept. 13, p. 405). How little details of pathology and treatment figure therein, but the address reeks of humanity.

Take rectal cancer. It comes late, having been treated for many months as piles or dysentery, etc. The students needs to be taught the paramount importance of putting a finger well up the rectum in every case—i.e., regardless of the complaint of or the presence of piles. Directly the parts feel unnatural he seeks the expert's opinion. And so with the slightest doubt in the breast, with haematuria, etc. Yesterday (Sept. 15) I found a cancer crater extending up into the rectum from the verge of an external pile mass. All the laconic note on the case sheet (Jan. 13, 1947) said was, "Haemorrhoids. for operation." Today a lady in the late 30s came with a few months' pain p.c., some vomiting, wasting, and bringing radiological evidence regarded as that of leather-bottle stomach. It had been put down as gastric cancer. Examination below had been deferred because of menstruation. I examined her and found a fixed, encircling growth of mid-rectum. Think of the "acute abdomen." Here the patient relies on the G.P. for an unerring sense of something surgical amiss to save fatal delay. Again, it is not so much details of pathology, but a definition of the threat of peritonitis, obstruction, haemorrhage, and so forth that the G.P. needs to recognize. Only several months' residence in hospital covers the necessary familiarity with this problem of daily practice.

The curriculum needs to be cleared of the masses of academic jargon and injected with more about the common roots of ill-different health. At the same time, by cutting the total curriculum down to 5 years, the doctor is early launched into assuming responsibility for his patients. It is then his ambition is fired and his energies readily mobilized. He quickly acquires practical knowledge safely as an assistant still under the eye of his seniors, spending one at least of the next three years with a reputable practitioner. "You can't get the terriers too soon at the rats," said Sir Robert Hutchison.—I am, etc.,

Bristol.

A. WILFRID ADAMS.

### Disseminated Sclerosis

SIR,—With reference to the annotation entitled "On the Track of Disseminated Sclerosis" (Sept. 20, p. 460), I feel the following facts should be placed on record. The incidence of four cases of disseminated sclerosis in a group of seven laboratory workers engaged in studying the aetiology of a disease in sheep is an event which must arouse sympathetic regret but cannot occasion surprise. What does surprise me is the statement of the writer of the annotation that "chance has now thrown up an entirely new approach to the problem. . . ." While I agree with the writer that this may "open the way to a complete understanding of the cause of disseminated sclerosis and perhaps to its prevention and even cure," I would like to point out that the previous literature on this specific subject is completely ignored.

In a communication to the Association of Physicians of Great Britain and Ireland (published in the *British Medical Journal*, 1927, 2, 13) I referred especially to the occupational incidence of disseminated sclerosis and placed particular emphasis on farming. I then indicated that this was a channel into which inquiry might profitably be directed. The unanimity with which I was attacked convinced me of the probable accuracy and truthfulness of my observation. In 1921, Dreyfus, H. (*Z. ges. Neurol. Psychiat.*, 1921, 73, 479, emphasized the fact that the disease predominates among country dwellers in his analysis of 1,151 cases, a statement which I confirmed from my own experience (*Glasg. med. J.*, 1923, 100, 297). Boyd's *Pathology of Internal Diseases* (4th edition, 1944, p. 774, Philadelphia) refers to these observations by Dreyfus and myself, and S. A. Kinier Wilson (*Neurology*, 1940, 1, 150, London) also records my observations on this subject. Under my direction clinical

investigation has been continued over a long period of years into various aspects of the problem, including particularly the occupational incidence of the disease, with special reference to farming. It is hoped that the results of this work on a series of 389 cases of disseminated sclerosis will shortly be embodied in a paper by a member of my staff.

Your annotation refers optimistically to the prospects of discovering the cause and prevention of this illness. At the moment I personally feel that the detection of the mode of transmission is the next most valuable step that could be made, and there is a reasonable prospect that we are approaching this state of knowledge. In 1923 I made the following statement (*Glasg. med. J.*, 1923, 100, 290): "A still further advance may then be hoped for in the detection of the mode of transmission and prevention of infection in the individual."

It cannot be assumed that the causal agent of disseminated sclerosis will produce pathological changes in the nervous system of susceptible animals identical with those found in the human subject. Equally it cannot be assumed that infection by the same agent will necessarily result in identical tissue reaction in animals of different species. As an example of this important general principle, the causative agent of "loupings ill" is known to produce a separate histological picture in sheep, pigs, and mice (Brownlee, A., and Wilson, D. R., *J. comp. Path.*, 1932, 45, 67). Past experience has shown that this is an essential difficulty in attempting to transmit disseminated sclerosis experimentally to animals.—I am, etc.,

Glasgow.

DOUGLAS K. ADAMS.

### Treatment of Varicose Veins

SIR,—Prof. A. M. Boyd and Mr. D. J. Robertson (Sept. 20, p. 452) discuss some of the causes of the unsatisfactory results in the treatment of varicose veins. They also illustrate their article with some very interesting phlebograms. With regard to the incidence of the condition, the authors state that 95% of patients attending civilian varicose vein clinics are women. This was certainly not the case when I had the vein clinic at St. Bartholomew's Hospital, where I found that approximately one-quarter of my cases were among men, and this figure was borne out by my private cases. I cannot agree with the suggestion that varicose veins seldom cause serious discomfort. The condition invariably develops very gradually and the patient gets used to the increasing heaviness in the limbs. Severe pain is certainly not a common feature, but the discomfort and disability are great and are aggravated by conditions which involve much standing. At the same time, the degree of discomfort is not necessarily related to the actual size or extent of the veins.

Recurrence of varicosities after treatment may mean a failure to obliterate all the incompetent veins; it may mean a gradual recanalization of veins which were obliterated at the time of treatment; or it may mean the gradual development of varicosities in other veins. My own experience has led me to an operation—a combined excision and ligation—with at least two, and possibly three, incisions in the thigh and with two incisions in the calf, with a further large popliteal incision where the external saphenous vein is involved. Subsequently, any small remaining veins are treated by injections. At the same time I do not believe that the mere ligation operation at sites of valvular incompetence of communicating veins will secure obliteration of extensive varicosities, even when combined with simultaneous injections. By suitably planning the direction of incisions it is possible to use the flexure lines of the skin, to get adequate exposure of considerable lengths of the veins, and to avoid incisions in the long axis of the limbs. In one week recently I saw three patients all of whom had had recent ligation and injection operations at the groins, and all of whom showed complete incompetence of the whole saphenous systems right up to the level of the operation scars. Neither the symptoms nor the signs suggested that there had been any appreciable alteration as the result of the treatment.

Operative experience also suggests that by far the most important deep communicating vein is the one situated at the junction of the middle and lower third of the leg as a communication between the internal saphenous vein or one of its branches and the deep veins. Certainly, from the point of view of local symptoms, the failures of injection treatment, and the

local complications such as eczema, ulceration, etc., this is the branch which is so often responsible for a reflux of blood into the superficial veins. The presence of this vein can often be inferred from the physical signs but cannot be proved until operation is carried out.

Prof. Boyd states that between October, 1942, and February, 1943, he saw 12 patients with deep thrombosis following injection treatment in the Army. I am not quite clear from the context whether these patients had had a combination of operation and injections or injections alone. In my own series of approximately 2,000 varicose vein cases I have never seen this complication following operation, operation and subsequent injections, or injections alone. On the other hand, whatever form of treatment is adopted, there are cases which show temporary and transient oedema, particularly on the inner side of the foot and ankle, for some weeks after treatment. This is much more likely to occur where there is much subcutaneous tissue, where operations have been extensive, or thrombosis has been widespread, but I have never known this oedema persist. The proper treatment, of course, is to control the oedema with external support, and, as lymphatic function is re-established, gradually to lessen the external support. In view of what Prof. Boyd says about the reaction of men in the Army to varicose veins, I am wondering if some of the deep thrombosis cases were really post-treatment oedemas and not deep thromboses at all. The presence of an abdominal collateral circulation would be conclusive. The authors suggest that this complication of deep thrombosis may have been due to the passage of injection fluid into the femoral veins, where the circulation may be sluggish. I am sure that some of the sclerosing fluid must get into the deep veins following injections, but there are two comments I would like to make in this connexion. The first is that the more normal the structure of the vein wall, the greater the difficulty in getting thrombosis with sclerosants. And, secondly, that in those patients who have a slight sensitivity to quinine the drug is tasted within approximately 15 to 20 seconds of injection of the peripheral veins of the lower limb with the patient lying down.

London, W.1.

REGINALD T. PAYNE.

SIR,—Prof. A. M. Boyd and Mr. D. J. Robertson's most interesting article on the above subject (Sept. 20, p. 452) calls attention to the unsatisfactory results of the treatment of the all too common varix. I feel that their conclusions tend to advise a standard treatment of varicosities needing surgical care. They state: "Ligation is required at four sites . . ." "High retrograde injection of large quantities of . . . sclerosant is dangerous," etc. I submit that each case of severe varices needs a careful assessment and that varied treatments are called for according to the findings at the time of examination. The Ochsner-Mahomed tourniquet test will tell the operator the site of the incompetent communicating veins. Four standard sites of ligation will then not be found necessary in the majority of cases. For instance, in a large series of cases these surgeons found that it was only necessary to ligate the saphenous below the knee in 2% of patients.

Again, to condemn the use of retrograde injection of a sclerosant into the distal portion of the internal saphenous divided at the fossa ovalis is far too sweeping a statement. If the patient has suffered from an antecedent deep-vein thrombophlebitis care should be observed regarding the use of any sclerosant. Has there been a recent superficial phlebitis? In these cases use no sclerosant if a severe reaction is to be avoided. There are other indications for the modification of the type and amount of sclerosant to be used. The "mid-Hunter blow-out" (aptly named by various American surgeons) is, as proved by Prof. Boyd and Mr. Robertson, responsible for the admission of much sclerosant into the deep system. The careful use of a Stevenson needle (or one of its modifications) can mitigate this risk. Again, hypertonic saline in the hands of Harold Dodd has satisfied him and many others that damage to the normal intima does not occur.

In a short letter I can but endeavour to point out that standardized treatments and dogmatic statements cannot be applied to the vagaries of the varix. It is seldom that two cases present exactly the same problem. The authors of the article under discussion are, however, to be congratulated on calling attention to the fact that the treatment of varices can be

unsatisfactory. There are still many avenues to explore in arriving at the perfect sclerosant and the perfect operation.

—I am, etc.,

London, W.1.

R. ROWDEN FOOTE.

SIR.—Prof. A. M. Boyd and Mr. D. J. Robertson (Sept. 20, p. 452) are to be congratulated on calling attention to the two complications associated with ill-judged surgery of varicose veins. The commonest cause of recurrence after operation is failure to tie the saphena vein flush with the femoral vein and to tie and divide all its terminal tributaries. During the last four years I have seen 123 recurrences of this type. Having collected large series of cases in which both the vertical and oblique incisions were used, I have no hesitation in recommending the latter: it heals so much better, and if rightly placed and of sufficient length it gives all the exposure that can be wished for.

My clinical experience gained in operations on nearly 3,000 cases makes me agree with Boyd and Robertson as to the site and frequency of the incompetent perforating veins. There is no difficulty in discovering the presence of such veins, but it is not always easy unless a very long incision is made to find the exact spot where the vein perforates the deep fascia. In a small percentage of cases the perforating veins are grossly incompetent, and it is essential to divide their flesh with the deep fascia. The most certain, simplest, and safest way of doing this is to remove the saphena vein with a Mayo or Babcock vein enucleator.

Like Boyd I was struck by the frequency of deep thrombophlebitis in Service personnel after the combined ligation-injection treatment of varicosities, and since 1943 I have tied the vein and postponed injections until the patient was walking about normally. This may be slow in producing thrombosis of all the varicosities, but it certainly lessens the risk of deep thrombosis and shortens the convalescence. Finally I should like to support Boyd and Robertson's plea for a careful clinical assessment before operation is advised. The mere presence of varicosities is not sufficient reason for advocating operation or injection.—I am, etc.,

Liverpool.

J. B. OLDHAM.

SIR.—In their article "Treatment of Varicose Veins" Prof. A. M. Boyd and Mr. D. J. Robertson (Sept. 20, p. 452) draw attention to the danger of retrograde injection of sclerosing fluids after ligation and state that recurrence usually occurs from inadequate ligation. With their first statement I am entirely in agreement and have long since abandoned it; further, I would point out the folly of relying on even an extensive thrombosis produced by this method to give a permanent cure. Hanschell showed many years ago that even soundly thrombosed veins, where the thrombosis is caused by sclerosing fluids, frequently recanalize in a remarkably short space of time.

With regard to the adequate ligation, I think their description is over-simple and their claims over-optimistic. My work has led me to believe the arrangement of deep communications is very much more complicated (*Lon. Hosp. Gaz.*, 1945, 48, 221). I believe that it is impossible to be sure of preventing recurrences unless all deep communications are dealt with and that this is not a feasible procedure because of the enormous variations. Many times I have seen veins not previously varicose appear after adequate ligation, and I believe this results from deep communications which were normal when the original operation was performed. I have on one or two occasions ligated such deep communications with most gratifying results.

I think ligation the only method worth using in severe varicose veins despite my previous remarks, but follow-up for years, not months, is needed to be sure the case is cured.—I am, etc.,

Hutton, Essex.

### Antihistamine Drug for Pruritus of Jaundice

SIR.—There is one action of antihistamine drugs to which we are unable to find any reference in the published literature. If it has been recorded previously it is of sufficient importance to warrant a further note. We have found that patients suffering from the pruritus of jaundice, hitherto an intractable therapeutic problem, derive marked relief from the administration of antihistamine drugs. The benefit is so great that it may well make

life intolerable for the jaundiced patient with an inoperable carcinoma.

The drug which we have used entirely is "neoantergan" ("anthisan"), prepared by May and Baker but not yet upon the market. The dosage given was 0.2 g. at four- to six-hourly intervals. Four-hourly dosage appears necessary because the effect of a single dose of antihistamine drugs only lasts for about six hours. It is perhaps for this reason that we have noted in some cases a recurrence of skin irritation in the early hours of the morning, which disappears when the next dose is administered. "Benadryl," which has a similar action and is available, will certainly produce similar benefit.—We are, etc.,

R. B. HUNTER.

D. M. DUNLOP.

Edinburgh.

### New Treatment of Rheumatoid Arthritis

SIR.—At the Bath Rheumatism Congress in May, 1928, I read a paper on the endocrines in arthritis in which I pointed out that women suffering from rheumatoid arthritis who became pregnant experience a marked relief of all their symptoms, but that they relapsed again during the puerperium, and I suggested that the improvement during pregnancy was due to some endocrine change, a flooding with some special secretion or an inhibition of other active gland product. The balance of the endocrines is much more unstable in the female. Stimulation of the secretion of pituitrin by the internal secretion of the ovary is arrested by that of the corpus luteum. It is noteworthy that at about the same time Cumberbatch and Robinson obtained improvement, often lasting in character, by "cooking" the ovaries with diathermy, and they believed that certain forms of arthritis were mainly due to the inactivity of the corpora lutea.

Dr. Imre Barsi raises the whole question again (Aug. 16, p. 252). He assumes that "a hypothetical material circulates in the blood of pregnant women," and, as pregnant women suffering from arthritis materially improve, he has injected the blood of pregnant women into cases of arthritis, with definite and permanent results. Unfortunately, as Dr. M. D. Warren points out (Sept. 13, p. 433), he does not mention if there was any blood grouping having been carried out, and it is quite possible that the improvement was due to protein shock. Case 4 reported by Dr. Barsi was a male aged 66, and he claims that he was definitely cured of his arthritic symptoms. This is difficult to explain, and it certainly looks as if this improvement was more likely due to protein shock.

The whole question should not be allowed to drop, and I would make the following suggestions: (1) That only those cases of atrophic rheumatoid arthritis occurring in young women should be treated by blood transfusion from pregnant women; (2) that blood grouping be carried out; (3) that an equal number of controls be treated with normal blood—i.e., blood from non-pregnant women or males; (4) that records of temperature, sedimentation rate, and blood sugar be fully recorded.—I am, etc.,

Harrogate.

G. L. KERR PRINGLE.

SIR.—I wrote Dr. Imre Barsi requesting information as to typing the blood. He replied: "The typing is very important and must be done with the greatest care. I always use blood of the same type if I can get it; if not, I use type O, but I always make in such cases a cross-typing before transfusion."

So much for the blood grouping, but I should like to know if the haematologists at Oxford could not find out what it is in the blood of the pregnant woman that arrests rheumatoid arthritis.—I am, etc.,

Salisbury.

G. BAYNTON FORGE.

### Penicillin in the Treatment of Diphtheria

SIR.—Recent articles on the use of penicillin in diphtheria prompt me to place on record two cases as follows.

(1) A boy of 8 years was admitted to Shieldhall Hospital on Nov. 4, 1946, on the fourth day of illness. A doctor had not been called earlier, as his symptoms were at first attributed to mumps. He had had immunizing injections in 1940.

(2) A boy of 7 years was admitted on Nov. 5, 1946, on the third day of illness. His doctor had regarded him at first as a case of quinsy.

On admission both patients were profoundly toxic, with profuse nasal discharge, great enlargement of cervical glands, and the fauces

covered with diphtheritic membrane. Throat swabs revealed virulent *C. diphtheriae* (atypical). Each patient was given 40,000 units of antitoxin intravenously and 60,000 units intramuscularly, and within 24 hours of admission a further 40,000 units intravenously. By Nov. 8 neither showed any improvement and a fatal issue seemed almost inevitable. 50,000 units of penicillin was then administered intramuscularly, followed by doses of 20,000 units 3-hourly, which were continued until Nov. 19 and Nov. 17 respectively. By this time each throat was clean, the swelling of glands had subsided, the nose was free of discharge, and the general condition remarkably improved. Recovery was very gradual, being interrupted by palatal and pharyngeal paralysis in both cases, and by ciliary paralysis in one of them. It was 11 weeks from the onset before the patients were considered fit to sit up, and further convalescence was uneventful.

De, Chatterjee, and Ganguli (1947) advocate giving penicillin without serum to mild and moderately severe cases of diphtheria, and report success in a series of 27, but few if any workers of experience in this country will support them in such a hazardous procedure. The need for penicillin in addition to serum in mild and moderate cases is also debatable. Some benefit may be observed where there is superadded septic infection, but for pure diphtheria we have a perfectly efficient remedy in antitoxin. It is for the gravely ill patient coming under observation after several days' illness, when no amount of antitoxin can undo the damage already suffered, that the value or otherwise of penicillin becomes vitally important. One must be clear, however, as to what a really severe case of diphtheria amounts to. Dodds' (1946) group of 13 patients treated with penicillin are nearly all styled "severe pharyngeal," and while they were given considerable intramuscular doses of antitoxin, only one was deemed ill enough to be given an intravenous dose. In four of the "severe" cases, moreover, hospital treatment lasted for only 33 to 35 days, a period quite inadequate for all but the mildest of infections. Long's (1947) three patients were, judging by his reports, all very ill, one indeed being regarded as hopeless, but again none was given an intravenous dose of serum. This writer mentions the striking value of penicillin, of which he advises giving at least a million units per day in severe cases, but states that in this country no case of diphtheria without secondary infection appears to have responded to treatment in a convincing fashion.

In the two cases reported above there was no apparent secondary infection, and a much smaller amount of penicillin was used. The membrane did not clear from the throat much more rapidly than usual, nor was the date determined when the fauces were free of organisms, but in many years' experience of diphtheria I have never seen such a striking recovery as was made by these patients. Hitherto sceptical, I am now convinced that penicillin may be a life-saving agent in this disease. I await the opportunity to find further proof of its value, but grave cases of diphtheria are now rarely observed in hospital.—I am, etc.,

Glasgow.

## The Extent of Neurosis

SIR,—Dr. H. G. St. M. Rees (Sept. 20, p. 468) invites "our older brethren in general practice" to comment on the extent of neurosis to-day compared with what it used to be. I am not now engaged in general practice, but of my 45 years of professional life approximately half that time has been spent in general practice, always with a psychological bias, and the remainder has been spent as a consultant medical psychologist. Moreover, during the war years I took the opportunity of refreshing my experience of general practice by lending a hand to hard-pressed colleagues in their surgeries and visits. I may therefore be considered qualified both by age and experience to express an opinion.

When I look back to the crowded surgeries of my early days in Leeds, and before that to the time when part of my vacation even before qualifying would be spent in "taking surgeries" for my father in London, it seems to me that the greatest difference between then and now is that patients had a simple faith in their doctor and in a bottle of medicine which is lacking to-day. The patient of forty and fifty years ago did not pretend to any knowledge of physiology, still less of pathology, and was content with a simple explanation and his doctor's "say so." To-day he comes full of

morbid fears engendered by advertisements of "stomach powders," vitamins, and hormones, and fed by imperfectly digested scraps of information gained by his wife's attendance at "the welfare," or by comparing notes with an O.P. hospital patient. The patient of bygone years had but two bogies, cancer and consumption, but the modern is familiar with stomach and duodenal ulcers, pernicious anaemias, coronary thrombosis, sinus infections, and has taken up "blood pressure" where the doctors are beginning to leave it off. He has transferred his faith from the practitioner to a clinical armamentarium, from the bottle of medicine to a course of hypodermic injections. This attitude makes nonsense, of course, of the demand for free choice of doctor under the Health Act. For good or ill the old type of family physician, whose personality was his greatest asset, has gone. His place has been taken by the microscope and test-tube.

The changes that have taken place in the art and science and practice of medicine can be gauged by recalling the kind of ailments one dealt with in the old days compared with the present. The bulk of one's patients at the morning surgery would be mothers and their babies. Diets were not standardized, and not every infant flourished on food consisting of "the same as we have ourselves," though some most reprehensibly did so. Rickets and its accompanying catarrhal complications were common, and dirt and sepsis more in evidence. There would be women who came to "engage," and this entailed nothing more than entering the particulars in a book. Antenatal examinations were unknown and would have been regarded as indelicate. My father taught me to deliver under cover of the bedclothes. Among the young unmarried women patients chlorosis and gastric ulcer were common, and extensive varicose ulcers demanding large quantities of Unna's paste were frequent in the elderly. The evening surgeries would bring a larger proportion of men. A simple dyspepsia, not yet described as a "gastric stomach," brought a good many of them and was usually the result of too hearty indulgence in beer. Chronic alcoholic cirrhosis of the liver was frequent, while the secondary and tertiary manifestations of syphilis such as one only meets with nowadays in textbooks were constantly providing problems in diagnosis. Respiratory troubles in the shape of acute and chronic bronchitis were, I feel sure, more common in those days, and like the syphilis were the result of lack of early and effective treatment. Chronic tuberculous abscesses and discharging empyemas took up much time with the necessary dressings. I have a very strong impression too that stone in the kidney and bladder was more common than it is now, and certainly one saw more urethral strictures due to gonorrhoea than one does in these days, again due to ineffective treatment. The early diagnosis of phthisis without the aid of x rays and often without a sputum test kept one clinically on one's toes, and there was always the possibility that an undiagnosed typhoid was sitting on the bench waiting his turn.

Now if I compare all this with my more recent experiences I am tempted to say that the patient of former times went to his doctor because he had something the matter with him, whereas the majority of patients to-day seek aid because they fear that they may have something wrong. There is a change in the character and incidence of neurosis during the last half-century. My early interest in neurotic illness was stimulated by cases of frank hysteria such as one only sees now in the war hospitals. The hysteria was manifested by girls who were frustrated in their love affairs or by married women as a protest against a domineering male. I feel sure that, if there had been the widespread anxiety states which permeate medical practice to-day, I should have noted it.

As for the causes of this change, it would exceed the limits of a letter if I attempted to elucidate them here. I can only point out that frustration produces aggression, and repressed aggression shows itself as anxiety. There are many obvious causes of frustration in these days of austerity, but I believe we must look deeper than that. The whole tendency of social legislation during the last half-century has been to take more and more responsibility off the individual and to put it on the State. The State thus becomes a parent substitute, so that the individual instead of learning self-reliance is kept in a state of pupillage and becomes afraid or unable to take action on his own account. His attitude towards the State is ambivalent just as is the attitude of an adolescent towards the parents. He looks to the State for guidance and protection, but at the same time he resents the control which the State puts on him. There is an increase of masked or repressed aggression and consequently an increase of anxiety.

This reads as if I were a Conservative "die-hard," but actually I am a Socialist and shall welcome the Health Act provided it is implemented in such a way as to encourage the maintenance of mental and physical health in lieu of trying to "cure"

## For disorders of the biliary tract

Dehydrocholic acid, available for oral administration as Dehydrocholin B.D.H. tablets, is recognised as the most active and least toxic of the choleric bile acids.

Dehydrocholin B.D.H. given orally constitutes rational treatment for atonic constipation and 'liverish' conditions attributable to biliary insufficiency.

## OBITUARY

## Obituary

W. E. MILES, F.R.C.S.

Mr. Ernest Miles, who was known all over the world for his abdomino-perineal operation for cancer of the rectum, died in London on Sept. 24. He was also eminent in other fields of surgery and for many years he had been consulting surgeon to the Royal Cancer Hospital.

William Ernest Miles was born in 1869 in Trinidad, the only son of William Miles, J.P., headmaster of the Queen's Royal College in that island, where his son was accordingly educated. Thence he went to the medical school of St. Bartholomew's Hospital, London, where he qualified M.R.C.S., L.R.C.P. in 1891, becoming F.R.C.S. in 1894 at the early age of 25. He was demonstrator of anatomy at St. Bartholomew's from 1896 to 1899, in which latter year he was chosen assistant surgeon to the Royal Cancer Hospital. He reached the senior staff there in 1903, and was also surgeon to the Gordon Hospital for Diseases of the Rectum. Though much mellowed in later years, in his early days he was of a somewhat irascible and uncompromising nature, which may perhaps explain his otherwise unaccountable failure to be appointed to the staff at St. Bartholomew's. The American College of Surgeons made him an honorary fellow in 1930, and four years later he received a similar honour from the Royal College of Surgeons in Ireland. Among the many other distinctions which he achieved were those of Lettsomian Lecturer; member of the National Radium Commission; Honorary Fellow of the French Academy of Surgery; and he was consulting proctologist to the Queen Alexandra Military Hospital, Millbank, and to several other hospitals. He was a keen Territorial officer before the war of 1914, and served in France and Belgium, with the rank of lieutenant-colonel, commanding No. 7 Red Cross Hospital. Later he became D.A.D.M.S. of the 58th Division, and, after commanding No. 56 General Hospital, he was appointed consulting surgeon to the Etaples Area. He contributed the section on diseases of the rectum in *Postgraduate Surgery* and most of his other writings were concerned with general proctology or with cancer of the rectum. Miles was a man of really original mind, with the necessary perseverance to bring his ideas to fruition. As an all round surgeon he was in the front rank, but in his special field of proctology he achieved a reputation that was, and is, world-wide. His thorough training as an anatomist formed the essential background for the development of his rectal operations. It is true that some of his researches into intestinal surgery did not bear the test of time: for instance, his method of "obliterating the left broad ligament," which he devised and for some years practised for the relief of prolapsed sigmoid and the constipation occasioned by it; and also his plan for relieving digestive troubles by cutting a peritoneal ligament which, he thought, impeded the working of the third part of the duodenum. But he was always willing to learn by his mistakes and to abandon a method which time showed to be unserviceable. His routine rectal operations were admirably done and with excellent results, but his reputation has been most securely established by his operative treatment of cancer of the rectum. Basing his work on the most careful and prolonged study of the

post-mortem appearances of metastases, and on observations made in the operating theatre, he devised a formidable technique for the complete removal of malignant growths in one sweeping operation, which, though the death rate was at first higher than that of less extensive procedures, at least showed a much higher proportion of permanent cures than any other method previously available. Devoting himself more and more to perfecting this operation, he quickly reduced the operative mortality to quite a small figure, and he also cut short the time taken to complete the operation. Originally, it needed an hour and a half; by training his assistants very carefully (Mr. Lawrence Abel was foremost among them) and avoiding every unnecessary movement, he got it down to an hour, then to 45 minutes, and eventually by extraordinary surgical dexterity to half an hour and even less. His fame soon spread, and hundreds of visiting surgeons from overseas went to the Cancer Hospital to watch his technique.

In his youth Miles was a keen lawn tennis player, boxer, and a steeplechase rider; he remained a devoted follower of racing, and was said not to have missed seeing the Grand National for fifty years or thereabouts. One of his favourite stories—and he had a big repertory as a raconteur—was of his entertaining a leading Irish surgeon who was attending a conference in London. At the week-end he suggested an afternoon at a race meeting; his visitor said he should like to go, as he had never been to such an event in his life. Following Miles's advice, the visitor backed five winners during the afternoon, and is supposed to have said that he didn't understand why his host found it necessary to labour at surgical work at all.

No account of the career of Ernest Miles would be complete without reference to a lawsuit brought against him in 1930 on the alleged ground of his having left a pair of artery forceps inside the abdomen of a lady upon whom he had operated. The writ was issued more than six years after the alleged tort, so Miles had a perfectly good technical defence, which would have stopped the case at the outset; but he put it very strongly to the Medical Defence Union, by which he was represented, that such a defence might damage his reputation, and it was agreed that it should be waived and the case conducted on the ground that the forceps had not been left by Miles at all but by another surgeon who had operated on the lady in France. This defence was successful, and Miles had the satisfaction of knowing that a jury did not accept the plaintiff's allegation.

After the death of his first wife, he married in 1944 Miss Janet Mary Loxton; there was no issue of either marriage. Ernest Miles was a man of dominating personality and an outstanding figure in the world of surgery. The operation with which his name will always be associated was developed on classical lines. Anatomical and pathological studies, followed by careful observation in the operating theatre, formed the basis of his considerable contribution to rectal surgery. He contributed to the medical press many articles on cancer of the rectum and proctology. His Lettsomian lectures on cancer of the rectum were published as a monograph in 1926. His final summing up of his classical abdomino-perineal operation appeared as a kind of swan song in the *American Journal of Surgery* in 1939.

Dr. Frank H. Lahey, director of the Lahey Clinic, Boston, writes: On being informed of the death of Mr. Ernest Miles this morning it seemed to me that on behalf of the American surgeons who have learned so much from him I should write you expressing for them their deep sorrow. Mr. Miles's name will for ever be linked with the radical operation for abdomino-sacral removal of the rectum. We in America feel that it was he who, for us, put his procedure, which has done so much for so many people, upon a sound basis. Mr. Miles was a gracious host, a stimulating teacher, and I will personally miss him greatly, as will his many friends all over the world.

Mr. Michael Smyth writes: May I add a few remarks to the obituary notice which appeared in *The Times* of Sept. 25. At the zenith of his powers Miles was a world figure in abdominal surgery, particularly in the surgery of the large intestine and rectum. This was not merely because of his great skill as a surgeon, but also because of his outstanding researches in the spread of cancer of these organs. These researches were afterwards embodied in the Lettsomian lectures which he delivered to the Medical Society of London, and from them he evolved the

Janet Devons

operation (abdomino-perineal) which is generally known by his name, and which revolutionized this branch of surgery. Although his name is connected with other operations this particular one brought him fame and honorary fellowships from many countries, the last to arrive coming from Greece only a few weeks ago. In the early twenties the Royal Cancer Hospital, where Miles did most of his work, was the Mecca of surgeons who were interested in diseases of the large intestine. There Miles had collected a team of brilliant young men who made their mark afterwards, and some of whom, alas, have predeceased him—Cecil Joll, Jocelyn Swan, and Cecil Rowntree. To see Miles at work with his assistants was to see British surgery at its best. There was a calm, unhurried atmosphere about the theatre, and the leisurely manner in which he went about his work made the whole performance seem at first somewhat slow. This was deceptive, of course, for there was an economy of movement and an effortless ease which only skill and experience could bring about. There was no delay, no fidget, everything looked simple, and the operation moved on quietly to its close. A glance at the clock showed that it had all taken place in an incredibly short space of time—in fact, as Lord Moynihan remarked, "the clock stood still." And after all there was the chat about the operation, the cup of tea and the cigarette—all very friendly, for Miles was the most approachable of all men, and was kindness itself to visiting surgeons and students. The other hospital to which Miles devoted much of his time was the Gordon. Here some of his greatest work was done. The hospital at first was only a collection of private houses, and poor ones at that, but he and the chairman of the hospital, Capt. Reginald Corfield, worked for years to obtain better housing and to improve conditions for the patients. Eventually their efforts were rewarded when Mr. John Dewar came to their aid, but it is sad to think that Miles had the opportunity of working for only a short time in the magnificent new building they created.

In his youth he was a fine sportsman, excelling particularly in tennis, and he was known to have defeated the reigning tennis champion at tournaments on two occasions. In later years for recreation he indulged in golf, but his chief relaxation was racing. Nothing pleased him more than to entertain his colleagues and friends in his box at Ascot. A story which amused him greatly was that of a distinguished patron of the turf who bade his trainer good-bye, saying that he was about to undergo a big abdominal operation by Ernest Miles. The trainer, who had already undergone an operation by Miles, shook him warmly by the hand and said, "Have no fear, 'mildord,' you are home and dried." Of all the honours which came his way there were a few in which he took especial pleasure. The honorary fellowship of the Royal College of Surgeons in Ireland appealed to him, for on his mother's side he was of Irish descent, and some of his ancestors had served with Wellington in the Peninsula. The other tribute which pleased him greatly was on the occasion of his last birthday when there arrived a present and a letter signed by the members of the staff of St. Mark's Hospital, "wishing him every happiness in his retirement, acknowledging him as a great friend and a trusted leader in their specialty." In the past few years his health had deteriorated, but he had the great good fortune of being tended and nursed by his devoted wife, herself well known in the surgical world. A great surgeon has gone, and all of us regret the passing of a great gentleman.

Dr. Cuthbert Dukes writes: When planning an operation for the eradication of any form of malignant disease the surgeon has first to take stock of all possible paths of lymphatic spread. This was accomplished for the rectum by the pioneer work of Mr. Ernest Miles. He gave a detailed description of the rectal lymphatics, describing them as arranged in three groups—intramural, intermediary, and extramural. He pointed out that the main direction of lymphatic drainage was upwards by efferents accompanying the superior haemorrhoidal vessels to drain into lymphatic glands along the main trunk of the superior haemorrhoidal artery and beyond this to the inferior mesenteric and aortic glands. Mr. Ernest Miles planned the abdomino-perineal operation in 1906 and began to employ it in the following year. He took this step because he was convinced that the tissues of the upward zone of spread lay beyond the reach of any operation carried out solely from the perineum. He pointed out

that when the perineal route is employed it is seldom possible to reach the glands situated above the bifurcation of the superior haemorrhoidal vessels, yet glandular spread may have extended higher than this. The chief merit of the abdomino-perineal operation (and similar combined operations such as the perineo-abdominal and synchronous combined operation) is that they permit the removal of glands at a higher level than is possible by perineal excision. The new operation introduced by Miles forty years ago extended the scope of surgery in the treatment of rectal cancer and brought a prospect of cure to some patients who could not have been cured by earlier surgical procedures.

Mr. A. Lawrence Abel writes: With the passing of Ernest Miles, British surgery loses one of the giants of the first half of this century, and I lose one who has been my surgical father for more than half that time. He performed his first abdomino-perineal operation for cancer of the rectum more than forty years ago, and survived one of his earliest cases by a few months. The Miles operation was soon known throughout the world, and has stood the test of time; to-day, with little or no modification, it is the operation of choice for rectal cancer in the vast majority of surgical centres. Before the first and between the two world wars few of the leading surgeons of the world failed to visit either the Royal Cancer Hospital or the Gordon Hospital to see him work, and Moynihan, Stiles, and the Mayo brothers were among his numerous friends and admirers. So long as cancer of the rectum can be cured only by the surgeon, Miles's name will be honoured for the pioneer work he did; for the firm foundation of pathology and splendid superstructure of finished technique which he has bequeathed to humanity. He has also left us the operation of recto-sigmoidectomy for complete procidentia of the rectum, and a classic work on fistula which well repays reading at frequent intervals. For many years he was the only leading British surgeon to have two major operations named after him. He loved life, men, and horses, a good meal, good company, and a merry story. His annual box at Ascot was a joyous institution for friends and old patients, who so often became his friends. I have seen as many as seven men whose rectums he had removed enjoying his hospitality together, not knowing what the others owed to their host. Our sympathies go out to his wife and we deplore his loss, appreciating all we owe to a staunch friend and valiant surgical pathfinder.

J. C. BRIDGE, C.B.E., F.R.C.S.Ed., D.P.H.

Dr. John Crosthwaite Bridge, consulting medical officer to Imperial Chemical Industries, Limited, and formerly H.M. Senior Medical Inspector of Factories, died at his home in Worthing on Sept. 27.

He was born on June 5, 1877, the second son of the Rev. James Henry Bridge, was educated at Carlisle Grammar School, and received his medical training at the Middlesex Hospital, where he gained an entrance exhibition. He qualified in 1902 and subsequently was admitted F.R.C.S.Ed. in 1910 and M.R.C.P.Ed. in 1920. He also read for the Bar and was called from the Middle Temple in 1913. He soon interested himself in preventive medicine, taking his D.P.H. at Cambridge in 1906. He became a pioneer in the medical inspection of school-children in Dunfermline, then in Devonport, and later as medical officer of health and school medical officer of Breconshire. He entered the Home Office in January, 1914, under the late Sir Thomas Legge, as H.M. Medical Inspector of Factories, retiring in 1942.

Here was work which suited his diverse talents and many interests. Inspired as he could not fail to be by Sir Thomas Legge, whom he succeeded as Senior Medical Inspector of Factories in 1927, his contribution to the progress of industrial medicine was far-reaching in a remarkably wide field. He set out to understand and really know industrial processes. With this understanding, his basic knowledge of medicine and of the law, and a critical judgment, he aided progress far more surely than he believed. As with all outstanding men, his technique was enviable, and his junior colleagues were often amazed at the uncanny way in which he tracked down and identified among the intricate processes of a large factory the precise cause of some complaint. He took a simple pleasure

in doing this when taking out a new colleague, implanting thus a firm desire to emulate this impressive achievement. Afterwards he would generously explain the why and wherefore. Needless to say, the occupiers of factories were equally impressed, particularly as he rarely made a note during a visit.

One of his duties was to advise the Home Office on medical aspects of the law relating to workmen's compensation, and here, too, he left his mark on legislation. He was a member of the Departmental Committee of 1930 on extensions to the schedule of industrial diseases and of another Departmental Committee in 1935 on certain questions arising under the Workmen's Compensation Act. He had a flair for recognizing and assessing the potentialities of industrial processes in relation to health hazards, and in such cases was at pains to identify new occupational diseases and to ensure their consideration with a view to their inclusion in the schedule of diseases subject to compensation. He was chairman of the Departmental Committee on medical arrangements for the diagnosis of silicosis in 1928, a member of the Industrial Health Research Board, of the Industrial Pulmonary Diseases Committee, and of the Committee on Industrial Solvents of the Medical Research Council, and of many other committees, such as the Ministry of Health's committees on the causes and prevention of blindness (1922), on cancer (1928-35), on ethyl petrol (1928), and he served also on the advisory Departmental Committee on anthrax (1935-46), and on the Correspondence Committee on Industrial Hygiene of the International Labour Office from 1927. He was vice-president of the Section of Occupational Diseases at the Annual Meeting of the B.M.A. in Manchester in 1929 and of the Section of Public Health at the Centenary Meeting in 1932. After retirement from the factory department he became chairman of the Association of Industrial Medical Officers.

He had an endearing grace of manner and a sensitive mastery of the spoken word, but could be stern in reproof, and he was intolerant of carelessness. These traits, with his sane and balanced outlook, had an abiding influence on his junior colleagues, to their great advantage. He was much interested in the Whitley Council movement in the Civil Service and had a great influence on the development of the Institution of Professional Civil Servants, of which he was chairman 1922-6 and again in 1930-1. Thereafter his advice and help continued to be freely available to, and was welcomed by, the institution. He was sensitive and inherently shy, but could make a speech full of logic and keen judgment. In the main, however, he chose to reserve his gifts for his internal departmental work and his colleagues rather than seek publicity in writing and speaking. He built something which will endure both in the hearts of the men and women he taught so well and in the law designed to protect the industrial worker.

Dr. Bridge was made a C.B.E. in 1934 and appointed honorary physician to the King in 1937. He married first in 1904 Essie (died 1933), daughter of Gateward Coleridge Davis, and in 1935 Joan Phyllis, daughter of James S. Hann, who survives him with one daughter.

#### C. P. LAPAGE, M.D., F.R.C.P.

Charles Paget Lapage, one of the best-known paediatricians in Manchester, died on Sept. 23 at the age of 68. He was the son of Dr. Charles Clement Lapage, a Cambridge graduate in practice at Nantwich. He was educated at Epsom College and at Owens College, graduating M.B., Ch.B. at Manchester in 1902. Early in his career he was interested in the diseases of children, and he won the John Henry Agnew prize and the Henry Ashby Memorial Scholarship for the study of this subject. As a student he was a notable long-distance runner, and a useful forward in the Rugby team. After graduating he was appointed house-surgeon at the Manchester Royal Infirmary. Later he was resident medical officer to the Royal Manchester Children's Hospital at Pendlebury, and then to the special wards at St. Mary's Hospitals. His teaching experience began when he was medical registrar to the Royal Infirmary and medical tutor at the Hulme hall of residence. By this time he had made up his mind to specialize in paediatrics and he became medical officer to the Gartside Street out-patient branch of the Children's Hospital. This was in 1905, the year in which he was awarded

the M.D. with commendation for a thesis on feeble-minded children.

After the death of Dr. Henry Ashby he was appointed honorary physician to the Children's Hospital and subsequently he was on the honorary staff of St. Mary's Hospitals and in charge of the children's wards. Other honorary appointments he held were in connexion with the Warehousemen and Clerks Schools, the Princess Christian College for Nurses, the Royal Albert Institution for the Feeble-Minded, the Manchester Mothers' Guild, and the Royal Schools for the Deaf at Old Trafford. He was particularly interested in mental incapacity in children, and he wrote a book on feeble-mindedness in children in 1911; a second edition appeared in 1920. He had taken the M.R.C.P. in 1908 and he was elected F.R.C.P. in 1922.

Before the 1914-18 war Dr. Lapage was a captain in the University Territorial Training Corps and he followed Sir Thomas Holland as its commanding officer. As a major in the R.A.M.C. he went abroad with the 57th General Hospital during the war and was mentioned in dispatches for his services. At the University he acted first as a demonstrator in operative surgery, then as lecturer on school hygiene, later as lecturer and finally reader in diseases of children, which last post he held until a chair of child health was created in May of this year.

Dr. Lapage was president for a session of the Manchester Medical Society and of the Section of Diseases of Children of the Royal Society of Medicine. He was a member of the British Paediatric Association, and in 1929 he was president and in 1932 vice-president of the Section of Diseases of Children at the B.M.A. annual meetings. He published many articles in the medical press and contributed the section on functional nervous disorders in childhood to Parsons and Barling's *Textbook on Diseases of Children*. He was also interested in asthma in childhood and in minor digestive disorders. In later years he took a great interest in mountaineering and he was an active member of the University Climbing Club, regularly attending its hill meetings.

Dr. Lapage was always more successful as a clinician than as a teacher, and as a writer than as a lecturer. He was fascinated by any difficult clinical problem, and he wrote well, but he never pretended to enjoy any lectures that he had to give. His outlook was conservative, though he was always ready to make a cautious trial of a new method or a new technique. When it was first proposed to use non-medical speech therapists at a special out-patient clinic attached to the Children's Hospital he was opposed to the idea. Once the scheme was in being, however, and it was one of the first of its kind in this country, he watched it carefully and, convinced of its merits, helped to make it a success. Students as a group thought him aloof and difficult. He would never "talk down" to them and he refused to oversimplify any problem in diagnosis or treatment. Yet to the individual student in the wards or the out-patient department he was most approachable and could be kindness itself.

H. T. A. writes: As a colleague for many years I would like to add my appreciation of Lapage's work, especially at the Royal Manchester Children's Hospital, Pendlebury, where he had been on the staff for nearly forty years. The medical and lay members of this hospital have always worked together in the most harmonious way and Lapage did much to foster this feeling. Apart from his work Lapage was a unique character, and one will always remember his arrival at hospital in an airman's helmet as a precaution against draught in his car and his remarkable upright quick walk down the corridor to his ward, hugging a sheaf of papers. Lapage was one of the original members of the British Paediatric Society, and I do not think he ever missed a meeting. He much enjoyed these meetings and took part in many discussions. He was essentially a family man and his wife accompanied him when he went for holidays in the Lake District, where he loved to climb and walk. His colleagues will all extend their deepest sympathy to his wife and family.

#### W. S. BAINBRIDGE, A.M., Sc.D., M.D.

Dr. W. S. Bainbridge, the well-known American surgeon and a pioneer of cancer research, died in Connecticut on Sept. 22 at the age of 77.

William Seaman Bainbridge, son of the Rev. W. F. Bainbridge, of Providence, Rhode Island, was educated at Mohegan

# 'LUMINAL'

TRADE MARK

BRAND OF PHENOBARBITONE

'Luminal' was the original phenobarbitone. Experience has shown how well-nigh limitless is the range of indications in which its powerful sedative, antispasmodic and hypnotic properties can be employed.

Among its diverse uses we select:- anxiety states, chorea, hysteria, insomnia, migraine, pertussis, pruritus, status epilepticus and vomiting of pregnancy.

'Luminal' and 'Luminal' Sodium are available as Powder, Tablets and Ampoules. Literature on request.

## The Feeding of Premature Infants

The difficulty found by premature infants in the digestion of fat and protein makes it essential for a correct balance to be maintained between these two constituents, and carbohydrate.

The maintenance of this balance is a well-established procedure. It is convenient for the food to be available in a prepared form, avoiding the necessity for adjustments in the home. The formula of **FRILAC** is designed to present Fat, Protein and Carbohydrate in the following ratio:

1 : 1 : 6

In addition, the food contains 320 I.U.'s of Vitamin D per ounce.

## COW & GATE MILK FOODS

Full details of the analysis, and samples for clinical trial are available on request from the Medical and Research Department  
Cow & Gate Ltd., Guildford, Surrey

## Analgesia from a travelling case

The Minnitt Gas-Air Apparatus is ideally suited to the needs of visiting practitioners and midwives alike. Now standard throughout Great Britain, it weighs only 15 lbs. in its travelling case, measures 19" x 12 3/4" x 5" and is specially designed for self-administration by the patient. The flow of gas-air is controlled by the patient's own respiration; complete unconsciousness never occurs as on the verge of insensibility the pressure of the patient's finger relaxes, allowing additional air to enter and dilute the mixture. Muscular action remains unimpaired. A wheeled model for hospitals and nursing homes is also available.

*designed by a  
gynaecologist...*

1934 saw the first adaptation of the principle of the surgical tampon to the absorption of the menstrual flow. Designed by a practising Doctor, Tampax not only won favour with women themselves, but gained the approval of gynaecologists for its alleviation of mental stress and physical discomfort and its guarantee of hygiene and safety—the latter ensured by the patent stitching process which

makes disintegration impossible. Throughout the world today Tampax is recognised as the best form of modern sanitary protection.

If you are not receiving your copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to: Medical Inquiries, Tampax Ltd., 110 Jermyn St., London, S.W.1.

*Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenial aperture would cause difficulty in insertion and withdrawal.*

ake School, Peekskill, New York, and at Columbia University. He was granted the degree of M.D. in 1893, and spent several years in postgraduate study in America and abroad. He was appointed professor of operative gynaecology at the New York Postgraduate Medical School in 1900, and three years later he was also appointed surgeon to the New York Skin and Cancer Hospital. In 1906 he left the Postgraduate School for the chair of surgery at the New York Polyclinic Medical School and Hospital. He acted as consulting surgeon to the Manhattan State Hospital, and was attached to other hospitals in and around New York. During the 1914-18 war he was for some time an operating surgeon in the U.S.S. *George Washington*, and later he served in the Surgeon-General's office. In 1941 he was sent on a special mission by the Navy Department to the Central and South American Republics, and he also represented the United States at the conference at Basle this year of the International Committee of Military Medicine.

His great interest in cancer received recognition in 1906 when he was honorary president of the first International Congress for the Study of Tumours and Cancers. This first congress was held at Heidelberg. He was constantly in touch with research workers in many other countries, and he accumulated a great deal of material on cancer which served as a basis for what was perhaps his most important book, *The Cancer Problem*. This first appeared in 1914 and was later translated into five languages. In this book Dr. Bainbridge tried to give what he himself called "a clear, concise, comprehensive, and available résumé of the world's work with reference to cancer, its history, distribution, aetiology, diagnosis, possibility of prevention, and treatment." His survey ranged from ancient Greece to the cancer research laboratories of the Middlesex Hospital, and from South African herbal remedies to current quackery. It was a remarkable book which ended with a plea for the better education of the profession and the public in matters relating to cancer, and it served a most useful purpose in attracting attention to the subject to which Dr. Bainbridge himself devoted his long life.

Dr. JOHN MURDOCH died suddenly at his home on Aug. 22 at the age of 68. He graduated at Dublin in 1905 and was in general practice first at Market Harborough and later at Thornton Heath and Croydon. During the 1914-18 war he was medical officer at the Ingram Road War Hospital. His son, Dr. John Murdoch, died on active service in East Africa in 1943.

Dr. GEORGE HERBERT STEELE died in hospital on Sept. 1 at the age of 80. Dr. Steele was a student of Guy's Hospital and qualified in 1898. He held house appointments at hospitals in Birkenhead, Windsor, and Northampton before starting in general practice near Hereford. After the 1914-18 war he moved to Kempsey, near Worcester, and there he remained in practice until his retirement in July, 1946.

## The Services

Surgeon Rear-Admiral O. D. Brownfield, O.B.E., R.N., has been appointed an Honorary Physician to the King in succession to Surgeon Rear-Admiral H. M. Whelan, R.N., deceased.

Surgeon Captain C. C. Elliott, D.S.C., V.R.D., R.N.V.R., has been appointed an Honorary Physician to the King in succession to Surgeon Captain H. O. Martin, V.R.D., R.N.V.R., who has been placed on the Retired List.

Lieutenant-Colonel R. Coyte, O.B.E., Majors (Honorary Lieutenant-Colonels) C. A. Ferguson and W. Slater Brown, and Captain (Honorary Major) W. D. Richardson, M.B.E., R.A.M.C., have been awarded the Efficiency Decoration of the Territorial Army.

The Prince Regent of Belgium has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

Officer of the Order of Leopold with Palm, Croix de Guerre 1940 with Palm.—Colonel J. H. C. Walker, late R.A.M.C., and Colonel (temporary) D. Bluett, O.B.E., R.A.M.C.

Chevalier of the Order of Leopold II with Palm, Croix de Guerre 1940 with Palm.—Colonel (acting) E. H. P. Lassen, D.S.O., Lieutenant-Colonel (temporary) J. Shields, Majors (temporary) R. F. Lawrence and G. A. Stephen, Captains R. F. Clark, G. L. K. Crampton, R. de Senneville, G. Gregg, and L. G. J. Pitt-Payne, and Lieutenant H. Skinner, R.A.M.C.

## Medico-Legal

### OVERDOSE OF AMETHOCAINE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A patient at Crumpsall Hospital died from an overdose of amethocaine hydrochloride. At the inquest before Mr. G. Jessel Rycroft, the Manchester City coroner, the surgeon said that he had read over the shoulder of the theatre sister the label of a large ampoule and had not noticed that it described a 1% solution. The theatre sister said that she had thought that the ampoule contained only one dose of a 0.1% solution. Otherwise, "multi-dose bottles" were normally used. The coroner remarked that it might well have been the duty of the surgeon to be certain of the writing on the label of the ampoule. If a small ampoule had been used, as was usual, the need for dilution of its contents would have been obvious, but the hospital dispensary had been obliged to use a large ampoule because there were no small ampoules or multi-dose bottles available. He pointed to the need for clearer labelling.

<sup>1</sup> Manchester Guardian, Aug. 26.

## Universities and Colleges

### UNIVERSITY OF LONDON

Peter Byers Ascroft, M.B.E., M.S., F.R.C.S., has been appointed to the University Chair of Surgery tenable at Middlesex Hospital Medical School, from July 1 last.

Prof. William James Hamilton, M.Sc., M.D., D.Sc., has been appointed to the University Chair of Anatomy tenable at Charing Cross Hospital Medical School, from Oct. 1.

Graham William Hayward, M.D., F.R.C.P., has been appointed to the University Readership in Medicine tenable at St. Bartholomew's Hospital Medical College from Oct. 1.

### UNIVERSITY OF LEEDS

The inaugural lecture of the Faculty of Medicine of the University will be given by Prof. Geoffrey Jefferson, C.B.E., M.S., F.R.C.S., F.R.S., professor of neurosurgery in the University of Manchester, in the Riley-Smith Hall of the University Union on Thursday, Oct. 16, at 3.30 p.m. His subject is "Scepsis Scientifica." Members of the medical profession are invited to be present.

### UNIVERSITY OF ABERDEEN

At a Graduation Ceremony on Sept. 17 the following medical degrees were conferred:

M.D.—A. A. Harper.  
[CH.M.—P. H. Theron.  
M.B., Ch.B.—J. B. Johnstone, A. J. Watson, Hilda Aitken, W. A. Anderson, Dorothy E. Barron, I. C. Brannen, A. W. Bruce, Nan H. Bruce, W. A. Cramond, I. M. Cran, R. S. Forrester, D. J. Gill, Margaret S. Hamilton, Elizabeth C. Hendrie, J. Hendry, A. Hunter, A. F. Johnstone, Moyra S. M. Kemp, Una Lawrie, K. M. Leighton, Kathleen J. Logan, Kathleen McCombie, A. D. Macdonald, D. McIntosh, A. M. Mackay, J. F. Mackie, Bertine J. C. Mackintosh, P. Marioni, Lorna C. Milne, D. S. Munro, Mary L. Price, W. I. Reid, G. L. Ritchie, A. McC. Robertson, G. Ross, J. Savy, Mary A. Shirreffs, D. W. C. Smith, D. T. Thomson, W. G. Thomson, A. C. Turnbull, J. H. Watson, K. C. Watson, J. N. Wattie, Grace A. M. Webster, Catherine J. J. Wilson, Margaret C. Wood.  
D.P.H.—A. P. Buchan, R. W. Farquhar, F. S. A. Forbes, Mary M. Martin, C. C. Wright.

<sup>1</sup> Awarded Highest Honours for Thesis. <sup>2</sup> Awarded Honours for Thesis. <sup>3</sup> With second-class Honours.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

In the list of members of the Board of the Faculty in Dental Surgery of the College, printed in the *Journal* of Aug. 30 (p. 353), Mr. A. C. McLeod should have been described as "Surgeon-Dentist to the King" and not "Honorary Dental Surgeon to the King."

### ROYAL COLLEGE OF SURGEONS IN IRELAND

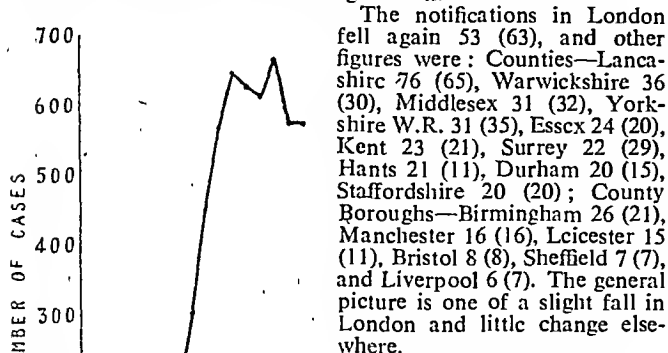

A postgraduate course in surgery will be held at the College and various Dublin hospitals from Monday, Oct. 6, to Saturday, Nov. 29. Attendance will be strictly limited to 30 persons and the fee for the course is £21, but registration may be made for either half of the course at a fee of £10 10s. Applications should be addressed to Prof. N. Rae, D.Sc., Registrar of the College, Dublin.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis and Polio-encephalitis

The number of notifications of poliomyelitis in England and Wales in the week ended Sept. 20 was 571, as against 572 in the preceding week, and of polio-encephalitis 23 (42). The graph shows the notifications each week from May 31 to Sept. 20.

A most interesting feature of the returns is the sudden fall in notifications of polio-encephalitis, which are lower than they have been since the week ended July 19. The figures are small, and it is of course impossible to draw any firm conclusions from the notifications for a single week.

The notifications in London fell again 53 (63), and other figures were: Counties—Lancashire 76 (65), Warwickshire 36 (30), Middlesex 31 (32), Yorkshire W.R. 31 (35), Essex 24 (20), Kent 23 (21), Surrey 22 (29), Hants 21 (11), Durham 20 (15), Staffordshire 20 (20); County Boroughs—Birmingham 26 (21), Manchester 16 (16), Leicester 15 (11), Bristol 8 (8), Sheffield 7 (7), and Liverpool 6 (7). The general picture is one of a slight fall in London and little change elsewhere.

In the week ending Sept. 13 the 572 notifications of poliomyelitis were the lowest for five weeks. The disease was still widespread, and only three English counties—Norfolk, Rutland, and Westmorland—did not report a single case. In Wales the notifications were confined to the southern counties; six counties in the north—Anglesey,

Caernarvon, Flint, Merioneth, Montgomery, and Radnor—had no notifications. The largest returns among the county boroughs were: Birmingham 21, Manchester 16, Leicester 11, Bristol 8, Liverpool 7, Salford 7, Bradford 7, Sheffield 7, Derby 6, and Leeds 5. In London the largest returns were from the boroughs of Lewisham 7, Wandsworth 7, Lambeth 6, and Shoreditch 6. In the remainder of the country the only large centres of infection were Middlesex, Willesden M.B. 6, and Kent, Bromley M.B. 5.

## Neonatal Gastro-enteritis at Rochdale

The Birch Hill Maternity Home at Rochdale is contained in a separate block of the hospital and is divided into two floors with separate staff and independent equipment. The top floor only was affected. This floor consists of a private wing with six single wards (1-6); one two-bedded (7-8); and wards with four beds (9-12), two beds (13-14), three beds (15-17); and eight beds (18-25), together with a common baby nursery and bathroom.

The outbreak began on Aug. 26-7, when a baby 9 days old began vomiting. This was at first regarded as probably due to loric stenosis. The appearance of green stools on Aug. 27 the occurrence of another case on the same day aroused suspicion. The sequence of events is shown in the table.

riefly, following these first two cases, 13 other cases occurred, and there were in all 7 deaths, although one was probably due in the main to prematurity. The last deaths occurred on Sept. 1. Of these cases, 8 (2 deaths) were breast-fed, 6 (3 deaths) were breast- and artificially fed, and one baby which died was fed by expressed breast milk (Case 6).

Of 14 other children not affected 10 were breast-fed, 2 breast- and artificially fed, and 2 artificially fed. In all but the first

case green stools were the first abnormality to be noted, preceded by a few hours of variable malaise and lethargy. Later the stools became loose, and then yellow and watery in the worst cases. Dehydration was rapid and jaundice was present at some stage in most cases. Blood was present in the stools in only one case and mucus in one other case. Both oral and intramuscular penicillin were used, but fatalities occurred so rapidly that assessment of treatment was almost impossible.

Investigation was undertaken by the Rochdale Public Health Laboratory and the Manchester University Laboratory. The only significant organism found was coagulase-positive *Staph aureus* in the post-mortem material, in the stools of certain survivors, and in the nose and throat of mothers with one exception, and of 8 members of the nursing staff on this floor. Confirmation awaits phage-testing.

The floor was cleared of patients and staff on Sept. 12. It has been cleaned, aired, and redecorated, and was reopened on Sept. 30.

## Discussion of Table

In England and Wales infectious diseases were less prevalent during the week; the only rises were in the notification of scarlet fever 134 and diphtheria 17, while decreases were recorded for measles 409, whooping-cough 164, acute poliomyelitis 90, paratyphoid fever 15, and cerebrospinal fever 11.

A small rise in the incidence of scarlet fever occurred in most areas; the largest increase was 31 in Yorkshire West Riding. An outbreak of diphtheria was reported from Warwickshire, Birmingham C.B., where the notifications rose from 2 to 17. In all other areas there was practically no change in the trend of diphtheria.

Relatively substantial falls in the notifications of measles were recorded in most areas of the country. The local trends of whooping-cough fluctuated; the decreased incidence was mainly contributed by Lancashire, London, and the South-eastern counties, while the largest increases were those of Essex 38, Warwickshire 30, and Yorkshire West Riding 25.

The outbreak of paratyphoid in Bedfordshire subsided; only 3 cases were notified during the week. The chief centre of dysentery was Lancashire 19 (Liverpool C.B. 10 and Prestwich M.B. 5).

In Scotland there were rises in the notifications of acute primary pneumonia 46 and scarlet fever 44, while falls were recorded for acute poliomyelitis 19, and cerebrospinal fever 8. The rise in the incidence of pneumonia occurred throughout the western area. The only notable exception to the small general decline in poliomyelitis was a rise of 10 in Ayr county.

In Eire the chief feature of the returns was an increase of 24 in the notifications of diarrhoea and enteritis. In Dublin C.B. 109 of the 120 cases were notified; the other 11 cases involved 5 registration areas.

## Recent Birth-rate Trends in Europe

In the *Monthly Supplement* for August to the Weekly Epidemiological Record of the United Nations World Health Organization the trend of the birth rate, between 1911 and 1946, for European countries has been reviewed. Broadly, the course of the birth rate for all European countries has been the same—a very steep fall during the war of 1914-18, followed by a large increase in 1920 with a subsequent steady decline until 1941, when the rate began to rise again. The only notable exception to the general trend was Germany, where the rate rose during 1934-9 and then fell in 1942. There have been minor changes in the relative positions of some countries, but the changes have been small and, generally, the countries with the lowest rates in the pre-war period had the lowest rates in 1946.

## Week Ending September 20

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 805, whooping-cough 1,378, diphtheria 189, measles 1,066, acute pneumonia 252, cerebrospinal fever 35, acute poliomyelitis 571, acute polio-encephalitis 23, dysentery 100, paratyphoid 23, and typhoid 16.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 13.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Medical News

## Sir Andrew Davidson's Visit to America

Sir Andrew Davidson, Chief Medical Officer, Department of Health for Scotland, has left for America, where, on the invitation of the president and council of the American Public Health Association, he is to address the association's annual conference at Atlantic City on Oct. 7 and 8. Sir Andrew is also to visit Canada, where, on Oct. 14, he will address a conference on rheumatism and arthritis convened by the Department of Health and Welfare, Ottawa. He will return at the beginning of November.

## To Lecture in Hungary

Prof. W. C. W. Nixon, Professor and Director at the Obstetric Clinic of University College Hospital, London, left Britain on Oct. 1 to lecture in Hungary, under the auspices of the British Council, on analgesia and anaesthesia in obstetrics, the development of maternity and child welfare services in Great Britain, and antenatal and post-natal care. He will also demonstrate surgical operations at Budapest.

## Hospitals for Streptomycin Treatment

The following hospitals should be added to those listed (Sept. 6, p. 399) at which cases of tuberculous meningitis and miliary tuberculosis may be received for treatment with streptomycin:

London.—Hospital for Sick Children, Great Ormond Street, W.C.1.

Birmingham.—The Queen Elizabeth Hospital (which takes adults; children are admitted to the Children's Hospital).

The total number of beds for which streptomycin treatment is available for cases of tuberculous meningitis and miliary tuberculosis in the United Kingdom is still 150, the number for which supplies of the drug are at present available.

## Penicillin Research

Miss W. G. Keepe, B.Sc., who has been engaged on penicillin research for the past year, has been appointed to the Wellcome Pharmaceutical Research Fellowship for the academic year beginning in October. She will carry out her research at Manchester University.

## Medical Historian Honoured

The King has granted to Dr. E. Ashworth Underwood, Director of the Wellcome Historical Medical Museum and Honorary Lecturer in the University of London (University College), permission to wear the Cross of the Chevalier of the Legion of Honour, which has been conferred on him by the President of the French Republic.

## London Hospital Old Students' Dinner

The London Hospital Old Students' Dinner and Course will not be held this year on account of catering restrictions.

## Wills

Dr. John Robinson Harper, C.B.E., Barnstaple, Devon, who died on April 30, left £20,207; Dr. Samuel Barratt Browning, of Birmingham, £24,403; and Dr. Prideaux George Selby, O.B.E., of Lyasted, Kent, £15,178.

## COMING EVENTS

## Whipps Cross Hospital Medical Society

The next meeting of the Whipps Cross Hospital Medical Society will be held at the hospital to-day (Friday, Oct. 3), at 8.30 p.m., when Mr. Alan Todd will deliver a lecture on "Cases Illustrating Certain Orthopaedic General Principles."

## National Hospital

An introductory lecture for the autumn term at the National Hospital, Queen Square, Medical School will be given by Dr. Gordon Holmes, F.R.S., on "Co-ordination of Movement and Its Disorders" on Monday, Oct. 6, at 3.30 p.m. in the lecture theatre. The lecture is open free to postgraduate students.

## London Jewish Hospital Medical Society

Dr. Hugh Gainsborough, F.R.C.P., will deliver the presidential address before the London Jewish Hospital Medical Society at Woburn House, Woburn Square, London, W.C., on Thursday, Oct. 9, at 3 p.m.

## Charing Cross Hospital Medical School

In view of the present crisis and the restrictions on rationing, it has been decided not to hold the annual dinner of Charing Cross Hospital Medical School this year. The prize-giving will take place in the council room of the Hospital on Tuesday, Oct. 14, at 3.45 p.m., when the Earl of Donoughmore will present the prizes.

## Conference on Food and Drink Infections

The Central Council for Health Education (Tavistock House (North), Tavistock Square, London, W.C.) has arranged a conference of representatives of local authorities in England, Wales, and Northern Ireland and of the food-handling industry on food and drink infections to be held at Friends' House, Euston Road, London, N.W., on Thursday, Oct. 9, at 10 a.m. The chairman, Lord Woolton, will deliver the opening address and a message will be read from the Rt. Hon. Aneurin Bevan, Minister of Health; Sir William Savage will speak on "The Problem"; Prof. G. S. Wilson on "The Nature of the Food and Drink Infections"; Mr. L. H. Lampitt, D.Sc., on "Present-day Practice and Problems"; Dr. Robert Cruickshank on "Food and Drink Hygiene in the U.S.A."; and Dr. Robert Sutherland on "Health Education and the Food and Drink Infections." A general discussion will follow. There will be an exhibition relating to food and drink infections on view in Friends' House on Oct. 9, from 9 a.m. to 6 p.m., and on Oct. 10 visits to a bacteriological laboratory and to food-handling establishments in London will be arranged. Dr. Robert Sutherland, medical adviser and secretary of the Central Council for Health Education, and Dr. Robert Cruickshank, director of the Central Public Health Laboratory, will be present at the Press conference on Monday, Oct. 6, at 11.30 a.m. at B.M.A. House, Tavistock Square, London, W.C., to answer questions of a technical nature.

## Royal Institute of Public Health and Hygiene

The Royal Institute of Public Health and Hygiene has arranged a series of lectures to be delivered in the Lecture Hall of the Institute, 28, Portland Place, W., on the following Wednesdays at 3.30 p.m.: Oct. 15, Prof. H. J. Seddon, D.M., F.R.C.S., Infantile Paralysis (illustrated); Oct. 22, Mr. J. Lyle Cameron, M.D., F.R.C.S., The Care of the Mother (illustrated); Oct. 29, Dr. W. G. S. Pepper, The Doctor in Industry (illustrated); Nov. 5, Mr. Arthur Ling, The Health Factor in Town Planning (illustrated); Nov. 12, Prof. W. C. W. Nixon, M.D., F.R.C.S., Diet in Pregnancy (illustrated); Nov. 19, Mr. L. Z. Cosin, F.R.C.S., Modern Methods in the Care of the Aged (illustrated); Nov. 26, Dr. Mary D. Sheridan, Hygiene in the Nursery and Playroom (illustrated). Admission to the lectures is free and applications for reservation of seats should be made to the secretary of the Institute.

## SOCIETIES AND LECTURES

## ROYAL SOCIETY OF MEDICINE

**Section of Epidemiology and St.** Monday, Oct. 6, 4.30 p.m. Papers by Mr. K. I. Nielsen, Heinen, 1945; Dr. L. M. Laurent: Acute Undetermined Virus Aetiology. A discussion will be opened by Douglas McAlpine with "Some Observations on the 1947 Outbreak of Acute Poliomyelitis."

**Section of Orthopaedics.**—Tuesday, Oct. 7, 8.30 p.m. Presidential Address by Mr. George Perkins: Flat-foot or Instability of the Longitudinal Arch. A discussion will follow.

**Section of Physical Medicine.**—Wednesday, Oct. 8, 4.30 p.m. Presidential Address by Dr. W. S. Tegner: Treatment of Rheumatoid Arthritis.

**Section of Ophthalmology.**—Thursday, Oct. 9, 5 p.m. (Cases at 4.30 p.m.) Paper by Dr. H. Arruga (Barcelona): Considerations on the Treatment of Detachment of the Retina.

**Clinical Section.**—Friday, Oct. 10, 5 p.m. (Cases at 4 p.m.)

**INSTITUTE OF PHILOSOPHY.**—At University Hall, 14, Gordon Square, London, W.C., Friday, Oct. 10, 5.15 p.m. Prof. H. B. Acton: Morals and Politics in Contemporary Society.

**CHADWICK TRUST.**—At 26, Portland Place, W., Tuesday, Oct. 7, 2.30 p.m. Brig. A. E. Richmond: Positive Health—Its Attainment in the Soldier, and the Army's Contribution to it in the Civilian.

**INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY,** 330, Gray's Inn Road, W.C.—Friday, Oct. 10, 4.30 p.m. Annual Address by Sir Francis Fraser: The Training of Specialists: The Place of Postgraduate Institutes.

**LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.**—At Leeds General Infirmary, Friday, Oct. 10, 8.30 p.m. Dr. John T. Ingram: Sir Jonathan Hutchinson, Dermatologist.

**LONDON: UNIVERSITY COLLEGE,** Gower Street, W.C.—Tuesday, Oct. 7, 5.15 p.m. Prof. J. Z. Young, F.R.S.: Structure of Peripheral Nerve and of Nerve Endings. Wednesday, Oct. 8, 5 p.m. Dr. M. H. Pirenne: Physiological Mechanisms of Vision.

**ROYAL DENTAL HOSPITAL OF LONDON AND LONDON SCHOOL OF DENTAL SURGERY (UNIVERSITY OF LONDON),** 32, Leicester Square, W.C.—Saturday, Oct. 11, 3 p.m. Prize Distribution by Sir Ernest Graham-Little and Conversazione.

**SOCIALIST MEDICAL ASSOCIATION.**—At Denison House, 296, Vauxhall Bridge Road, S.W., Thursday, Oct. 9, 7.30 p.m. Dr. Marc Daniels: Health Services in Post-war Poland.

## POSTGRADUATE DIARY

**GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.**—Wednesday, Oct. 8, 8 p.m. Prof. A. Loewenstein: Pathology and Clinical Aspects of Ocular Glassmembranes.

**LONDON SCHOOL OF DERMATOLOGY,** 5, Lisle Street, Leicester Square, W.C.—Tuesday, Oct. 7, 5 p.m. Dr. R. T. Brain: Congenital Abnormalities. Thursday, Oct. 9, 5 p.m. Dr. C. W. McKenny: X-ray Technique.

The Fellowship of Medicine announces the following courses: (1) Obstetrics and Gynaecology, at Nuffield Department of Obstetrics and Gynaecology, Radcliffe Infirmary, Oxford, all day from Oct. 21 to 31. (2) Week-end course in Rheumatic Diseases, at Rheumatic Unit, St. Stephen's Hospital, Fulham Road, S.W., all day Saturday and Sunday, Oct. 25 and 26. (3) Week-end course in General Medicine and Surgery, at National Temperance Hospital, Hampstead Road, N.W., all day Saturday and Sunday, Oct. 18 and 19. Full particulars of these courses can be obtained from the Fellowship of Medicine, 1, Wimpole Street, London, W.

The series of neurological and psychiatric demonstrations by Dr. A. Feiling and Dr. D. Curran at St. George's Hospital Medical School resumed on Oct. 2, when Dr. Feiling gave a neurological lecture-demonstration. The series will be continued on Thursdays at 4.30 p.m. and is open to practitioners and senior students without fee.

## APPOINTMENTS

Dr. Alan C. Lendrum, Lecturer in Pathology at Glasgow University, has been appointed Professor of Pathology at St. Andrews University and Senior Pathologist and Clinical Pathologist at Dundee Royal Infirmary.

Prof. T. B. Davie, Dean of the Faculty of Medicine and Professor of Applied Pathology at Liverpool University has been appointed Vice-Chancellor of the University of Capetown.

Prof. Davie, who is 59 years old, took his M.B., Ch.B. (with first-class honours) at Liverpool in 1928, proceeding M.D. in 1931. In 1940 he was elected F.R.C.P.

Hugh Llewelyn Glyn Hughes, C.B.E., D.S.O., M.C., M.R.C.S., L.R.C.P., has been appointed Senior Administrative Medical Officer of the South-East Metropolitan Regional Hospital Board.

Hugh Montagu Cameron Macaulay, M.D., D.P.H., has been appointed Senior Administrative Medical Officer to the North-West Metropolitan Regional Hospital Board.

Dr. Macaulay is County Medical Officer of Health and School Medical Officer for Surrey and only recently completed his term of office as Honorary Physician to the King.

Percival V. Pritchard, M.D., F.R.C.P.Ed., F.R.F.P.S., D.P.H. Deputy Medical Officer of Health, St. Pancras, has been appointed County Medical Officer, Antrim, Northern Ireland, and will take up his new post this month.

HUGHES, E. S. R., M.S., F.R.C.S., Temporary Honorary Surgeon, Connacht Hospital, Walthamstow, London, E.

MAHONY, G. H., M.D., M.Ch., F.R.C.S.Ed., F.R.C.O.G., Lieutenant-Colonel I.M.S. (ret.), Professor in Obstetrics and Gynaecology, Royal College of Medicine, Baghdad, Iraq.

WHITELAW, A. D., M.D., D.P.H., Medical Officer of Health, East Pembrokeshire Combined Districts.

WREXHAM EMERGENCY (COUNTY GENERAL) AND WREXHAM AND EAST DENBIGHSHIRE WAR MEMORIAL HOSPITALS.—Physician: J. R. Forbes, M.D. M.R.C.P. Anaesthetist: R. J. Whiting, M.B., B.S., D.A. Assistant Physician: P. R. C. Evans, M.D., M.R.C.P. Assistant Ear, Nose, and Throat Surgeon: R. Barracough, M.B., Ch.B., D.L.O.

WOOD, PHILIP M., M.B., Ch.B., D.O.M.S., F.R.C.P., Visiting Ophthalmic Surgeon, Royal Halifax Infirmary.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

## BIRTHS

GOLDING.—On Sept. 22, 1947, at Haslingden, to Frances Rosalie (née Heneghan) M.B., B.S. (Dun.), the wife of Dr. C. D. C. Golding, a son.

HALLIDAY.—On Sept. 4, 1947, at Wakefield, to Beryl, wife of Dr. R. Halliday, a daughter—Patricia Alexandra.

MACWILLIAM.—On Sept. 22, 1947, at Bank Hall Maternity Hospital, Burnley, to Cicely (née Gray), wife of Dr. J. C. MacWilliam, a daughter.

## MARRIAGE

MICHELL—PEARCE.—On Aug. 30, 1947, in London, Guy Michell, M.B., M.R.C.P., to Anne Pearce, S.R.N.

## DEATHS

LAPAGE.—On Sept. 23, 1947, at Didsbury, Manchester, Charles Paget Lapage, M.D., F.R.C.P.

STEPHEN.—On Aug. 30, 1947, at Cross Brook, Todmorden, Thomas Cook, L.M.S.S.A., L.D.S., R.C.S. (Eng.), aged 64 years, dearly loved husband of Alice Stephen.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Spasm in Poliomyelitis

**Q.**—One hears a good deal about spasm of muscles in cases of anterior poliomyelitis. From the description given it seems that this occurs apart from the rigidity of the spinal muscles resulting from meningeal irritation, and is not due to an upper motor neurone lesion. How can this spasm be recognized and what is the physiological mechanism involved?

**A.**—The spasm that is alleged to occur in the muscles of the limbs in the acute phase of poliomyelitis is a great mystery. Miss Kenny and her disciples, particularly those in America, regard it as of frequent occurrence and, indeed, as an essential feature of the disease. On the other hand, many competent observers in America and this country have sought for it most diligently with almost uniformly negative results. In Chicago a team of clinicians directed by Dr. L. J. Pollock kept continuous watch over a number of patients in the acute phase of the disease and failed completely to detect spasm in the limb muscles at any hour of the day or night. In his recent article (Aug. 30, p. 319) Seddon mentions that he found no unequivocal evidence of spasm in the muscles of the limbs in some 1,500 early cases of the disease. On the other hand, the writer has seen electromyographic tracings made by competent observers from muscles said to be in a state of spasm, and they showed irregular electrical activity even when the muscle was apparently at rest. It appeared that the muscle was twitching in a fascicular fashion, and it would be proper to describe such a state as one of true spasm. Thus, in spite of much negative evidence, one cannot deny the possibility of its occurrence though there is no doubt that in this country, at any rate, the condition is rare.

No clear explanation of the pathology of spasm has yet been given, though it is agreed that it is almost certainly a lower motor neurone phenomenon, like the spasm that so commonly occurs in the spinal muscles in poliomyelitis and which is undoubtedly due to meningeal irritation. There are two possibilities: the origin of the spasm may be motor or sensory. It is conceivable that at the periphery of a zone of severe damage to the anterior horn cells of the cord the virus might be present in low concentration and exert an irritative strychnine-like action on the cells; these cells would then be in a state of irritation, firing off impulses which would throw the motor units they supplied into irregular contraction. The likelihood of spasm being due to a disturbance which is primarily on the sensory side, however, is supported by the recent demonstration of quite extensive changes in the posterior root ganglia in fatal cases of poliomyelitis; there is often a most intense cellular infiltration. These changes might be manifest clinically as pain in a limb, which is exceedingly common, and by reflex stimulation of anterior horn cells in the adjoining cord.

### Pituitary Extract and Obesity

**Q.**—Has anterior pituitary extract, when given by mouth, any effect on obesity associated with pituitary dysfunction, and, if so, what? A woman aged 41, with two children, has been grossly over weight since a girl, and has in the past been treated with tablets containing thyroid and anterior pituitary gr. 1½ (11 mg.). In her twenties a pituitary lesion was diagnosed radiologically. She had a breast removed for carcinoma in 1940 and subsequently had radium treatment. Lately she has had attacks of sleepiness that suggest a pituitary origin.

**A.**—Anterior pituitary gland or powdered extract by mouth in hypophysectomized tadpoles increases growth but does not lead to repair of atrophied adrenals, thyroid, or gonads. It has, however, no effect whatsoever in mammals. This is the experimental evidence, and clinically no objective data have been produced to indicate that man behaves differently from other mammals. Nevertheless, from time to time claims of benefit are made, and there is no doubt that pituitary by this route

will continue to be prescribed empirically, although it should be realized that it is contrary to scientific evidence. Sleepiness occurs with hypothalamic lesions, and also with so-called pituitary adiposity when there is no gross evidence either of an organic pituitary lesion or of a hypothalamic one.

### Syphilis and Marriage

**Q.**—A Southern European had a penile sore three months ago, with a positive blood test; he had a course of nine intramuscular and nine intravenous injections in his home country. He wants to get married shortly. What further treatment should be given, and how soon can he be allowed to marry? It is doubtful whether I can get Wassermann tests carried out here (East Africa).

**A.**—If penicillin is available 2,400,000 units should be given over a period of 7½ days in equally spaced injections; in addition a course of ten injections each of 0.6 g. of neoarsphenamine or similar drug and ten injections each of 0.2 to 0.25 g. of bismuth metal should be given concurrently over a period of nine to ten weeks, with the usual precautions. If penicillin is unobtainable at least three courses of arsenic and bismuth, as outlined above, should be given; intervals between courses may be four to five weeks. If there are no facilities to have Wassermann tests carried out it should be possible to get flocculation—for example, Kahn standard—tests done; for this purpose serum sent through the post should be satisfactory provided it is put up under strictly aseptic conditions. Marriage should be forbidden until five years have elapsed since the date of infection, but this period may be somewhat shortened if the patient reacts well to treatment and his blood reactions reverse rapidly.

### "Wax Rash"

**Q.**—Workers handling chlorinated naphthalene in the manufacture of certain types of wax suffer from chlor-acne. What are the prophylaxis and treatment?

**A.**—The rash is caused by the fumes from a heated wax containing chlorinated naphthalenes (or chlorinated diphenyls). Prevention of the rash lies, therefore, in avoiding contact between the skin and such fume. This can be effected by localized mechanical exhaust ventilation applied to the vessel in which the wax is treated. High-necked overalls should be worn by operatives, and careful washing of the skin is important. No food should be taken at the site of work. As well as causing a skin rash, the chlorinated naphthalene waxes and chlor-diphenyls may be toxic to the liver. Periodical medical supervision of workers in contact with these substances, whether heated or not, is desirable. The first step in the treatment of "wax rash" is, of course, removal from contact, and here the contamination of clothing should be remembered. The subsequent treatment is that appropriate to the acneiform eruption on the exposed skin, and a watch should be kept for any symptoms of hepatic origin.

### Gold Therapy of Rheumatism

**Q.**—In what proportion of cases of rheumatism is gold therapy effective? What are the dangers and contraindications?

**A.**—It is impossible to give an estimate of the effect of gold therapy in rheumatism. It is probably effective only in rheumatoid arthritis, though often given by those who are not acquainted with its use to patients suffering from other forms, such as osteo-arthritis and fibrositis, without any beneficial effect and with possibly harmful results. Its use should generally be limited to cases of active arthritis with an increased erythrocyte sedimentation rate, and the dosage should be low and only gradually increased. Modern views are that the dosage should not exceed 0.05 ml. of the usual preparations at weekly intervals for a course of three or four months, and it should be controlled by frequent blood counts, sedimentation rate tests, and urinary examination. To discuss in full the dangers and contraindications would be a lengthy matter, and they will be found set out in any modern book on the management of arthritis and rheumatic diseases. It is generally advisable where possible for the treatment to be initiated under hospital conditions where the necessary preliminary investigations can be carried out. It should be emphasized that it is a potent but sometimes dangerous remedy not to be lightly used.

## Control of Gastric Acidity

**Q.**—It is commonly taught that drugs which paralyse the parasympathetic nerves such as atropine or hyoscine cause a fall in gastric acidity. Is this really true even with full dosage? Could you inform me of any human experiments carried out to investigate this supposed action?

**A.**—Atropine, hyoscyamine, and hyoscine may all lower gastric acidity if given in full doses. The reduction is never profound, and can affect only the "psychic" secretion. This, in relation to peptic ulceration, is relatively unimportant because it is short-lived. Many experiments have been reported in this connexion. (See article by A. H. Douthwaite, *British Medical Journal*, July 12, 1947, p. 43.)

## Cerebral Arteriosclerosis

**Q.**—Eighteen months ago a man aged 50 had a head injury and was unconscious for three weeks. Nine months later he resumed work as vicar of a town parish. He now complains of a feeling of nervous tension in the early part of the day, of being more irritable, of periods of depression, of less ability to concentrate, and of some forgetfulness. He is more talkative than he used to be, and is himself conscious of this. What is the probable prognosis, and is there any particular treatment of value?

**A.**—The symptoms are consistent with a cerebral arteriosclerosis, which may well have been precipitated, or aggravated, by the injury. Full neuropsychiatric testing is advisable, however, especially from the standpoint of excluding (1) early dementia and (2) an affective psychosis.

## Treatment of Urticaria

**Q.**—What are the indications for autohaemotherapy? I refer to the intramuscular injection of 10 ml. of the patient's own blood, freshly withdrawn from a vein. Is it of use in urticaria? Are there likely to be any unpleasant reactions; if so, what form do they take? Are there any other suggestions for the treatment of urticaria apart from ephedrine, "benadryl," and adrenaline, which all provide temporary relief?

**A.**—Autohaemotherapy is sometimes very effective in the treatment of pruritus and urticaria and is sometimes helpful in the treatment of other functional disorders of the skin. It is probably a mild form of shock therapy, but is not associated with any untoward reactions unless they be psychological. All the measures mentioned are forms of symptomatic therapy. Greater success should attend rational therapy directed towards the cause of the urticaria. This may be dietetic, metabolic, toxic, or psychological, to mention some of the more common causes, but the problem calls for full investigation of the patient in relation to these or other environmental factors.

## Low Diastolic Pressure

**Q.**—A female aged 57 has complained of headaches and attacks of dizziness for many years. During one of these attacks she fell backwards and sustained a superficial incised wound of the scalp. On investigation the blood pressure was puzzling: the systolic pressure was 115; the diastolic pressure was present until it registered 0, so that the reading was 115/0 mm. Hg. What is the significance of such a reading and can you suggest any treatment?

**A.**—Very low diastolic pressure, or the persistence of sounds on sphygmomanometry down to zero on the scale, denotes high-grade vasodilatation such as occurs in free aortic regurgitation, arteriovenous aneurysm, and sometimes in patency of the ductus arteriosus. Lesser degrees of the same phenomenon are met with in thyrotoxicosis and neurocirculatory asthenia, including the effort syndrome. If there is a rotatory element in the dizziness the attacks are certainly of labyrinthine origin. Such attacks could occur if an arteriovenous aneurysm involved the circulation to the head. It is well known that aortic valvular disease is commonly associated with syncopal attacks, but in such circumstances vertigo would not be expected. No further speculation is likely to be profitable on the data provided. For full elucidation of the case a complete cardiac survey with electrocardiography and radiological examination would be necessary.

## INCOME TAX

All inquiries will receive an authoritative reply but only a select can be published.

## Appointment Expenses

C. S. asks what claims can be made under the following heads.

(a) Medical subscriptions and periodicals: no claim can be made unless membership of the organization, etc., is a condition attached to the appointment.

(b) A room in the residence exclusively for professional study: no claim.

(c) Use of a car for professional purposes: the running costs and depreciation (25% of the written down value), insurance, licence, repairs, etc., in the proportion which the mileage necessarily run on professional duties bears to the total amount.

(d) Replacement of medical textbooks and instruments: any reasonable expenditure is allowable, provided that the terms of the appointment (express or implied) require C. S. to maintain a medical library and a set of instruments.

C. S.'s earnings are assessable under Schedule E, and the expense rule under that Schedule is a rigid one. To be allowable, expense must be "wholly exclusively and necessarily in the performance of the duties of the employment," and the Courts have drawn fairly sharp distinction between expenses incurred "in the performance" and expenses incurred in order to put the individual in a position to perform them.

## NOTES AND COMMENTS

**Poliomyelitis and Chlorination of Water.**—Dr. HENRY BERN writes: Dr. Clement Francis (Sept. 13, p. 440) writes about chlorination of water and its possible effect on the poliomyelitis crisis. He might be interested to know that in this area—Stair and Egham—the water company have always chlorinated their water very well indeed, in fact to such an extent that there is a definite taste and slight odour of chlorine during the summer months. So far, I am pleased to say, we have been very free from poliomyelitis. There has been only one case, and this boy attended school out of the area, so he could have been infected elsewhere. We have been very surprised at the apparent immunity of the population in this area and have put it down to luck, but perhaps Dr. Francis has hit on something really important.

**Thumb-sucking.**—Lieut.-Col. H. H. KING, C.I.E., I.M.S. (re Leitchworth), writes: Under "Any Questions?" (Sept. 13, p. 43) there was a query about how to prevent thumb-sucking. The questioner might like to hear my suggestions which have worked in another case. Secure the co-operation of the boy by offering reward if he stops the habit, and, to help him stop it, get him wear the finger of a glove on the thumb he sucks. This is to be tied on round his wrist. Thumb-sucking is usually done absently, and the glove finger will stop this by immediately making the boy conscious of what he is doing. Then if he himself is trying to stop the habit he will refrain from pulling the glove off at from sucking his thumb. A little quinine on the glove might also help.

**Chronic Glaucoma.**—Dr. N. W. JENKIN (Hindhead, Surrey) writes: My own experience may be of value to your correspondents in the treatment of chronic glaucoma ("Any Questions?" Sept. 13, p. 404). I am 65 years old, and the condition was discovered this year ago. I have a fair-sized scotoma in the right eye. This eye was trephined three years ago and is now very satisfactory, with good central vision. The left eye has a full field but the tension is dangerously high. It was not controlled by pilocarpine. Eserine 1% kept the tension down applied as drops twice a day. But after a year the conjunctiva became sensitive and the eserine drops had to be discontinued. I now use eserine ointment 3% applied generously at bedtime. This causes no irritation, has a strong miotic action for 24 hours, and keeps the tension below continuously. For me it is the perfect answer. I am in full and vigorous work.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 4 1947

## British Medical Association

### REPORT OF INSURANCE ACTS COMMITTEE, 1947

#### Chairman

Dr. E. A. Gregg was reappointed Chairman of the Committee for the Session 1946-7.

#### Obituary

The Committee regrets to record the deaths of:

Dr. J. W. Hunter (Ipswich), representative of the Society of Medical Officers of Health on the Committee for three years; and Dr. S. E. A. Acheson (Belfast), a representative of Northern Ireland on the Committee for fifteen years, and Secretary of the Central Practitioners Committee for Northern Ireland.

#### Ministry of Health Distribution Committee

The Committee's nominees on the Ministry of Health Distribution Committee in connexion with the Central Practitioners and Mileage Funds are: Dr. E. A. Gregg (London), Dr. D. J. B. Wilson (High Wycombe), Dr. D. B. Evans (Wrexham), and the Assistant Secretary (Dr. L. S. Potter), together with Dr. J. A. Ridham (Weymouth), Dr. J. C. Pearce (Diss, Norfolk), and Dr. J. D. Wells (Billericay), when questions concerning mileage were under consideration.

#### INSURANCE CAPITATION FEE

Although the terms of the settlement of the claim for an increase in the capitation fee are well known to all concerned, this report would not be complete without a brief description of them.

Following the acceptance by the Annual Conference of the Minister's offer of immediate discussions "fully to apply the Spens Report to the current capitation fee with effect from Jan. 1, 1946," representatives of the Insurance Acts Committee (Drs. E. A. Gregg, H. Guy Dain, J. A. Brown, W. M. Knox, J. A. Pridham, and S. Wand) had three lengthy discussions with representatives of the Ministry. Towards the end of the discussions the Ministry made what was indicated to be its final offer of 15s. 6d., after arguing that the appropriate fee should be substantially less. The details of the offer, with effect from Jan. 1, 1946, were:

1. The increase recommended by the Spens Committee, excluding the special measures affecting rural practices, is taken as equivalent to an average for all general practitioners of £162. (This if taken in full would equal 3s. 3d. on the capitation fee.)

2. Of this increase, 90% is accepted by the Ministry as attributable to insurance practice. This figure is based on the view that, while undoubtedly by far the largest part of the underpayment of doctors before the war as found by the Spens Committee is applicable to health insurance remuneration, it is nevertheless fair to attribute a small part of this underpayment to other practice.

3. Allowing betterment at 30% on the gross fee, we get:

	s.	d.
Capitation fee (1939) .. .. .	9	0
Spens increase (90% of 3s. 3d.) .. .. .	2	11
	11	11
Betterment (30%) .. .. .	3	7
	15	6

The "betterment" figure takes account of increases in medical practice expenses and cost of living since 1939.

Coupled with the Ministry's offer was a statement to the effect that in making it the Minister was influenced by the fact that the calculation upon which the figure of 15s. 6d. was based had involved the assessment of factors which were relevant also to the determination of future remuneration and would have a bearing on any future negotiations concerning the new Service.

This offer of 15s. 6d. was not regarded as adequate, but the Committee's representatives undertook to put it before the Committee. Before the Committee met, Panel Committees throughout the country were asked for their views on the Ministry's offer and a large majority of them favoured acceptance but took strong exception to the reservation. After careful consideration the Committee passed the following resolution, which was sent to the Ministry:

"That the Minister's offer of 15s. 6d. as a capitation fee for medical service under the existing National Health Insurance Acts and his proposals for augmenting the Mileage Funds, both retrospective to Jan. 1, 1946, be accepted without prejudice to the remuneration in any future service and to the factors to be employed in its assessment."

#### MILEAGE

The application of the Spens Report to the remuneration of insurance practitioners necessarily meant an increase in the mileage grant, especially in view of the opinion expressed by the Spens Committee that the pre-war difference between the incomes of rural and urban general practitioners should be reduced. The Central Mileage Funds for England, Wales, and Scotland have together received an increase of £236,280 for each of the years 1946 and 1947, making a total overall sum of £615,380, or 94% above the 1939 figure.

This new money has been divided between the two central funds in proportion to the amounts they received in 1939, but it was represented that a proportionate increase in mileage payments to Highlands and Islands doctors would not give these practitioners the increase recommended by the Spens Committee—since their remuneration in 1939 was inadequate compared with that of other practitioners in rural practice. It was suggested that the augmentation of low incomes in very sparsely populated areas like the Highlands and Islands could best be secured by weighting mileage more heavily. After careful consideration by the Insurance Acts Committee and its Rural Practitioners Subcommittee, it was agreed that the special position of insurance practitioners in the Highlands and Islands should be recognized in this way and that an adjustment of the new mileage money should be made to meet the situation. Accordingly it was decided to authorize the transfer of £6,000 for each of the years 1946 and 1947 from the Central Mileage Fund for England and Wales to the Highlands and Islands Fund upon the understanding that a similar transfer of £1,500 for each of the two years would be made from the Scottish Central Mileage Fund.

The Committee felt that a substantial part of the new money for mileage should go to the truly rural practitioner, as distinct from the urban or semirural practitioner who is able to claim "ordinary" mileage for some of his insured patients. The Central Mileage Distribution Committee considered this suggestion, but decided that, having regard to the time it would take to collect data upon which a scientific redistribution of the

mileage grant could be based, the only practicable method of securing higher payments for rural doctors would be to increase the value of the higher mileage units. County Panel Committees have been recommended to consider suitable amendments of local mileage schemes to give effect to this suggestion.

### DISPENSING CAPITATION FEE

The capitation fee paid to doctors in rural areas for supplying ordinary medicines, etc., to insured patients was 2s. 6d. in 1939. Increases of 6d. were obtained in October, 1940, and November, 1945, and negotiations have been completed which result in a further increase of 1s. 3d., with effect from Jan. 1, 1947, making a current fee of 4s. 9d., or 90% above the pre-war fee.

### Higher Capitation Fee for Treatment of Discharged Services Personnel

In reply to an inquiry, the Ministry states that members of His Majesty's Forces who, subsequent to demobilization, are awarded a disability pension, come within the special arrangement for a higher capitation fee. The Ministry has been asked to arrange in such cases for automatic notification to the insurance committee for the area in which the discharged person resides.

### RESIGNATION ISSUE—POSITION OF OTHER SECTIONS OF THE PROFESSION AND CHEMISTS

Recent events in connexion with the insurance capitation fee have prompted two or three Panel Committees to suggest that steps should be taken to secure the co-operation of other sections of the medical profession and the chemists in the event of withdrawal from a publicly organized medical service. One suggestion is that all other sections of the profession should be asked to withdraw from any form of Government service in which they may be engaged. The Committee does not feel that it would be reasonable to support such a proposal.

Another suggestion is that if, in the event of insurance practitioners withdrawing from the National Health Insurance medical service, chemists are instructed to supply medicines and appliances prescribed on unofficial forms, they should be asked to refuse to dispense under the National Health Insurance Act during the emergency. The Committee has promised to bear this suggestion in mind.

### INSURANCE PRACTITIONERS WITH FINANCIAL COMMITMENTS

The Committee was asked by the 1946 Annual Conference (Minute 36) to consider the possibility of assistance being given to medical practitioners who, having borrowed money to buy their practices, find themselves unable to resign from National Health Insurance practice owing to the terms of their agreements with financial agencies. This question is likely to arise in another form if the medical profession is advised not to accept service under the National Health Service Act, and the Council of the British Medical Association has appointed a special committee to consider the problem. The committee has not yet presented its report to the Council.

### CERTIFICATION

An increasing number of employers are requiring National Health Insurance certificates as evidence of incapacity for work. This improper practice has been the subject of representations to the Ministry of Health over a number of years. In the first place it is specifically stated on the official National Health Insurance certificate forms that "These certificates are to be used for National Health Insurance purposes only." Secondly, it is not in the interests of the insured person that he or she should be required to produce an official form. For one thing, the employee cannot comply with the requirement to send it to his Approved Society on the day it is issued if he has to send it to his employer by post. Again, the doctor is obliged to state as precisely as possible the cause of incapacity, and there may be reasons why the insured person does not wish this information to be made known to his employer. He can adopt the expedient of asking the doctor

for a private certificate in less precise terms. But he may not realize this at the time. It has been demonstrated recently that even Government Departments are asking for National Health Insurance certificates to be provided when a member of the staff is absent on account of illness.

The view of the Ministry is that where some certificate is asked for by the employer and the official National Health Insurance certificate is produced no objection can be raised. The Ministry is willing to take action, however, when it can be proved that a Government Department or other employer insists on employees producing the N.H.I. certificate. Panel Committees are asked to send to the Insurance Acts Committee any written or printed evidence of this practice.

The Committee is not impressed by the Ministry's attitude and will continue to protest strongly against the use of official forms of certificate for other than N.H.I. purposes.

### DISPENSING AND PRESCRIBING

#### Capitation Fee for Emergency Drugs and Dressings

The Ministry of Health is being asked to increase the Capitation Fee (varying from 1s. 3d. to 2s. 6d. per 100 insured persons, according to local conditions) at present payable insurance practitioners for the provision of drugs and appliances supplied in an emergency.

#### National War Formulary

A third edition of the *National War Formulary* has recently been issued to insurance practitioners, and came into operation on Oct. 1. When the Ministry made known its intention to continue the use of this formulary the Insurance Acts Committee registered a protest, suggesting that, as insurance practitioners were hampered in their treatment of insured persons by the limitations of the *War Formulary*, an immediate return should be made to the pre-war *National Formulary*.

#### National Health Service Formulary

A Joint Committee of Representatives of the B.M.A. and the Pharmaceutical Society is engaged on the preparation of a formulary for use under the National Health Service Act.

#### N.H.I. Drug Tariff

The Ministry of Health agreed to the Committee's request for a reversion to the pre-war practice of issuing the Drug Tariff to individual insurance practitioners.

#### Chemists' Hours

It is understood that in a few areas difficulty is being experienced owing to the absence of facilities for the dispensing of insurance prescriptions after the usual retailers' closing hour. The Committee is convinced that the only practicable way of settling this problem is by an informal conference of representatives of the local Panel and Pharmaceutical Committee.

#### Schedule of Appliances—Tulle Dressings

Following an application by the Committee for the inclusion of a preparation of sterile vaselined gauze in the Schedule of Appliances, the Committee is informed that the B.P.C. Revision Committee has approved a suitable dressing for inclusion in the *Codex*. This dressing, when available, will be medicated gauze, obtainable as part of medical benefit without amendment of the Schedule of Appliances.

#### Especially Expensive Drugs

Application has been made for the inclusion of several suppositories and the whole range of sulphonamides (including sulphamerazine) in the list of drugs and appliances in Part of the Distribution Scheme, the cost of which does not fall on doctors in respect of their "dispensing" patients. The Ministry is unwilling to make any additions to the list at present, but is prepared to consider applications for special payment in cases where the doctor is involved in heavy expenditure. The Ministry is being asked to reconsider the matter.

#### Shortage of Medicaments

Representations have been made to the Ministry of Health on the shortage of liquid paraffin, olive oil, and glucose. The

shortage of liquid paraffin is stated to be due mainly to the fact that supplies, though up to 1939 volume, are inadequate to meet the present increased demand. Regarding olive oil, the Ministry of Health is continually pressing the Ministry of Food to increase the supply, but the main difficulty appears to be the difference between the price demanded by the supplying countries and the price Great Britain is prepared to offer. The shortage of glucose is a reflection of the world shortage of cereals, and there appears to be little prospect of an immediate improvement.

#### Dispensing for Rural Patients

The Rural Practitioners Subcommittee has been considering a suggestion by Derbyshire (Minute 44 of 1946 Annual Conference) that a drastic reduction in dispensing lists should be effected. The Subcommittee came to the conclusion that this would be impracticable.

The question of the extent to which general practitioners wish to continue dispensing for their patients under the National Health Service was also discussed. There is evidence that many country doctors would be very glad to give up dispensing if satisfactory arrangements could be made to supply medicines and appliances expeditiously through chemists. Those who practise in sparsely populated areas, however, are convinced that, apart from being uneconomical, a service provided by chemists in such areas would be unsatisfactory from the patient's point of view. The delivery of medicines would take longer, and the traditional faith of the countryman in the doctor's dispensing is an important factor. All are agreed on one point—that the remuneration must be adequate for whatever dispensing is required.

#### RURAL MEDICAL PRACTICE UNDER THE NATIONAL HEALTH SERVICE

The Rural Practitioners Subcommittee has discussed the difficulties associated with rural medical practice and has formulated the following points, which must be taken into consideration in the settlement of the terms and conditions of service for general practitioners under the National Health Service:

(1) The field of medical practice in rural areas is restricted on account of distances to be travelled and sparse population.

(2) The strain on physique is greater in rural than in urban practice.

(3) Special emphasis should be placed on the provision of an efficient ambulance service. At present the rural practitioner frequently has to provide the transport when a patient goes to hospital.

(4) The provision of adequate facilities by way of branch surgeries and places of call.

(5) The additional responsibility of the rural practitioner in cases of emergency (road accidents, etc.) owing to the long distance to the nearest hospital.

(6) The burden of dispensing and the delivery of medicines. It is essential that the doctor should be adequately paid for the time spent in dispensing as well as the ingredient cost.

(7) Special expenses, such as higher telephone costs, should be taken into consideration.

(8) The practicability of a special grant for travelling, unrelated to mileage, might be explored.

(9) In place of the suggestion in the Spens report (paragraph 17) that the Highlands and Islands system should be extended to other sparsely populated areas, which is not considered to be practicable in a publicly provided service covering the whole population, the possibility of a special grant, unassociated with mileage, for specified areas might be considered.

#### PATHOLOGICAL FACILITIES FOR INSURED PERSONS

For many years the Committee has been pressing the Ministry of Health to provide a complete pathological service for use by medical practitioners for their insured patients. Believing that such a service would conduce to the economic use of penicillin, a further appeal was made to the Ministry in the autumn of 1946. The Ministry is not prepared to extend the scope of the present National Health Insurance medical service in this way, but has recently announced the introduction of a partial laboratory service which is available to all general practi-

tioners—partial in the sense that, though organized on a regional basis, it has not yet been possible to cover the whole country. It is known as the Public Health Laboratory Service, and is under the direction of the Medical Research Council (for the Ministry of Health). In general it covers all bacteriological examinations in the laboratory and observations in the field in relation to diagnosis, prevention, and control of infectious diseases other than venereal disease. One of its advantages is that it offers an opportunity for consultation with the bacteriologist. Most of the public health laboratories are being absorbed into the service, and the Ministry is anxious that full use shall be made of it. It does not include clinical pathology. The clinical service will be provided by hospitals, organized by the Regional Hospital Board. It is hoped that a closer relationship between the two services will speedily develop. A more detailed description of the laboratory service will appear in an early issue of the *Supplement*.

#### REGIONAL MEDICAL SERVICE

##### Reference of Patients to Specialists

Over the past two years there have been exchanges with the Ministry of Health on the Ministry's attitude in cases where an insured person is examined by a Divisional Medical Officer and a tuberculous condition is diagnosed. The point at issue is whether the patient's own doctor should be given an opportunity of making arrangements for an examination by a specialist. The Ministry's contention is that it would be impracticable—because of the time factor—to leave the arrangements for such an examination in the hands of the patient's doctor in cases where the sole question was the patient's capacity for work. The Ministry agreed, however, that in cases where the opinion of a specialist was considered to be desirable for reasons other than an assessment of the patient's capacity for work, no steps would be taken without consulting the patient's own doctor. The Committee has maintained the view that it is in the interests of insured persons and of the community that doctors should be given every opportunity of discharging their responsibility to their patients and that all visits to consultants and specialists should be made through them or with their concurrence.

The Ministry's last word is a further refusal to meet the Committee's wishes in this matter for the limited time remaining of the present insurance medical service, and a reference to the opportunity which the profession will have of assisting in formulating the procedure to be adopted in the National Health Service for obtaining specialist advice.

##### Examination of Pregnant Women

The question here is the stage of pregnancy during which a woman should not be required to attend an examination centre for examination by a Regional Medical Officer. The Insurance Acts Committee's original request was that a woman should be examined in her own home if she is within eight weeks of the expected date of confinement. The Committee's point is that it is not in the patient's interest that any woman who has reached the thirty-second week of pregnancy should be required to attend an examination centre, whether or not she is physically fit to make the journey.

The Ministry drew attention to the arrangement made in 1935 that no woman who was stated by her doctor to have reached the thirty-sixth week of pregnancy would be summoned to a centre. The Ministry is prepared to extend this arrangement to women who have reached the thirty-fourth week of pregnancy, provided the doctor states, on Form R.M.2, the stage of pregnancy in weeks that has been reached, and indicates that the patient is not fit to attend an examination centre. The Ministry's view is that these arrangements are in line with the provision of the National Insurance Act (1946) for payment of a maternity allowance during the last six weeks of pregnancy.

##### Sickness Benefit in Relation to Pregnancy

At the Committee's request the Ministry of Health approached the Ministry of National Insurance with a view to arranging that in cases where sickness benefit is paid for incapacity for work due to pregnancy the attending doctor would not be required to give more than one certificate to

cover the whole period. The Ministry of National Insurance indicated that it could not agree to this proposal.

As an alternative the Committee asked that in cases where a doctor is satisfied that his patient will not be capable of work until after her confinement, he should be allowed to issue a special intermediate certificate (Form Med. 40B) without waiting for the qualifying period of twenty-eight days to elapse. The Ministry's reply is that, even if the desired amendment of the medical certification rules did not present serious difficulties, the introduction of a special long-term certificate of incapacity for pregnancy cases would not result in more than a very small saving of clerical work to individual doctors, as the patients concerned would normally continue to be seen at weekly or other fairly short intervals. The Ministry goes on to say that, under the provision of the National Insurance Act, certificates of incapacity will not be required during the material six weeks before confinement. The Committee is still not satisfied with the reasons given for the refusal to accede to its request, and is pursuing this question further with the Ministry.

### LIMITATION OF LISTS

At the beginning of the war the Ministry sanctioned a temporary addition of 500 to the maximum number of insured persons that a single-handed practitioner was allowed to have on his list, with corresponding increases for those in partnership and where assistants were employed. At the end of 1946 a decision in favour of reversion to the pre-war maxima was taken. The directive issued by the Ministry was carried out in some areas without regard to special circumstances and did not take account of increases approved when juveniles were added to the insured population. A further directive made it clear that these approvals would remain in force and that applications from other Insurance Committees for similar concessions, as well as for increases occasioned by the extension of medical benefit to non-manual workers with incomes up to £420 per annum, would be considered favourably.

### NEW ENTRANTS INTO INSURANCE

It was suggested by the Bristol Panel Committee at the last Annual Conference (Minute 39) that a new contribution card should be provided with a detachable section which would contain the particulars at present asked for on Form Med. 50 and a space for the employer's signature. The insured person would be instructed to present the detachable section to his doctor at once, and this would take the place of the medical card until the latter is received from the Insurance Committee. This proposal has been passed on to the Ministry of Health with the suggestion that it might be useful in an appropriate form under the National Health Service.

### SURVEY OF ELDERLY INSURED PERSONS

In some areas insurance practitioners are being asked to assist the Insurance Committee to trace insured persons who were 70 years of age or more on Jan. 2, 1928, by giving any information that may be in the doctor's possession. The question has been raised as to whether this is likely to form a precedent for similar information which may be required under the National Health Service. The Committee favours co-operation with Insurance Committees in this matter, believing that the safeguarding of the future position can be left with confidence to the body which will take its place under this new Service.

### POSTGRADUATE COURSES FOR INSURANCE PRACTITIONERS

The Ministry of Health has reintroduced postgraduate courses for insurance practitioners on the lines of similar courses available in 1938-9, pending the provision of such facilities under the proposed National Health Service. The resumption of these courses was made possible by the willingness on the part of the universities to continue during 1947 the courses of postgraduate instruction for demobilized doctors.

An insurance practitioner is given freedom of choice of the centres where courses are available, and financial assistance towards his expenses in connexion with the course will be paid out of National Health Insurance funds. Such expenses will include a grant for the provision of a locum tenent (maxi-

mum fourteen guineas), where necessary; the fee for the course subsistence allowance while attending the course, and actual first-class travelling expenses.

### RECRUITMENT OF DOCTORS—PROTECTION OF PRACTICES

The Committee was asked by the 1946 Annual Conference (Minute 49) to consider whether any hardship exists among doctors who are being called up for the Forces either as specialists or as general duty officers; and, if so, whether any steps should be taken to meet the position, possibly on lines similar to the wartime protection-of-practises arrangement. It is understood that the number of doctors in general practice now being compulsorily recruited is extremely small, and it is doubtful whether the situation calls for any wide spread protection-of-practises arrangement. The Committee feels that the interests of general practitioners are being carefully watched by their colleagues on Local Medical War Committees and by the Services Committee of the Central Medical War Committee, and that satisfactory arrangements of an *ad hoc* nature could be made for the protection of the practice of a doctor who is in need of such assistance.

### EXAMINATIONS BY MASS MINIATURE RADIOGRAPHY

The Ministry of Health was asked to arrange that in all cases where persons are examined by mass miniature radiography and the taking of a full-size skiagram is subsequently found to be necessary, the findings, whether positive or negative, would be communicated to the person's own doctor. It was contended that even in cases of a negative finding it was desirable that the doctor should be in a position to reassure the patient, and that it would be a valuable item in the patient's medical record. The Ministry has asked authorities operating mass radiography units to notify the result of the examination to all persons examined so that they may inform their own doctors on the next occasion on which they need medical attention. The Committee is still not satisfied and is continuing discussions with the Ministry.

### NATIONAL INSURANCE DEFENCE TRUST

The balance-sheet and statement of expenditure and income of the Trust for the year ending Dec. 31, 1946, are being sent to every Panel Committee.

The 1946 Annual Conference urged every Panel Committee to complete its quota to the Trust without delay. This appeal was followed by a communication to all Panel Committees with advice on how the object could be achieved, and copies of a statement on what the Trust is and how it works were sent to each Panel Committee for circulation to its constituents.

The response to this appeal is summarized in a separate document which is being sent to Panel Committees. Most of them have initiated action which is resulting in a substantial increase in the income of the Trust. Some Committees are doubtful about the need for a large fund of this description under the proposed National Health Service. The trustees do not share this doubt, believing as they do that the need for a strong fund will be greater than ever. Others feel that non-insurance practitioners should be brought into the fund, but it has been pointed out that until a decision to enter the new service has been reached it would be premature to attempt to bring them in.

The trustees wish to pay tribute to three Panel Committees which are the first to complete their quotas—West Bromwich (£2,055), Durham (£17,821), and Warrington (£1,940), in the order of their doing so.

### SCOTLAND

This particular section deals with matters which are of a purely domestic Scottish nature and which have not been referred to in the preceding paragraphs, or upon which action in England and Wales differs from that taken in Scotland.

#### Chairman and Deputy Chairman

Dr. A. F. Wilkie Millar and Dr. W. M. Knox were appointed Chairman and Deputy Chairman of the Scottish Subcommittee respectively for Session 1946-7.

**Advisory Distribution Committee of the Department of Health**

The following were reappointed as nominees of the Scottish subcommittee on the Advisory Distribution Committee: Dr. F. Wilkie Millar (Edinburgh), Dr. John Lambie (Glasgow), Mr. Robert Bruce (Culter), and the Scottish Secretary.

**Medical Advisory Committee**

The Department of Health was informed that all members of the Scottish Subcommittee would be available for service on Medical Advisory Committees constituted under the Medical Benefit Regulations (Scotland), 1938.

**Allocation of Additional Moneys following the 1946 Negotiations**

In February last a joint meeting of the I.A.S.C. and the Highlands and Islands Subcommittee of the Scottish Committee had under simultaneous consideration the Ministry of Health's proposals for the division between England and Scotland of the additional mileage grants (made available following acceptance of the Spens Report) and those of the Department of Health concerning revision of the Highlands and Islands grants. As a result it became apparent that if the distribution proposals were carried into effect without modification the proportion of the total sum which would be available for the Highlands and Islands doctors as a group would fall considerably short of that indicated in the Spens Committee's recommendations. The difficulty was brought to the attention of the Insurance Acts Committee and, following consultation with the Rural Practitioners Committee in both countries, it was decided to recommend to the Ministry that £7,500 should be paid into the Highlands and Islands Fund, of which £6,000 would be contributed from the English and £1,500 from the Scottish portions of the £236,000 distributable. The Highlands and Islands doctors have expressed their appreciation of this fair-minded action of their rural colleagues in both countries.

**Rural Practitioners Subcommittee**

The Rural Practitioners Subcommittee was reconstituted with Dr. Robert Bruce (Aberdeenshire) as Chairman.

**Remuneration of Dispensing Doctors**

The Subcommittee has considered the question of the substitution of a national rate for dispensing doctors in Scotland in the lines of that in operation in England for the existing method, where these doctors are paid according to the chemist's rate for the area. The argument advanced in support of the adoption of a national rate was that the cost of supplying expensive drugs would be covered and there would be no risk of patients being deprived of an essential remedy. In the view of the Subcommittee, however, against any such advantage must be offset the fact (i) that under the present system the cost of penicillin, liver extract, and insulin was already covered, and claim could be made for repayment in respect of any other especially expensive drug required over a long period; (ii) that owing to the differences in prescribing in the two countries—namely, 2 prescriptions per person per annum in Scotland, as compared with 4.4 in England—the national rate would be lower in Scotland—approximately 3s. as compared with 4s. 9d. in England. Such a rate would compare unfavourably on the average with the present area rate. Dispensing doctors consulted by members of the Subcommittee had expressed the view that the existing method of payment worked well and was on the whole equitable, and there was no desire to change to a national rate at the present time. This view is supported by the Subcommittee, and accordingly no action has been taken for variation at this stage of the system of payment.

**Health Centres in Rural Areas**

The Subcommittee has also considered the most useful type of Health Centre in rural areas under the National Health Service (Scotland). The view of the Subcommittee is that in rural areas a system of Health Centres in the sense of grouped surgeries is impracticable: centres should be developed on the lines of the cottage hospital, which would, *inter alia*, provide facilities for diagnosis, treatment by practitioners of those of

their patients who require hospitalization but not specialist treatment, physiotherapy, dental treatment, and maternity services. Provision should also be made for clerical assistance for the practitioners.

**Central Mileage Fund, 1946**

The attention of the Local Medical and Panel Committees in Scotland has been drawn to the desirability of action being taken to secure the implementation of the principle enunciated in the Spens Report that rural insurance practitioners should derive the greatest benefit from the increase in the Mileage Fund in respect of 1946. Secretaries of these Committees have been advised that, where necessary, approach should be made to the Insurance Committee with a view to securing appropriate adjustment to the area Mileage Scheme, and the following possible methods of approach have been suggested as a guide to the Committees: (a) stepping up the unit allowance for high mileage—e.g., four or more units for each mile over 5; (b) where schemes provide for percentage reduction in relation to numbers on doctors' lists, steeper grading of these reductions; (c) a combination of these methods.

**Drug Accounts Committee (Scotland)**

The Subcommittee has considered difficulties experienced by the Checking Bureau in preparing its accounts. An increasing number of practitioners are prescribing the quantities for an individual dose instead of quantities for the total prescription. Again, an increasing number of prescriptions have ingredient quantities written in metric weights and measures but total quantities written in terms of apothecaries' weights and measures. The attention of Panel Committees has been drawn to these difficulties, and they have been asked to co-operate in overcoming them.

**RELEASE OF MEDICAL OFFICERS FROM H.M. FORCES**

The following is the latest information received by the Central Medical War Committee regarding the release in Class A of medical officers from H.M. Forces.

**Royal Navy**

The Admiralty states that this programme is tentative and may require amendment.

Oct. 1–Nov. 30, 1947: Group 64; Dec. 1–Dec. 31, 1947: Group 65.

**Royal Army Medical Corps**

(a) *General Duty Officers*.—Oct. 1–Nov. 15, 1947: Group 62; Nov. 16–Dec. 31, 1947: Group 63.

(b) *All Specialist Medical Officers*.—Oct. 1–Oct. 31, 1947: Group 54.

(c) *Physicians and Surgeons only*.—Nov. 1–Nov. 15, 1947: Group 55; Nov. 16–Nov. 30, 1947: Group 56; Dec. 1–Dec. 15, 1947: Group 57; Dec. 16–Dec. 31, 1947: Group 58.

(d) *Specialists other than Physicians and Surgeons*.—Nov. 1–Nov. 30, 1947: Group 55; Dec. 1–Dec. 31, 1947: Group 56.

**Royal Air Force**

Oct. 1–Oct. 31, 1947: Group 63; Nov. 1–Nov. 30, 1947: no release.

**TRADE UNION MEMBERSHIP**

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*County Borough Councils*.—Barnsley, Barrow-in-Furness, Gateshead.

*Metropolitan Borough Councils*.—Finsbury, Fulham, Hackney, Poplar.

*Non-County Borough Councils*.—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, WallSEND.

*Urban District Councils*.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

*Scottish Burghs*.—Motherwell, Wishaw.

## HEARD AT HEADQUARTERS

### Committee Work

A formidable list of Council and committee meetings for 1947-8 has been issued from Headquarters. During October alone the committee meetings at B.M.A. House number 27, not to speak of a Council meeting and the Panel Conference. Altogether, reckoning not only standing committees, which have fixed dates, but special committees and joint committees, which meet as occasion requires, there must be as many as 180 committee meetings in a year, one for every other day, and this leaves out of account subcommittees and drafting committees and all the other little off-shoots of committee procedure.

### A General Practitioner's Contribution

At the International Conference of Physicians which was held in London last month one of the longest rounds of acclamation greeted the contribution of a general practitioner—perhaps the only general practitioner to take any conspicuous part in the Conference. This was Dr. W. N. Pickles, who related his experiences of infective hepatitis as he had encountered it in his general practice at Aysgarth, in Yorkshire. Lord Moran, who presided, said that Dr. Pickles had shown once more how a first-class piece of epidemiological study could be carried out under general practice conditions. Dr. Pickles began his contribution modestly by speaking of a friend of his, aged 5, an intelligent child who could read and write a little, play music a little, and so on. When he was asked if he would not soon be going to school the little fellow said: "I don't need to go to school. I know it all." Dr. Pickles said that when in 1910 he went as assistant in a large country practice in Yorkshire he thought he "knew it all," and he quickly got some shocks. One of these was the occurrence of what was to him at that time an entirely new epidemic disease.

### Senior Past President

Those who can cast their minds back for twenty-one years to the highly successful Annual Meeting in Nottingham in 1926 will remember the dignity and aptitude with which Mr. R. G. Hogarth presided on that occasion and will be interested in the announcement that this month he and Mrs. Hogarth celebrate their golden wedding. Mr. Hogarth began his career as the first house-surgeon to the late Sir Anthony Bowlby, and one of the recollections of Nottingham is of seeing Sir Anthony an interested auditor on the occasion of Mr. Hogarth's presidential address. In that address, in which he said that to be president of the British Medical Association was to be president of the finest association in the world, Mr. Hogarth dealt largely with the pay-bed system in hospitals, a subject which was then exciting a good deal of attention. He himself was chiefly responsible for building and equipping a pay-bed wing at the Nottingham General Hospital, a hospital where he began his service as senior resident medical officer 53 years ago. Mr. Hogarth, who is now 80, still lives in the Ropewalk. He is the senior surviving Past President of the Association.

### Foreign Visitors

The Great Hall and the forecourt of B.M.A. House were filled during the week Sept. 15-20 with people from almost all the countries of Europe and America. The Great Hall has rarely seen such a foreign invasion before. The International Congress of Surgeons was booked to hold its sessions at University College, five minutes' walk away, but such large numbers attended that the theatre there was inconveniently crowded, and an adjournment was made to the Great Hall; even there many had to stand throughout some of the proceedings. For the greater part of a week the walls resounded to French, Italian, and Spanish oratory, with an occasional voice speaking English or American, until one had to reassure oneself by looking at the pillars and flags of Lutyens's hall that one was in England and had not somehow gone abroad without any tourist allowance. The French have a curious way of conducting their discussions.

They collect in advance a large number of names—perhaps thirty or forty—of those who wish to take part in discussion on a paper, and call on them in quick rotation, and not half of them answer when they are called. One name—that of a British surgeon by the way—figured in the list of speakers in every one of the nine discussions, and not once did he appear when his name was reached. In this international assembly they had the same procedure as is so often seen in English gatherings whereby a time limit for speakers is laid down in advance and is disregarded by everybody without rebuke.

### AGREED SCALES OF REMUNERATION

*We published in the "Supplement" of March 22 (p. 37) a circular from the associations of local authorities to their member authorities recommending the adoption of the scale of fees agreed with the B.M.A. for medical practitioners employed on a sessional and case basis. Agreement on one point had still to be reached—namely, the payment of mileage allowance to general practitioners doing sessional work. This has now been settled, and on Sept. 19 the local authority associations sent the following circular to local authorities in England and Wales.*

#### Remuneration of Medical Practitioners Employed by Local Authorities on a Sessional or Case Basis

County Councils Association, Association of Municipal Corporations, Urban District Councils Association, Rural District Councils Association, Association of Education Committees, Mental Hospitals Association.

Dear Sir,

During the course of the negotiations referred to in the letter of Feb. 28, 1947, on this subject, the British Medical Association pointed out that, in the case of general practitioner a mileage allowance had only been included for diphtheria immunization and then only in exceptional cases. They maintained that there would be other exceptions, particularly in rural areas, where the mileage allowance would be justified as they asked for a more general provision in the agreement. The point raised by the British Medical Association was taken after agreement had been reached on the remuneration of medical practitioners as set out in the memorandum enclosed with the joint letter of Feb. 28, and the associations of local authorities took the view that instructions would have to be obtained upon it before it could be agreed.

In due course the following proposal was put to the associations of local authorities, namely, "a mileage allowance (as specified in the scale) should be paid to a general practitioner when travelling to a clinic in a rural area expressly for the purpose of a work of a clinic outside the area of a general practitioner's own practice." This proposal has been accepted by the associations of local authorities save that the Rural District Councils Association are only willing to recommend that the allowance for general practitioners should be the scale appropriate to the county.

The British Medical Association are prepared to accept the position as set out above, the reservation of the Rural District Councils Association being applicable only in the case of rural district councils. The operative date for the commencement of this additional arrangement is Oct. 1, 1947.

Yours faithfully,

G. H. BANWELL,  
Secretary, Association of Municipal  
Corporations.

JOHN J. MCINTYRE,  
Secretary, Rural District Councils  
Association.

S. M. JOHNSON,  
Secretary, County Councils  
Association.

W. P. ALEXANDER,  
Secretary, Association of Education  
Committees.

ARTHUR J. LEES,  
Secretary, Urban District Councils  
Association.

L. T. FELDON,  
Secretary, Mental Hospitals  
Association.

The Duke of Somerset recently opened the Bradford District Hospital at the home of the late Lord Fitzmaurice near Bradford-on-Avon, Wiltshire. Dr. C. E. S. Flemming said that the people of Bradford-on-Avon and district had contributed to the purchase of the building and to its conversion into a modern hospital.

## Correspondence

### Working Hours in the N.H.S.

SIR,—There have been many letters recently in the *Journal* expressing indignation because the A.R.M. turned down the motion by Paddington which said:

That in any National Health Service adequate provision shall be made for a rota of practitioners for duty at night, week-ends, holidays, and during sickness.

I think what the indignant writers fail to realize is that the reason this was defeated was that the meeting did not wish the Ministry to so control general practice, not that they did not think such leisure desirable.

In fact such a scheme has been working for years in my own area in relation to night duty, Sundays, holidays, and sickness, and has recently been extended to regular week-ends. All this has been done by the doctors (some forty in number) without any central direction. It has been done voluntarily without any compulsion, and is now spreading to the whole of the 500 general practitioners in Birmingham. The area includes partnerships and single practices. There is one essential in the establishment of such a system—namely, the good will and friendship of the doctors working the scheme.

Might I with all humility suggest that the malcontents get on with the job and get their schemes arranged *before* any new national health service comes into being?—I am, etc.,

Solihull, Warwickshire.

ARTHUR BEAUCHAMP.

SIR,—In recent issues of the *Supplement* letters have been published from Drs. H. Dakin (Aug. 16, p. 54), Joseph Bell, D. W. Mayman (Aug. 30, p. 63), and others disapproving the action taken by the A.R.M. last July when motions regarding working hours in the National Health Service were defeated. As one of those present at the meeting I feel that the reason for the rejection of the motions may not have been fully appreciated. Representatives were in no way opposed to a rota system which would give doctors reasonable time off for rest and leisure, but they were strongly opposed to the suggestion that the State, or its delegated authority, should organize that rota system for us.

Do we, in fact, wish to be told by bureaucrats when we are to work and when we are to rest? Have we no desire to exercise any choice of the doctor who will deputize in our absence? Some of us are independent enough to prefer to make our own arrangements. Speaking from personal experience in a single-handed practice, it is quite possible to make satisfactory arrangements for half-days and holidays with fellow practitioners, and such co-operation fosters a spirit of friendliness and good will.—I am, etc.,

Stanmore, Middlesex.

H. B. WOODHOUSE.

SIR,—In these days of paper shortage I am amazed that you can find space in the *Journal* for so many letters from the protagonists of the 24-hour day and 7-day week for the medical profession. The effusions of these elderly fifth columnists are doubtless being read with glee by Mr. Aneurin Bevan, who will be encouraged to turn the screw a little tighter even than he had planned when the conditions of service in the State scheme come to be revealed. What serried ranks of sanctimonious humbugs appear to be in the medical profession among the older practitioners, many of whom are considering retirement to escape the rigours of the State Medical Service.

Dr. C. Grantham-Hill (*Supplement*, Sept. 13, p. 67) regards with horror the possibility of medical practitioners' demanding time and a half for Sunday calls and double time for night work. From the depths of my depravity I humbly confess that I think this arrangement is long overdue and should be pressed for to the utmost when conditions of service are being discussed with Mr. Bevan.—I am, etc.,

Grimsby, Lincs.

W. R. HENDERSON.

SIR,—May I add my support to those doctors who have written protesting against the proposal that we should continue to stay on duty 24 hours per day when the N.H.S. is established. As far

as I can see one of the few benefits to the doctor in such a service is that he will have the opportunity to have decent leisure time. The idea of a pension on retirement is very comforting, but when one recalls that many doctors in G.P. work 80 or more hours a week one wonders how many of them will live to receive their pensions or have decent health when they do retire. It amazes me that it could be suggested even that we should stay on duty the clock round, and that the A.R.M. should uphold the proposal baffles me. To accept it means that we are willing to work harder for, probably, less money; for less than a year from the Service becoming fact we still have no idea of our terms of service or our pay. We know that to idealists in the Government the latter point is a mere detail, but it is nevertheless still of considerable importance to many of us, and I suggest that the Minister of Health be told this in no uncertain fashion now, with a request for a satisfactory answer to be quickly given.

—I am, etc.,

Hull.

W. M. GIBSON.

SIR,—I would like to give my full support to those letters in recent issues advocating regular working hours in the proposed National Health Service. We have now a good opportunity to change the most unsatisfactory conditions for general practice. Some attempt should be made by the medical profession to arrange more normal hours of work and leisure for its members. Only exceptional men can turn out good work in any of the 24 hours of the day, seven days a week, even though this is what the Representative Meeting, and probably the rest of the community, seem to expect.

Unless the planners produce definite prospects of a better deal for doctors, I for one will not enter general practice either as it is now or if State controlled.—I am, etc.,

R.N.V.R.

### National Health Service

SIR,—I heartily agree with Dr. J. J. Rohan's letter (*Supplement*, Sept. 20, p. 74). I have repeatedly stated at B.M.A. meetings that it is impossible for general practitioners (the alleged backbone of the profession) to form any conception of a national health service until conditions of service, remuneration, and hours of service are at least discussed. Again I heartily agree with Dr. J. F. Flanagan's letter (*ibid.*). Surely the reason the A.R.M. turned down the motion for fixed hours was entirely due to mass hypocrisy. Does the hierarchy of the B.M.A. really expect doctors in the future to overwork themselves for the miserly remuneration which the Government will offer? And if it is not miserly in the first instance that will only be in the nature of a sprat to catch a mackerel, and in a few months' time some Order in Council will be issued to reduce the pay of doctors on account of the state of the national finances. Bear in mind that the doctors will be ordered to accept less, but the miners—or their like—will not be even asked.

Another probable reason the A.R.M. turned down this motion was fear of the Press. It is time our leaders stood out boldly for the profession and were not always looking to see how the public or the Government would respond to such and such statement. The public, presumably, have Parliament to attend to their interests; the Government can well look after its own. Our leaders, however, are apparently prepared to sacrifice the majority of the profession in order to stand well with the Government, public, and Press. I might add that the net result is that the profession at the moment stands well with nobody.

After all, why did we take up medicine? Surely to obtain a living in that branch of life that most interested us. The great majority of us entered the profession after years of toil so that we could earn enough to live in comparative comfort and educate our children as we so desired. We did not enter it to treat the sick and suffering regardless of remuneration. Let us be honest with ourselves and keep those facts before our eyes and not prate all day about the doctor-patient relationship. In private practice we are able to earn enough to satisfy our very modest desires (or we were before the incidence of the present crushing taxation), subject to the fact that we gave a 24-hour service to our patients—and a very good service indeed in the vast majority of cases. If on the other hand we are pitchforked into that awful sea of contract practice, without any private practice wherein to assert our freedom and individuality, our incomes, at least in residential and rural areas, will be

diminished, but not our hours of work. Is that reasonable? Personally I detest the whole idea of being under a contract to treat all my patients, and I can foresee the time, not very far distant, when the patients will also suffer as well as us, not financially but sociologically.—I am, etc.,

East Grinstead, Sussex.

A. C. SOMMERVILLE.

### The Negotiations

SIR,—It is high time that the B.M.A. dropped this veil of secrecy which has hung over Tavistock House since the negotiations began in February and told us: (a) Whether or not we are to be forced into the National Health Service without any knowledge of the intended conditions of work, hours, pay, etc.; (b) whether or not we are to be given another opportunity to vote on the Service, and, if so, when; (c) whether or not we are to accept the Minister's refusal to appoint more than 5% of those representatives nominated by us on the various committees.

The whole matter is very urgent, and these conditions of silence and drift lead one to conclude that the B.M.A. too has come under the veto. It does seem highly important that those designing the Health Service should make sure that the doctors will enter it before going too far with its preparation. May I also suggest that the "compensation of £50,000,000-odd" would be much better employed in bolstering up the nation's general finances at the present time rather than the so-called morale of the profession.—I am, etc.,

Burton-on-Trent.

J. R. SALMOND.

### Dispensers in N.H.S.

SIR,—May I, through your columns, thank Dr. Reginald R. Halsall (Sept. 13, p. 68) for his concern on our behalf. We, the Apothecaries Hall dispensers, appear to have been either ignored or overlooked in the new State Service. I suppose we are still considered by some people as "those people who take the bread-and-butter out of the mouths of chemists."—I am, etc.,

"ONE OF THEM."

### Representation

SIR,—I see in the *B.M.J.* (Supplement, Sept. 13, p. 65) that Local Medical and Panel Committees are due to nominate direct representatives on the Insurance Acts Committee, and that voters in this election are the individual members of the committees. May I bring to your attention the fact that these committees are not, in some areas, representative of the profession, as they were elected before the last war? Thus many of us have had no opportunity to choose our Local Committees. May I also remind you that a few months ago these same committees nominated and elected members of the Executive Committees set up under the new N.H.S. Act?

Surely at a time like this, when we are all anxiously viewing more and more encroachments on our liberty, the profession should be particularly careful to keep its own house in order. Yet here we have bodies elected about nine years ago, who have retained themselves in office, and are performing functions which were never contemplated when they were formed.

Is this democracy?—I am, etc.,

Shoreham-by-Sea, Sussex.

J. MICHAEL JONES.

### Suspension of Basic Petrol

SIR,—*Re* basic petrol: it is time doctors put their claim for special treatment before the public. The miners have focused attention on the dangerous and exacting nature of their work and have successfully obtained prerogatives. The dangerous and exacting nature of a doctor's work must be equally made public if our life is to remain tolerable in the modern socialized State.

A doctor on call 24 hours a day handling increasing numbers of psychological cases—neurotics—as well as the responsible nature of his work, is subject to great nervous strain, which in many cases leads to a breakdown in health and puts the doctor high in the insurance companies' list of bad risks. To get the necessary relaxation to preserve his health and sanity a doctor needs to get away from his practice at least one afternoon a week and get out in the open air. As one of your correspondents says, this is quite impossible without a car. Owing to his limited spare time and liability to sudden recall, it is impossible

to use the ordinary public conveyances, at any rate until such time as we are working on a 40-hours-a-week basis.

I suggest that a deputation should see the Ministry of Transport to put our case, and, failing satisfaction, a meeting be called at Headquarters to draw up a plan of campaign. Believe me it only needs some such action by a section of the community to set the whole middle or oppressed classes in revolt. I believe we could retain our basic ration by concerted action and prove our strength for the many fights we are likely to have after the "appointed day." By insisting on justice for ourselves we would earn the gratitude of the nation—and, if not, what matter? Do the miners care?—I am, etc.,

W. B. PEMBERTON,

London, S.E.1.

Chairman and Representative, Camberwell Division

SIR,—Very properly some of your correspondents raise the issue of the effect of the withdrawal of the basic ration on their professional leisure. There is another aspect which should be covered by an authoritative opinion from Council—viz., the use of cars to attend meetings of the Association, especially meetings of the Branch Council.

In the Provinces often long distances have to be covered to the meeting place, and if the Association cannot secure a rule permitting the use of one's car the work of the Association bound to be very greatly hampered, and such meetings as held will necessarily be less representative. I should be glad through the medium of the *Journal*, to secure widest public to learn that officers of the Association will not be hampered their work.—I am, etc.,

WM. PARKER,

Swansea.

Secretary, Swansea Division

## Association Notices

### AREAS OF MID-ESSEX AND SOUTH-EAST ESSEX DIVISIONS

Notice is hereby given by the Council to all concerned that it is proposed to transfer the urban district of Burnham-on-Crou and the rural districts of Southminster and Bradwell-on-Sea from the area of the South-east Essex Division to that of the Mid Essex Division. Any member affected by this proposal and objecting thereto is requested to write to the Secretary of the Association by Nov. 1, 1947, stating the objection and the ground therefor.

CHARLES HILL,  
Secretary.

### Branch and Division Meetings to be Held

ISLE OF WIGHT DIVISION.—At St. Mary's Hospital, Newport Sunday, Oct. 5, 3 p.m. Film: Early Diagnosis of Anterior Poliomyelitis, followed by a discussion on Health Centres to be opened by Dr. W. S. Wallace. All island practitioners are invited to attend both the film and the discussion.

STOCKTON DIVISION.—At Stockton and Thornaby Hospital, Barmston, field Lane, Stockton-on-Tees, Monday, Oct. 6, 8.30 p.m. Scientific meeting. Prof. J. C. Spence: An Outline of Paediatric Knowledge necessary for the conduct of general medical practice.

### Meetings of Branches and Divisions

#### WANDSWORTH DIVISION

The Ministry of Health film "The Early Diagnosis of Anterior Poliomyelitis" was shown to a meeting of Wandsworth and Battersea medical practitioners at St. James' Hospital, Balham on Sept. 12. The film was introduced by the chairman, Dr. Harecourt Ellis, and was followed by a discussion on the subject opened by Dr. J. S. Anderson, Medical Superintendent, Groves Hospital for Infectious Diseases, who gave an account of the cases under his care and also answered numerous questions. A vote of thanks to all who had contributed to the success of the meeting was proposed by Dr. H. Alexander.

#### WORCESTER AND BROMSGROVE DIVISION

A special meeting of the Division was held in the Worcester Royal Infirmary on Sept. 2, when the Ministry of Health's film "The Early Diagnosis of Acute Anterior Poliomyelitis" was shown. Dr. R. S. MacArthur was in the chair. After the film an interesting discussion took place, opened by Dr. Brian Gaunt, Medical Superintendent of Hill Top Isolation Hospital, who described the cases admitted to the hospital during the present epidemic. Other speakers were Dr. Wyndham Parker, County Medical Officer, Dr. Corlett, Medical Superintendent of Hayley Green Isolation Hospital. Before the meeting adjourned the film was shown again and a vote of thanks to Dr. Gaunt was proposed by Dr. MacArthur and carried with acclamation.

## PENICILLIN IN NEUROSYPHILIS\*

BY

C. WORSTER-DROUGHT, M.A., M.D., F.R.C.P.

*Physician, West End Hospital for Nervous Diseases and Metropolitan Hospital*

### General Observations

Penicillin, introduced into therapeutics in 1941, was at first restricted to the treatment of certain specified infections. This limitation was by Government direction, and was mainly due to the necessity for conserving the somewhat scanty supplies. It is only within the last year that penicillin has become available for more general use, and especially for experimental therapeutics. Nevertheless, penicillin already has an established place in the treatment of neurosyphilis. It was recognized quite early that the substance had a definite antispirochaetal action, and in 1943 Mahoney, Arnold, and Harris published the results of treating a series of cases of early syphilis with penicillin. From these and the subsequent observations of other workers it became apparent that the immediate results of treatment with penicillin in early syphilis equalled if they did not exceed those obtained with intensive arsenical and bismuth therapy. Further, there was the added advantage that with penicillin there was little or no risk of toxic reactions. Subsequently, rapid improvement in both the clinical condition and the cerebrospinal fluid changes in various forms of late syphilis was reported.

From the follow-up of cases of early syphilis treated with penicillin alone; however, it became apparent that a moderately high rate of relapse occurred. In addition, it was noted that the percentage of cases relapsing was roughly inversely proportional to the total dosage of penicillin given, in the earlier cases treated this had no doubt been inadequate. These observations finally determined what was considered an optimal total dosage expressed in so many Oxford (now international) units. By June, 1944, penicillin was adopted as the "drug of choice" for the treatment of early syphilis in the U.S. Army in Europe, and, in the autumn of 1944, in the Royal Navy, R.A.F., and the British Army. The standard course was fixed at a total dosage of 2,400,000 units given in doses of 40,000 units every three hours, day and night (60 injections), over a period of seven and a half days. Even with this dosage the average relapse rate in early syphilis appears to have been as high as 15% in some series of cases (Marshall, 1946; King, 1946), while others report an 8% (Marshall, 1946) and 7% (Moore, 1945) relapse rate.

### Dosage and Methods of Administration

Most of the present-day experiences of penicillin in neurosyphilis are based on the results of a dosage and a frequency of administration similar to those of the standard

course referred to above. From subsequent variations of dosage, however, it is clear that we still have much to learn in order to evolve the most satisfactory method of applying penicillin, especially in the treatment of neurosyphilis.

Many authorities have considered it advisable, if not essential, that the concentration of penicillin in the blood should be kept at as high a continuous level as possible throughout the period of treatment. It was found that penicillin disappeared from the blood after four hours from the time of injection. The level of penicillin in the blood therefore could be kept up either by a continuous drip technique or by an intravenous, intramuscular, or subcutaneous injection given every three hours, the average period of treatment required to reach an adequate total dosage being seven and a half to eight days.

Intravenous penicillin therapy has little to commend it. The continuous drip technique is inconvenient, troublesome, and needs special apparatus, while even with repeated single intravenous injections there is a risk of thrombophlebitis (Kolodny and Denhoff, 1946). On the other hand, three-hourly intramuscular injections of penicillin in adequate doses yield equally good if not better clinical results than those following intravenous treatment. Thus, according to Mahoney and his co-workers (1944), relapse was more frequent after penicillin treatment given by intravenous injection (including continuous intravenous drip) than by repeated intramuscular injection.

The recent tendency is towards the administration of a somewhat larger total dosage of penicillin in neurosyphilis. Several authors (e.g., Olansky and Chinn, 1946; Marshall, 1946) advocate a total dosage of 4,000,000 units given in repeated intramuscular doses of 40,000 units every three hours.

Some authors consider that it may not be necessary to keep a measurable level of penicillin in the blood constantly throughout the period of treatment, but that equally good therapeutic effects might be obtained by administering much larger doses at considerably longer intervals—for example, twenty-four hours—until an adequate total dosage is reached. Thus Lloyd-Jones and Maitland (1945) state that single doses of from 300,000 to 500,000 units given daily for eight to fourteen days yield equivalent therapeutic results to those following the usual standard course—namely, 60 injections of 40,000 units given every three hours—although no trace of penicillin can be detected in the blood twelve hours after the massive injection.

I have treated some cases of meningovascular neurosyphilis by this method, giving a daily dose of 500,000 units of penicillin intramuscularly for 14 days, and agree that the immediate clinical response is good. It is far too early,

\*The opening paper read at a joint discussion between La Société de Neurologie de Paris and the Section of Neurology, Royal Society of Medicine, on April 15, 1947.

however, to judge the ultimate results; should these prove satisfactory when cases have been followed up for sufficiently long periods, the problem of treating cases of chronic neurosyphilis in out-patient departments, instead of admitting them to hospital as at present, would largely be solved. If it is eventually shown that a continuous and fairly constant level of penicillin in the blood is really necessary for full therapeutic effects, the preparations of penicillin in oil and beeswax may prove valuable—for example, injectio penicillin. oleosa, B.P.

I have invariably used sodium penicillin in watery solution for injection by all routes and have no personal experience of oil-wax preparations. Harrison (1946), who has been using these preparations, states that after a deep subcutaneous injection of 300,000 units in oil-wax, penicillin can be found in the blood serum for 12 to 16 hours but not at the end of 24 hours. Similarly, Kirby, Leifer, and their co-workers (1946) found that an injection of 300,000 units of highly purified calcium penicillin (of potency 1,000 units per mg. in 1 ml. of peanut oil with 4.8% of beeswax) given by subcutaneous injection maintains an assayable blood level of penicillin for 20 hours. Thus patients can be treated with one injection daily of 300,000 units in oil-wax for 10 to 14 days (total dosage of 3,000,000 to 4,200,000 units). From these observations it would appear that, if the maintenance of a fairly constant concentration of penicillin in the blood throughout the period of treatment proves to be necessary, the use of oil-wax preparations is the method of choice for daily injection in out-patient cases of neurosyphilis. If such a continuous level in the blood should not be necessary, however, then watery or saline solutions of penicillin are preferable, for I am aware that examples of persistence of the oily preparation in the tissues (non-absorption) have been reported, and occasionally a localized and tender induration appears three days after injection of the oil-wax penicillin (Pillsbury, 1945).

#### Penicillin Combined with Arsenicals and Bismuth

In view of the percentage of relapses reported in cases even of early syphilis treated with penicillin alone, and in spite of the initial beneficial effects following penicillin treatment, I have at no time abandoned the use of arsenicals and bismuth—in conjunction with penicillin—in treating cases of neurosyphilis. It is of interest to note that many authors (e.g., Marshall, 1946; McElligott, 1946; Olansky and Chinn, 1946) advocate the combined use of penicillin, arsenicals, and bismuth not only in neurosyphilis but also in early syphilis. It is even possible that a synergistic action exists between the two types of treatment as indicated by the animal experiments of Eagle and his co-workers (1946) and the observations of Levaditi and Vaisman (1946).

Using the standard course of penicillin administered parenterally, the most appropriate method of applying the combined treatment is to give three injections of arsenic and bismuth during the week of penicillin treatment in order to utilize the possible synergistic action (in doses of 0.3 g. of neoarsphenamine and 0.2 g. of bismuth). The course of penicillin is then followed up by 12 injections of an arsenical—0.45 g. of neoarsphenamine or 0.06 g. of "mapharsen" ("mapharside")—and bismuth (0.2 g.) at weekly intervals. Some observers prefer to give the arsenical and bismuth every four days for forty days—10 injections of each substance—using 0.45 g. of neoarsphenamine, 0.06 g. of mapharsen, or 0.09 g. of "neohalarsen," given intravenously, and 0.2 g. of bismuth intramuscularly (McElligott, 1946).

It will not be possible fully to assess the final results of penicillin treatment—even when combined with the older methods—for several years. A careful and prolonged

follow-up of cases is imperative. We can only wait and ascertain what proportion of the thousands of cases of early syphilis treated with penicillin alone in the British and U.S. Forces will eventually relapse or develop some form of neurosyphilis. Consequently, as a result of further observations, it may be necessary to amplify, extend, or otherwise alter the schemes of treatment at present in use.

#### Intrathecal Administration of Penicillin

However advisable in acute meningeal infections such as streptococcal and pneumococcal meningitis, is the intrathecal injection of penicillin either indicated or advisable in neurosyphilis—or can equally good therapeutic results be obtained by parenteral injection alone?

The evidence as to whether penicillin given by parenteral injection is able to penetrate the blood-brain barrier (choroid plexus) into the subarachnoid space has been somewhat contradictory. Thus it is stated that penicillin injected parenterally in standard doses does not reach the cerebrospinal fluid in demonstrable quantities (Marshall, 1946). McDermott and Nelson (1945) found only traces of penicillin in the cerebrospinal fluid after the intramuscular injection of a single dose of 300,000 units or over (which produced a blood concentration of penicillin of 10 units or more per ml.). On the other hand, Schwemlein and his co-workers (1946) claim that penicillin injected parenterally reaches the cerebrospinal fluid in adequate amounts. There is more recent evidence that massive single doses of penicillin—for example, 600,000 units given every hour—may penetrate the blood-brain barrier in larger quantities (Lourie *et al.*, 1945; Lloyd-Jones, Allen, and Donaldson, 1946; Schwemlein *et al.*, 1946).

It is considered by some observers (e.g., Rosenberg and Sylvester, 1944; Dickson Wright, 1946) that if the choroid plexus is damaged by inflammation—for instance, in meningitis—penicillin may reach the cerebrospinal fluid in somewhat larger quantities than normally.

Is it necessary for penicillin to pass the blood-brain barrier in order to exert an adequate therapeutic effect in neurosyphilis (including parenchymatous neurosyphilis)? My answer is "No," since adequate clinical response, with rapid reduction in cell and protein content of the cerebrospinal fluid towards normal, is obtainable in most, if not all, cases of meningovascular neurosyphilis treated by parenteral injections of penicillin; and, further, in forms of parenchymatous neurosyphilis (general paresis and tabes dorsalis) considerable improvement in the pathological cell content and total protein of the cerebrospinal fluid is observed in many cases—as well as a slower decrease in the intensity of the serological reactions. Consequently, whether or not penicillin passes the blood-brain barrier in "adequate" amounts, it is certainly capable of exerting considerable effect on the meninges and central nervous system when given by parenteral injection. In view of these facts it is probable that the reaction between the infecting organism and the antibiotic takes place mainly in the leptomeninges, these membranes being well supplied with blood vessels. In my earlier cases of neurosyphilis treated with penicillin I used the intrathecal route, giving 10,000 units in 10 ml. of normal saline by lumbar puncture every day for eight to ten days, at the same time administering the usual standard penicillin treatment by intramuscular injection (40,000 units every three hours for seven and a half to eight days). I was fortunate in meeting with no excessively severe reactions—as judged by certain published reports, to which I will refer later—but there is often a brisk meningeal reaction accompanied by some pyrexia and generalized pain after the first intrathecal injection. The cerebrospinal fluid drawn off by lumbar puncture on

the following day will be found to contain a larger number of cells (varying from 500 to 10,000 per c.mm. and including a high percentage of polymorphs) and an increased total protein of from 80 to 250 mg. per 100 ml. The pleocytosis persists, but with diminishing intensity, throughout the course of intrathecal penicillin. In *tabes dorsalis* the initial intrathecal injections may provoke a severe attack of "lightning pains."

As a result of further observation and experience with parenteral injections I have now abandoned routine intrathecal injection of penicillin in neurosyphilis, preferring intramuscular injection in adequate dosage, except for certain cases of *tabes dorsalis* with severe and frequent "lightning pains."

If intrathecal injection is decided upon it is best to give 10,000 units of penicillin in 10 ml. of saline daily by lumbar puncture, more than this quantity of cerebrospinal fluid having been drawn off, and to repeat the injection for seven to ten days. (In acute streptococcal and pneumococcal meningitis intrathecal penicillin may be necessary at intervals of 12 hours for the first three or four days.) It has been shown (Cairns *et al.*, 1944) that a single intrathecal dose of 4,000 units maintains an adequate level of penicillin in the cerebrospinal fluid for 24 hours. Penicillin appears in the lumbar cerebrospinal fluid after an intraventricular injection, and administration by lumbar puncture gives rise to a substantial concentration in the cerebrospinal fluid bathing the brain and even in the ventricular fluid. Cooke and Goldring (1945), however, advance the view that the presence of large amounts of penicillin in the cerebrospinal fluid after lumbar intrathecal injection suggests stasis to be the reason for such high concentration, whereas the presence of large amounts of penicillin in the intraventricular fluid suggests that the blood stream may be the source of the penicillin, as the direction of the flow of the cerebrospinal fluid is from the ventricles to the subarachnoid space.

The introduction of penicillin by cisternal puncture in neurosyphilis seems to be not only inadvisable but hazardous according to the results of Neymann, Heilbrunn, and Youmans (1945). These authors report muscular twitchings and generalized convulsions in cases of general paresis, as well as two deaths from what they term "chronic penicillin encephalopathy" following the injection of penicillin by the cisternal route. Lesions of the cauda equina following the injection of penicillin by lumbar puncture have been described, and convulsions have resulted from intraventricular injections (Smith, Duthie, and Cairns, 1946). Also, the American *Year Book of Neurology and Psychiatry*, 1946, refers to motor weakness, optic atrophy, bladder incontinence, neuroradiculitis, mental abnormalities, and cerebral atrophy occurring after the intrathecal and intraventricular administration of penicillin (Siegal, 1945; Walker and Johnson, 1945; Sweet, Stanley, *et al.*, 1945). Some of these effects may have been due to impurities in the penicillin used, as earlier preparations of penicillin issued were considerably less pure than those now available.

#### Therapeutic Reactions

All observers testify to the relative harmlessness of penicillin compared with its unexampled destructive effect on many bacteria. By rapid intravenous injection the penicillin concentration of the blood can be forced up to a level 1,000 times greater than is necessary to produce therapeutic effects without untoward incident (Fleming, Young, Suchet, and Rowe, 1944). Even in early syphilis, however, some 50% of cases treated with penicillin experience varying degrees of malaise and usually slight pyrexia after the initial doses (McElligott, 1946). A few individuals may be sensitive to some constituent of the

penicillin. Generalized urticaria, with or without constitutional disturbance, has occasionally been observed one week or so after the first injection, but it is not an indication for discontinuing treatment (Pillsbury, 1945). Only very few instances of more severe systemic reactions, including profound malaise, continued pyrexia, and toxicodermal reactions, have been reported (Kolodny and Denhoff, 1946). There is no recorded instance of any damaging effect on bone marrow, liver, or other organs. With the more recent, and purer, preparations of penicillin such reactions are less frequent; consequently, the earlier reactions recorded were probably due to impurities. Calcium penicillin is said to be six times more toxic than sodium penicillin, but even this is negligible, as the lethal dose in a man weighing 60 kg. would seem to be over 10,000,000 units (Welch, Chandler, Davis, and Price, 1945).

Herxheimer-Jarisch reactions have been reported from time to time in cases of neurosyphilis in addition to other forms of late syphilis, as well as in early syphilis, treated by penicillin alone. Personally, I have observed no more than a pyrexial reaction following the first or second dose of penicillin (given intramuscularly), and very occasionally some discomfort in the legs with temporarily increased spasticity in cases of meningo-myelitis. To judge from some of the published reports, however, it would seem that I have been fortunate, as various forms of exacerbation of symptoms, including thrombosis, have been observed, and even acute transverse myelitis (McElligott, 1946). In view of the possibility of Herxheimer-Jarisch reactions following penicillin injection, however, I now prefer to give six injections of bismuth (0.5 ml. of "bismostab") every four days in meningo-vascular neurosyphilis, and four injections of bismuth at the same intervals in parenchymatous neurosyphilis, before proceeding with the full course of penicillin.

#### Meningovascular Neurosyphilis

There is abundant evidence that penicillin—in adequate dosage and administered by whatever route—has a striking initial beneficial effect on all forms of meningovascular neurosyphilis, especially acute forms. The therapeutic effect is observed not only in the tendency to subsidence of clinical symptoms but more particularly in the rapid improvement in pathological cerebrospinal fluids. The pleocytosis and the increased protein content will often show a noteworthy decrease within a few days of starting treatment and reach a normal level within two to four weeks. The intensity of the Wassermann reaction (and other serological reactions) in the cerebrospinal fluid gradually decreases and may become negative within two to four months. These results suggest an actual selective action of penicillin on pathological cerebrospinal fluids or meninges, as there is no parallel decrease in the serological reactions of the blood. The blood Wassermann reaction may continue positive for many months, and even indefinitely, after treatment limited to penicillin.

The clinical response of syphilitic meningitis to penicillin (by parenteral injection) is usually immediate and dramatic. In acute forms of the disorder headache and neck rigidity may disappear within 48 to 56 hours, and the increased cell and total protein content of the cerebrospinal fluid rapidly reaches a normal level. The serological response, as stated previously, is somewhat slower. Cranial nerve palsies improve gradually and usually recover. Nelson and Duncan (1944) mention five cases of syphilitic meningitis with cranial nerve palsies, all of which made a good recovery with penicillin treatment, the cranial nerve lesions disappearing completely in four cases. In the remaining case some residual weakness was still present after 98 days.

From the observations of Stokes and his co-workers (1944 to 1946) it is doubtful if any further change towards improvement occurs after four months from the termination of penicillin treatment. Consequently these authors have thought it advisable to repeat the course of penicillin after this four-month interval. At the time of reporting, however, they had noted no conspicuous benefit as a result of repeating the course. Repetition is advocated by other observers. For example, two courses of penicillin of a total dosage of 2,400,000 units at a week's interval (Marshall, 1946) and the usual course of penicillin at intervals of three weeks for two or more courses (McElligott, 1946). Further time must elapse before the value of such repeated courses can be finally assessed.

As stated previously, in most cases of neurosyphilis (especially parenchymatous forms) the serological reactions in the blood—particularly the Wassermann reaction—are little affected by penicillin treatment and will often continue to show positive results long after the cerebrospinal fluid has become normal. This observation may furnish a further argument for following up the course of penicillin with arsenical-bismuth therapy; also relapse may occur in a cerebrospinal fluid that has become normal as a result of penicillin treatment although a return to the original pre-treatment severity is unusual.

### Parenchymatous Neurosyphilis

Even in parenchymatous forms of neurosyphilis, such as general paresis (G.P.I.), the initial effect of penicillin treatment—injected by whatever route—on the symptomatology (usually) and upon the cerebrospinal fluid changes is remarkably good. In cases of early general paresis treated with penicillin alone I have seen the cell and protein content of the cerebrospinal fluid become normal within four weeks, and even a strongly positive Wassermann reaction becomes negative within two months; the blood Wassermann reaction continued strongly positive. Six months later, however, the Wassermann reaction in the cerebrospinal fluid may be found weakly positive, the blood Wassermann reaction still remaining strongly positive. These later results determined me to combine penicillin treatment with the usual course of fever therapy—for example, malaria, 10–12 rigors—in all cases of general paresis; and in *tabes dorsalis* to follow up the penicillin treatment with full arsenical and bismuth therapy.

#### (a) General Paresis

Some authors claim definite clinical improvement in cases of general paresis treated by penicillin alone. As judged by the literature, however, most observers now use penicillin in combination with either the usual arsenicals, "tryparsamide," bismuth, or some form of pyrexial therapy for the treatment of this condition. The results reported are somewhat conflicting. All observers agree, however, that even when penicillin alone is used some improvement occurs in the pathological state of the cerebrospinal fluid in fully 60% of cases. This improvement is not sufficient to guarantee permanent benefit (confirmed by my own experiences); also, it has to be remembered that similar improvement in the cerebrospinal fluid in cases of general paresis may result from initial treatment with arsenical preparations, only to be followed by relapse at a later stage. So far as I am aware no case of general paresis has been reported to have become serologically negative in both cerebrospinal fluid and blood, with the maintenance of clinical improvement, on penicillin treatment alone. The best results appear to have been obtained in those cases treated with penicillin in combination with some form of pyrexial therapy (Goldman, 1945). Some clinicians have used a total dosage of 3,000,000 units of penicillin in conjunction with only "half the usual amount of fever therapy." Rose and his co-workers (1946), for instance, report 49 cases of general

paresis receiving this form of treatment: 25 improved, 21 showed no change, and 3 became worse.

In cases of general paresis treated with full malarial or fever therapy, whether or not followed by courses of arsenical and bismuth injections, the positive serological reactions in blood and cerebrospinal fluid take two to four years to become negative. The addition of an initial course of penicillin to therapeutic malaria certainly appears to hasten the reversal of the positive serological reactions, especially in the cerebrospinal fluid.

From my personal experiences the scheme I would advocate for the treatment of general paresis is as follows:

After four initial injections of bismuth—for example, bismotab 0.5 ml., or metallic bismuth 0.2 g.—to obviate Herxheimer-Jarisch reactions, a full course of intramuscular penicillin is given in doses of 40,000 units every three hours (preferably), or 300,000 units every 12 hours, for a total dosage of 4,000,000 or even 5,000,000 units. This is then followed by the usual standard course of fever therapy—e.g., induced malaria to 12 rigors (if possible, or at least 10). Arsenic and bismuth therapy is then given in weekly doses of neoarsphenamine (0.45 g.) or mapharsen (0.06 g.) or "acetylarsan" (diethylamine acetarsone) (3 ml.) and bismuth—e.g., 1 to 0.5 ml. of bismotab=20% suspension of precipitated metallic bismuth in isotonic glucose solution. Twelve injections of each substance constitute a course. Three such courses should be attempted during the year, the intervals between them depending upon the patient's tolerance and progress. The cerebrospinal fluid is examined every six months and treatment is continued until the serological reactions become negative. A further examination should be made six months later and then at intervals of one year for two years.

In cases of general paresis in which malarial or fever therapy is contraindicated by reason of hyperpiesis or cardiovascular disease one needs to rely on penicillin alone. So far I have had only two such cases, which I have been able to follow up for an appreciable period.

One case, that of a woman aged 47 with early general paresis showing the usual and typical cerebrospinal fluid changes (14 small lymphocytes, total protein 60 mg., Lange curve of parietic type, strongly positive Wassermann reaction, and Mciniec 4431), had aortic valvular disease with regurgitation and a blood pressure of 250/100. She was given 10,000 units of penicillin intrathecally in 10 ml. of saline daily for nine days, and at the same time the standard course of 40,000 units of penicillin every three hours for 7½ days, by parenteral injection. No noteworthy therapeutic reaction occurred, and meningeal reaction following the first intrathecal injection was comparatively slight (cerebrospinal fluid 420 cells—60% polymorphs and 40% lymphocytes—and total protein 100 mg.). Two months later the cerebrospinal fluid showed only two cells, total protein 25 mg., Wassermann reaction negative, and Lange curve still parietic. The blood Wassermann reaction was still strongly positive. Six months later her clinical condition remained satisfactory and the cells and total protein of the cerebrospinal fluid were normal; the Wassermann reaction of the cerebrospinal fluid, however, was now weakly positive and that of the blood still strongly positive.

The second case was that of a man aged 45 with early general paresis, hyperpiesis—blood pressure 240/120—and enlarged left ventricle. The cerebrospinal fluid changes were typical, with strongly positive Wassermann reaction and parietic Lange curve. The usual standard course of penicillin by intramuscular injection was given. He received no intrathecal treatment. Three months after treatment the cell and total protein content in the cerebrospinal fluid were normal and the Wassermann reaction was negative; the Lange curve was still parietic and the blood Wassermann reaction positive. Six months later, (nine months after penicillin treatment) his clinical condition had remained more or less stationary, but the cerebrospinal fluid Wassermann reaction was positive, as was that of the blood; the Lange curve was still parietic in type.

The persistence of the parietic Lange curve in both cases is of interest. With the tendency to serological relapse in these cases, it would seem inadvisable to rely on penicillin alone in the treatment of general paresis if malarial or fever therapy is likely to be tolerated. To detect any tendency to relapse the cerebrospinal fluid should be examined at intervals of six months until the serological reactions have been negative for two years, clinical improvement having been maintained. Taboparesis is treated in the same manner as general paresis.

#### (b) Tabes Dorsalis

No dramatic change is to be expected in *tabes dorsalis* following penicillin treatment, although in common with other forms of neurosyphilis a pathological cerebrospinal fluid usually shows definite improvement, and there is a

improvement in symptoms—even if temporary—in some 40% of cases.

As a result of earlier experiences I have not been in favour of treating *tabes dorsalis* with malarial or fever therapy; this I have stated elsewhere (Worster-Drought, 1940). After two or three years' intensive treatment with courses of arsenical and bismuth therapy most cases of *tabes dorsalis* (and especially early cases) can be arrested and the serological reactions rendered negative. Admittedly, a negative serology does not necessarily indicate arrest of the disease process, and some symptoms—more particularly attacks of lightning pains—are apt to persist.

I now treat cases of *tabes dorsalis* with an initial course of penicillin given intramuscularly. Although all the earlier cases received the usual standard course I have treated later cases with a larger total dosage (40,000 units every three hours, up to a total of 4,000,000 or 5,000,000 units); other cases have received larger doses at longer intervals (300,000 units every 12 hours or 500,000 units every 24 hours, for eight days). The course of penicillin is then followed up with arsenical (neoarsphenamine or acetylarsan) and bismuth therapy in the usual doses. I intend to continue this arsenical-bismuth treatment up to one or two years, according to the progress of the patient's symptomatology and serological reactions, which are determined from time to time at the same intervals as given for general paresis.

Attacks of so-called lightning pains often persist in *tabes dorsalis* even when other symptoms are absent and when the disease is apparently arrested, or at least has reached a quiescent stage, and long after the serological reactions have become negative and the cerebrospinal fluid is normal. I have now treated several cases showing negative serological reactions with courses of penicillin by intrathecal and intramuscular injection combined and by intramuscular injection alone. The results as regards the lightning pains have been variable. In a few cases treated by intramuscular injections only (the usual standard course), relief from lightning pains has occurred without relapse over periods of observation up to 12 months. In other cases a remission of several months' freedom from these pains has followed the course of treatment—that is, considerably longer intervals between the attacks of pain than before treatment—while other cases have remained unaffected.

I have also treated a few cases (*tabes dorsalis* with negative serology and apparent quiescence of the disease apart from the lightning pains) with penicillin given intrathecally (10,000 units in 10 ml. of saline daily for eight days and accompanied by the usual standard course of penicillin injections intramuscularly), and the results as regards subsequent freedom from lightning pains (up to six months' follow-up observation) have been rather better than in those cases treated by parenteral injection alone. The disadvantage of intrathecal treatment, apart from the usual risks, in these cases, however, is that the first intrathecal injection of penicillin is apt to provoke a very severe attack of generalized nerve-root pain accompanied by pyrexia and considerable meningeal reaction.

Some cases of gastric crises have been definitely improved by penicillin treatment, but a few have remained unaffected. I have not observed any material change in Charcot's arthropathy as a result of penicillin treatment.

#### (c) Primary Optic Atrophy

I have been able to convince myself that malarial therapy (preferably followed by bismuth and arsenical treatment) is capable of arresting primary optic atrophy of syphilitic origin (*tabes optica*) from a series of cases followed up to six years after treatment. It is known that 75% of untreated cases become totally blind within three years and 100% within five years (Lehrfeld and Gross, 1938). Consequently the observation of any patient treated must extend to five years or longer before success can be claimed.

The experiences of Moore, Woods, Hopkins, and Sloan in America, ranging from 1932 to 1942, also confirm the beneficial effects of malarial therapy in primary optic atrophy. Only 14.6% of 16 cases of primary syphilitic optic atrophy became blind within three years of treatment, and thereafter there was no rise in the incidence of blindness.

"Excellent initial effects" following penicillin treatment are reported by some observers. Rose and his co-workers (1946) record "apparent arrest of visual loss" in five of six cases of primary optic atrophy treated with penicillin and half the usual amount of fever therapy. In view of the fact, mentioned above, that primary optic atrophy can slowly progress for five years before blindness ensues, it is clearly far too early to consider possible arrest of primary optic atrophy following penicillin treatment alone, and I doubt if complete arrest is possible as a result of penicillin treatment, however administered, without concomitant fever therapy.

I would still advocate full malarial or fever therapy in primary optic atrophy, but I now start treatment with a course of intramuscular penicillin (total dosage of 4,000,000 units) and follow this with 10 to 12 malarial rigors, according to the patient's tolerance. Also, I prefer to follow the malaria with arsenical and bismuth therapy until the serological reactions become negative.

#### (d) Late Asymptomatic Neurosyphilis

Asymptomatic neurosyphilis is a term applied to the condition in which pathological changes due to syphilitic infection exist in the cerebrospinal fluid but the patient neither complains of symptoms nor shows any abnormal neurological signs.

Two types of asymptomatic neurosyphilis must be distinguished: (1) That occurring in the earlier stage of syphilitic infection coincident with or shortly after the secondary stage or period of general invasion (early asymptomatic neurosyphilis). This form of the disorder is of meningo-vascular type and readily amenable to treatment. (2) That detected long after primary infection as a result of an examination of the cerebrospinal fluid either because the blood has been found to yield a positive Wassermann reaction—for example, in a proposed blood donor—or during the routine investigation of a patient with a history of syphilis (late asymptomatic neurosyphilis). It is probable that this latter type is classifiable as a form of parenchymatous neurosyphilis in that the pathological changes in the cerebrospinal fluid are only slightly, if at all, influenced by intensive treatment with the ordinary antisyphilitic remedies. Observations have shown that late asymptomatic neurosyphilis often terminates in general paresis—a fact that led Solomon to term the condition "paresis sine paresi." Even with malarial or fever therapy followed by arsenical-bismuth treatment three or four years may elapse before the serological reactions in the blood and cerebrospinal fluid are favourably influenced.

From the reports on penicillin treatment applied to asymptomatic neurosyphilis it is clear that not sufficient distinction has been drawn between the "early" and the "late" type. As a form of meningo-vascular neurosyphilis early asymptomatic neurosyphilis is rapidly and favourably influenced by penicillin. Also, so far as can be judged at so early a stage, penicillin is most valuable in the treatment of late asymptomatic neurosyphilis even if regarded only as an additional measure. Reports indicate improvement in the cerebrospinal fluid of many cases treated with penicillin alone, although in some of the records it is by no means clear whether the authors are including cases of early asymptomatic neurosyphilis. Stokes and his co-workers (1946) report improvement in 60% of cases of asymptomatic neurosyphilis; also Lloyd-Jones and his co-workers (1946) report that of 10 cases treated with massive daily doses of penicillin (300,000 to 500,000 units) given intramuscularly to a total dosage of 2,400,000 to 5,000,000 units, the cerebrospinal fluids of four of the 10 cases reverted to normal within six weeks (these cases may have been examples of early asymptomatic neurosyphilis). Although the cerebrospinal fluids of the remaining six cases showed improvement (as one would expect) they had not become serologically negative at the time of reporting.

Owing to the known severity of late asymptomatic neurosyphilis as regards prognosis, my view is that the condition should be treated with a full course of penicillin consisting of a total dosage of at least 4,000,000 units given by intramuscular injection in doses of 40,000 units every three hours (preferably), of 300,000 units every 12 hours, or of 500,000 units every 24 hours; with the last-mentioned method the total dosage should

be 5,000,000 units. The period of penicillin therapy is then followed by full pyrexial therapy—for example, malaria, 10 to 12 rigors—and, finally, by the usual arsenical-bismuth therapy until the cerebrospinal fluid is normal and the serological reactions are negative. As with other cases of neurosyphilis, the cerebrospinal fluid should be examined at intervals of six months, and, following a negative result, at yearly intervals for two years.

#### (c) Erb's Syphilitic Spinal Paralysis

This form of parenchymatous neurosyphilis (antero-lateral spinal sclerosis of syphilitic origin) results from degeneration in the antero-lateral portions of the spinal cord, and is notoriously resistant to treatment by all previously known methods. Tucker (1946) has treated four cases with penicillin, giving a total dosage of 2,000,000 to 10,000,000 units by intramuscular injection in repeated doses of 25,000 units every three hours for 10 to 25 days. No improvement resulted. One patient died, six months after treatment, from *Clostridium welchii* infection, and the other three failed to show improvement after 121, 376, and 582 days. In the only case I have been able to treat with penicillin the result was similar.

#### Summary and Conclusions

Penicillin has a definite and established place in the treatment of neurosyphilis.

Most of the present-day experiences are based on the "standard" course of penicillin established in 1944 for the treatment of early syphilis in the British Services and in the U.S. Army in Europe (a total dosage of 2,400,000 international units given by parenteral injection in doses of 40,000 units every three hours, day and night, for seven and a half days).

In view of the percentage of relapses even in early syphilis it is considered doubtful if this course is sufficient for neurosyphilis. It is suggested that a total dosage of at least 3,000,000 units be given to all cases of neurosyphilis and that in parenchymatous neurosyphilis the total dosage should reach 4,000,000 to 5,000,000 units.

It may prove unnecessary to keep penicillin in the blood at as high a continuous level as possible throughout the period of treatment. If so, equally good therapeutic effects may be obtainable with larger doses of penicillin given at longer intervals (300,000 units given every 12 hours or 500,000 units every 24 hours for 8 to 15 days). Such a method would enable cases of chronic neurosyphilis to be treated as out-patients.

Intramuscular injection is the best method of administering penicillin. For reasons given, the intravenous route—either by continuous drip or by repeated single injections—has little to commend it.

There is no evidence that the intrathecal administration of penicillin is of greater therapeutic value in neurosyphilis than when the remedy is given by intramuscular injection. Because of the resulting reactions and the various additional risks intrathecal injection of penicillin is best avoided in most cases of neurosyphilis.

Owing to the risk of possible Herxheimer-Jarisch reactions following the first doses of penicillin, all cases of neurosyphilis should receive an initial series of bismuth injections before starting the full course of penicillin.

The rapid beneficial effects of penicillin on the cell and protein content of the cerebrospinal fluid suggest a special selective action on the meninges or cerebrospinal fluid.

In meningovascular neurosyphilis the course of penicillin should be followed by full arsenical and bismuth therapy in view of the percentage of relapses, even in cases of early syphilis treated with penicillin alone.

General paresis is best treated with an initial course of penicillin of total dosage of 4,000,000 to 5,000,000 units followed by full malarial or fever therapy (10 to 12 malarial rigors). Finally, the usual courses of arsenic and bismuth are advisable until the serological reactions become negative.

In cases of general paresis (and taboparesis) in which malarial or fever therapy is contraindicated by reason of cardiovascular

disease, one must rely on penicillin alone. Some improvement, but not cure, can be expected.

In tabes dorsalis no dramatic change follows penicillin treatment. Cases are best treated with an initial course of penicillin and then with the usual courses of arsenicals and bismuth for two to four years until apparently quiescent and the serological reactions have become negative. Special symptoms such as lightning pains and gastric crises benefit from penicillin in some cases, including those in which the serological reactions are already negative.

Primary optic atrophy of syphilitic origin can be arrested in a fair proportion of cases by malarial therapy. Penicillin alone is not likely to arrest the optic atrophy, but may prove useful in hastening arrest or in bringing about arrest in an even larger proportion of cases. Treatment should consist of an initial course of penicillin of total dosage 4,000,000 to 5,000,000 units, followed by full malarial therapy (10 to 12 rigors) and afterwards arsenicals and bismuth. Observation of any patient must extend to five years or longer before success can be claimed for any form of treatment.

A distinction must be drawn between early asymptomatic neurosyphilis and late asymptomatic neurosyphilis. The latter condition, being of serious import, must be treated with penicillin and malarial or fever therapy on the same lines as general paresis.

At least five years must elapse before we can determine fully the value of penicillin in neurosyphilis.

## THE MODERN TREATMENT OF NEUROSYPHILIS

BY

F. GRAHAM LESCHER, M.C., M.D., F.R.C.P.

Physician, Derbyshire Royal Infirmary

AND

H. R. M. RICHARDS, M.B., B.Ch.

Medical Officer in charge of Venereal Disease Clinic,  
Derbyshire Royal Infirmary

During the last eight years over 50 patients suffering from various types of neurosyphilis, chiefly in the earlier stages, have been treated in this clinic by three different methods. Twenty-five who had not responded satisfactorily to pentavalent arsenic and bismuth were treated by infection with tertian malaria, followed by chemotherapy (Lescher and Richards, 1944). Ten more were given penicillin alone; and a further 19 were treated by malaria combined with penicillin. Forty-seven have been followed up both clinically and serologically, examinations of the spinal fluids having been made at definite intervals. It is our intention here to try to compare the results of these three different methods of treatment.

### Treatment of Neurosyphilis with Malaria and Chemotherapy

Until recently it was considered that the most satisfactory method of treatment of neurosyphilis was with malaria, followed by tryparsamide and bismuth. The latest review by Nicol (1946), who treated and followed up 217 patients suffering from taboparesis or dementia paralytica. Over 50% improved clinically, and in 70% the spinal fluids became negative. Of the 25 patients in our series who were treated by this method, 20 have been followed up for from five to eight years (Tables I and II).

TABLE I.—Clinical Results after Treatment with Malaria and Chemotherapy

Type	No.	Much Improved	Improved	Stationary	Worse
Meningovascular	5	4	1	—	—
Tabes	10	2	4	—	—
Tabes with marked optic atrophy	4	—	—	2	2
Dementia paralytica	1	—	1	—	—
Totals	20	6	6	4	4

TABLE II.—Serological Results after Treatment with Malaria and Chemotherapy

Type	No.	Cerebrospinal Fluid				Blood		
		Strong Pos.	Weak Pos.	In-active	Neg.	Neg.	Im-proved	Pos.
Meningovascular	5	—	—	2	3	3	2	—
Tabes	10	1	2	1	6	6	2	2
Tabes with marked optic atrophy	4	—	—	3	1	1	1	—
Dementia paralytica	1	—	—	1	—	—	1	—
Totals	20	1	2	7	10	10	6	4

In classifying the spinal fluids in neurosyphilis Dattner's method (Dattner *et al.*, 1944) has been adopted. The various groups may, however, merge one into another.

(1) *Strongly Positive*.—Cell count and total protein increased. Paretic gold curve (first zone). Strongly positive W.R.

(2) *Weak Positive*.—Cell count normal or slightly raised; amount of protein increased. Paretic gold curve. W.R. strongly positive to positive.

(3) *Inactive Fluid*.—Cell count normal; marked reduction in the total protein. Gold curve may or may not be positive. W.R. positive.

(4) *Negative Fluid*.—Cell count normal; normal amount of protein. Normal gold curve. Negative W.R.

Each patient in the series was infected with tertian malaria, and ten bouts of fever were generally allowed. The duration of each bout averaged from eight to twelve hours, and no difficulty was experienced in stopping the infection by means of quinine. During the stage of fever the intake of fluids and the output of urine must be watched, and the urine should be tested for its salt content, as there is a danger of salt depletion. No complication occurred. Care was taken, however, not to employ malarial therapy in any patient of poor nutrition, or in those suffering from debilitating diseases or infections, especially those of the kidneys and bladder. Further, malarial therapy was not given to those in whom there was evidence of damage to the cardiovascular, renal, or hepatic system.

To assess accurately the clinical results in a chronic disease so complex as neurosyphilis is far from easy, for clinical improvement depends not only on the death of the spirochaete and the subsidence of the inflammatory reaction but also on the extent of destruction of nerve tissue. It cannot be expected, then, that scarred and destroyed nervous tissue can ever be restored to normal by treatment, or that nervous wrecks can be rehabilitated. The results of treatment in the present series (Table I) conforms in most respects to the results obtained by others. There is often improvement in the general health, as well as in such symptoms and signs as lightning pains, ataxia, and disorders of micturition, and in libido. In some, arrest of failing vision was noted.

However, the clinical disappointments are to some extent offset by the almost mathematical accuracy of the information on the activity of the disease and the need for further treatment gained by serial examinations of the spinal fluid. For in neurosyphilis there is a definite relationship between the pathological state of the nervous system and its reflection in the spinal fluid. Dattner *et al.* (1944) say that "for evaluating the success of treatment in neurosyphilis the spinal fluid syndrome is a far better guide than clinical symptoms." Whelan (1946), after examining a series of patients suffering from dementia paralytica and taboparesis, found that the majority of spinal fluids became inactive within six to twelve months after the termination of treatment with malaria, and, further, that there was a strong probability that the reactions would become negative in from one to three years without any further treatment. She found also that these fluids seldom reverted. Our experience, on the whole, bears out these conclusions.

### Treatment of Neurosyphilis with Penicillin

Although penicillin is being used alone or combined with malaria in the treatment of neurosyphilis in many clinics in this country, few detailed accounts have as yet appeared in the medical press; a number of communications have, however, come from the United States. The earliest was from Stokes and his fellow workers (1944), but as it was a preliminary report no definite conclusion could be reached except that of encouragement. Later the same authors (Stokes *et al.*, 1946) claimed successful clinical and serological results from treatment with penicillin in 197 patients suffering from various forms of neurosyphilis. They found that the maximum improvement occurred in the first 120 days after its use, although it could continue beyond this time. Relapses were infrequent; little difference was found between high dosage (5–8 mega units) and low (1–4 mega units); no better results were obtained from a repetition

of the course. Gammon and his associates (1945), Nelson and Duncan (1945), Rose (1945), and Smith (1947) also reported successful results. O'Leary, Brunsting, and Ockuly (1946) and Mohr and Moore (1946) observed great serological improvement after the use of penicillin, but clinically the results were not so striking. No significant advantage was found to occur with amounts greater than 5 mega units. Marshall (1946) gives two courses of penicillin, followed by chemotherapy, with clinical improvement. Callaway and his associates (1946) consider that treatment with penicillin is more effective than with malaria. On the other hand, Rose and his colleagues (1945) concluded that there was little to choose between malarial therapy followed by trypanamide and that of penicillin alone. Bruetsch (1946) found that penicillin is not so efficacious as malaria in the treatment of syphilitic optic atrophy.

In the above reports a total of 1-10 mega units of penicillin was given in divided doses, intramuscularly, every three hours. The intrathecal route has also been employed. Goldman (1945) considers that the results justify further study, but he gives no account of a follow-up. O'Leary, Brunsting, and Ockuly (1946) and Thrasher (1945) also claim more rapid serological reversals with this method. McDermott and Nelson (1945), Marshall (1946), and Neymann, Heilbrunn, and Youmans (1945), however, consider that this route is dangerous. But as penicillin which contains at least 90% penicillin G (II) and is free from impurities has been issued for special purposes—for example, for intrathecal injection—since these reports, any irritant property that it formerly possessed should be of a lower degree.

Ten patients in our series were treated each with intramuscular injections of penicillin in oil, 125,000 units twice daily, until four mega units had been given. The course was preceded by smaller doses for the first two days to avoid the possibility of a Herxheimer reaction (Tables III and IV). They have been followed up both clinically and

give the answer to this problem; most investigators have certainly stressed this.

### Treatment of Neurosyphilis with Malaria and Penicillin

It is now established that penicillin is a definite spirochaetocidal agent; and malaria has stood the test of time as an effective therapeutic method in the treatment of neurosyphilis, very probably by raising in some manner the immunity of the host, besides having itself a spirochaetocidal action. Eagle and Musselman (1944) have found that the rate at which spirochaetes were killed *in vitro* by penicillin increased with a rise of temperature, the optimum being 39-40° C. It seems reasonable, therefore, to expect that owing to their complementary action a combination of these two methods may be likely to enhance the beneficial effects of either.

A few papers giving preliminary results of this combined treatment have appeared in the United States. However, no reports have yet been published in Great Britain, although the method is being employed in some clinics in this country. Rose and his associates have so treated 70 patients with clinical and, to a greater extent, serological improvement. Reynolds, Mohr, and Moore (1946), and Rose and Solomon (1947) consider that this combined method is superior to that with penicillin alone; Nicoll (1946), despite his success with malaria and trypanamide, advocates treatment with malaria together with penicillin. O'Leary, Brunsting, and Ockuly (1946), however, have found no appreciable difference either clinically or serologically with the combined treatment, compared with that of malaria alone, except in the asymptomatic and meningeal forms of disease.

We started in August, 1945, to use penicillin combined with malarial therapy. Nineteen patients suffering from various forms of neurosyphilis, mostly in the earlier stage, have been so treated and followed up (Tables V and VI); others are at present undergoing this method of treatment, but are not included in this review.

TABLE III.—Clinical Results after Treatment with Penicillin

serologically. There is a difficulty, however, in comparing the results obtained at the present time with penicillin with those obtained with the earlier preparations, for penicillin has been a changing mixture. Formerly much of it contained an appreciable amount of penicillin K, which is inefficacious against *Treponema pallidum*, and this may have been responsible for the poorer results obtained in the treatment of syphilis. At present penicillin of a purity of 90% can be produced, and it does not contain K substance in any significant amount; but to assess accurately the value of penicillin in the treatment of neurosyphilis more knowledge is required, especially as regards the dosage and the duration of treatment. Time and experience should

TABLE V.—Clinical Results after Combined Treatment with Malaria and Penicillin

A wax-oil preparation of penicillin was given just before and during the acute stage of the malarial infection, 250,000 units being injected twice daily, to a total of 4 mega units. To avoid the possibility of a Herxheimer reaction, a small dose was given for the first two days. It was confirmed that penicillin had no inhibiting effect on *Plasmodium vivax*. These patients attended the follow-up department at regular intervals afterwards, and the changes in the spinal fluids were carefully watched. One problem has been practically solved. A patient will not submit willingly

eriodic lumbar punctures if each is followed by a severe headache; but since we have started to use the fine Dattner needle the complaint of post-puncture headache has rarely been made. Follow-up lumbar punctures are performed in the out-patient clinic, and the patient leaves shortly afterwards.

### Comparison of the Three Methods of Treatment

Two difficulties are apparent in attempting a just comparison between these three different methods of treatment. The number of patients in each series is too small to draw an absolute conclusion; and enough time has not elapsed to complete a thorough follow-up of those who have been treated with penicillin or with penicillin combined with malaria. This paper must therefore be considered rather as an interim report.

In comparing the various tables, after reducing the figures to percentages, the best clinical results are seen to have been achieved with malaria and penicillin, closely followed by those obtained with penicillin alone; the results obtained by combined treatment with malaria and chemotherapy come last.

Serologically there are several points to notice. In our series a greater number of positive spinal fluids became inactive within six months after the combined treatment with malaria and penicillin than with the two other methods. So rapidly may this change occur that some fluids have been found to become inactive directly after the termination of this form of treatment. The total number of spinal fluids that have become inactive and negative is higher in those treated with malaria and penicillin and with penicillin alone; but more fluids have become negative and remained negative after malaria and chemotherapy. It is possible, however, that it is merely a question of time, since those patients who have been treated with the latter therapy have been followed up for a longer period; and there is reason to suppose that in time more spinal fluids of these patients treated with malaria and penicillin will eventually become negative. After treatment with malaria and chemotherapy a greater percentage of spinal fluids remain positive than with the two other methods.

It seems, therefore, that in active neurosyphilis the method of choice, at least for the present, is to treat the patient immediately with penicillin and malaria (provided there is no contraindication to the latter). If at the end of twelve months from the termination of this method of treatment the spinal fluid is still found to be positive, or if it remains inactive after two years, treatment with penicillin or with penicillin and malaria can be repeated. Even in "burnt-out" cases of neurosyphilis with subjective sensations and objective signs, but with negative spinal fluids, clinical improvement may still occur with further treatment.

### Treatment of Latent Neurosyphilis

There is enough evidence to show that *Treponema pallidum* may invade the central nervous system early in the septicaemic stage of the disease, yet the organism can remain latent for a varying period without showing clinical evidence. In asymptomatic neurosyphilis, which can easily be detected by the examination of the cerebrospinal fluid, correct therapy is of the greatest importance, for by it further progress can be prevented. Thorough treatment with trivalent arsenic, together with bismuth, will often at an early stage cause a positive fluid to revert permanently to normal. For in dealing with neurosyphilis it is not enough to wait for obvious clinical signs of disease, as by his time irreparable damage has been done. The spinal fluids of all patients who have received adequate treatment

for early syphilis should therefore be examined at the end of the first year of treatment. A positive fluid will mean that there is a danger that the patient may at any time develop clinical neurosyphilis, with pathological changes in the brain or spinal cord. In our opinion intensive treatment, preferably with penicillin and malaria, should under these circumstances then be started.

It is also advisable to employ the latter method of treatment in those who show evidence of latent neurosyphilis of longer standing. If a positive Wassermann reaction in the blood is found in a person with no other signs of syphilis, and who has not had adequate treatment, it will often be observed that the spinal fluid is also positive. (We have seen this a number of times in prospective blood-donor volunteers on whom a blood Wassermann reaction has been performed as a routine.)

### Summary

Forty-nine patients suffering from neurosyphilis in varying forms and degrees have been treated by one of the following three methods: 20 with malaria and chemotherapy, 10 with penicillin, and 19 with malaria together with penicillin.

Each patient has been followed up clinically and serologically. An attempt has been made to compare the results of these three different methods of treatment.

The Communist Party has issued a pamphlet entitled *Health Centres* (3d. post free from Central Books, Ltd., 2-4, Parton Street, London, W.C.1). This memorandum outlines advantages to the general public to be obtained from health centres, as well as those to the medical profession, such as regular hours off duty and periods for postgraduate study. It suggests that the most suitable size for a health centre in an urban area covering a population of 10-20,000 would be for 5-10 doctors. There would be individual consulting rooms, one comfortably furnished waiting room, a large treatment room providing facilities for minor surgery, a rest room, a reception office, and a dispensary. In addition there would need to be W.C.s, store rooms, a kitchen, and accommodation for staff. Such a centre would require 4-8 nurses, 2-4 clerks, 1-2 dispensers, a cook, and several domestics. Ancillary diagnostic and therapeutic aids could be obtained at the nearest hospital, the patient being sent direct from the centre with a request for the desired examination without having to see a specialist at the hospital. In country areas health centres would be smaller, being staffed by perhaps 2-4 doctors. The memorandum contends that "there is an urgent need to get the idea of health centres realized in practice immediately following the inception of the National Health Service," but it recognizes that it will be necessary to improvise in view of the resources available.

## PRIMARY MENINGOCOCCAL OPHTHALMIA

BY

F. N. SHUTTLEWORTH, M.B., Ch.B., D.O.M.S.

Resident Ophthalmic Officer, Leeds General Infirmary

AND

J. G. BENSTEAD, M.A., M.B., B.Chir.

Demonstrator of Bacteriology, University of Leeds

The following two cases, seen in Leeds school-children, are considered worthy of record because the condition is uncommon and was relatively unknown until the recent war, during which several cases have been described. With the exception of the four cases of Hayden and Hayden (1939), Bennett (1940), and Clifton and Laird (1941); all cases in which the literature has been available to us have occurred in America.

## Case I

A boy aged 7 years reported at the ophthalmic casualty clinic with a sore left eye which had troubled him since the previous evening. Examination showed a left acute purulent conjunctivitis; the cornea was hazy, it did not stain, and there was no hypopyon. The right eye was white. Hot steam bathings, mercury oxycyanide lotion 1/8,000, and dark glasses were ordered. On the next day there was no pus but still a marked injection of the conjunctiva. Fluorescein showed a superficial corneal involvement. The following day the boy was admitted with a central corneal ulcer; a swab was taken, and the lacrimal sac syringed and found patent.

Treatment in the ward consisted of thrice-daily hot bathings and application of ung. atropin. 1% twice a day. In seven days the corneal lesion had healed, though there was slight peri-corneal injection, and he was discharged home. Seen as an out-patient three days later, he still had this residual injection, and 30% sulphacetamide drops twice daily were ordered. Six days later the eye was white. No corneal scar remains—evidence that Bowman's membrane was not involved in the ulcerative process of the cornea. Vision in both eyes is 6/6.

**Bacteriology.**—On first isolation a moderately heavy pure culture of *Neisseria* was obtained; the organism grew rapidly and healthily on ordinary chocolate agar without a carbon-dioxide atmosphere. It was strongly oxidase-positive and had the morphological and cultural characteristics of the meningococcus. In view of the possibility that this was a relatively non-pathogenic *neisseria*—such infections having been reported—an interim report was sent, and the organism was subcultured into fermentation-heated blood broth. As the organism fermented glucose and maltose but not sucrose it was considered to be a meningococcus. By the time these fermentation reactions had been checked the eye showed only slight injection.

## Case II

A year later a boy aged 6½ years reported to the out-patient department with a four-day history of a sore and discharging left eye. Examination revealed a chemosis of the left conjunctiva with pus at the inner canthus. There were also two raised nodules on the bulbar conjunctiva, some 2 to 3 mm. in diameter and each discharging pus. The cornea was clear. The right eye was white. A swab was taken and the boy sent home with the eye covered by a flap of lint, and with instructions that hot-spoon bathings should be given three times a day and penicillin drops, 2,000 units per ml., instilled three-hourly. Two days later the eye was much improved; treatment was continued. When seen after a further two days—that is, four days' treatment in all—the eye was white. The local penicillin treatment was continued for another two days. The vision in both eyes is now 6/6.

**Bacteriology.**—A swab was taken at the first attendance. On initial isolation a profuse pure culture of *Neisseria* was obtained. The coccus had exactly the same characteristics as that isolated in Case I, and gave a positive agglutination reaction with anti-serum to meningococcus Type II only. The organism was therefore a meningococcus. It was markedly sensitive to two

drops of penicillin (2 units per ml.), using the "punch-plate" technique. An eye swab taken one week later gave no growth on chocolate agar after incubation for three days. In view of the possibility of an auto-infection, if the child was a carrier, a West's nasopharyngeal swab was taken. No meningococcal colonies were obtained, though  $\beta$ -haemolytic streptococci, *Haemophilus*, and a few *Neisseria catarrhalis* strains were cultured. It was unfortunately not possible to obtain swabs from the patient's younger brother.

In both the above cases there was no complaint of a sore throat, either before or during the period of eye infection nor was any history obtainable of contact with a case of meningitis. No case of meningococcal infection (meningitic, septicaemic, or conjunctival) occurred subsequently among the family of either patient, although the boy in Case II slept in the same bed as his younger brother. It is, however, of interest that, two months later, both the brothers were attacked at the same time by bilateral pneumococcal conjunctivitis, and ten days later their father also became infected. The probability, therefore, may well be that meningococcal ophthalmia is not highly infective—a suggestion supported by the general rarity of the condition. It is, however, possible that some cases have remained undiagnosed because, as records show, confusion between this condition and blennorrhoea has been caused by direct examination of pus by the stained-smear technique only, a full cult investigation not being undertaken.

## Discussion

Cases of meningococcal ophthalmia so far reported appear to fall roughly into three natural groups:

**Primary cases:** (a) not complicated by meningitis; (b) which cerebrospinal fever follows the conjunctivitis (Re 1936; Mangiaracine and Pollen, 1944).

**Secondary cases**—those occurring as an associated infection during and/or shortly after an attack of cerebrospinal fever (e.g., Cushing, 1940).

The possibility of an ensuing meningitis indicates need for early recognition and treatment in uncomplicated primary cases. Meningococci have been isolated from conjunctiva by various workers (Duke-Elder, 1938), and is presumed that, like the nasopharynx, with which it is continuous, it acts as a "carrier" reservoir and is potential source of invasion, whether or not inflammation supervenes.

The records show that the methods of treatment adopted have been: (1) local symptomatic, with or without syster sulphonamide; (2) local sulphonamide, with or without systemic sulphonamide; (3) systemic penicillin (Herr 1945). Choice of method did not seem to affect noticeably the return of the eye to normal, but local chemotherapy would seem desirable from the point of view of removing the meningococcus from a potentially dangerous site soon as possible.

Some salient features of the condition, culled from the literature, with the addition of our own cases, are brought out in the following table.

	No. of Cases
Total cases .. .. .	2
Age group:	
Under 2 .. .. .	18
2-25 .. .. .	0
Over 25 .. .. .	10
No indication .. .. .	21
Sex:	
Male .. .. .	2
Female .. .. .	7
No indication .. .. .	8
Average duration in days .. .. .	12
Bilateral in .. .. .	5
Corneal ulceration present in .. .. .	1
Complications:	
Meningitis followed in .. .. .	2
Meningococcal septicaemia followed in .. .. .	1
Source of infection:	
History of sore throat (meningococci recovered in 1 case) .. .. .	1
History of contact with meningitis .. .. .	1
Direct implantation from throat .. .. .	1

\* Same cases.

The predominance among males is well seen, the only specifically mentioned female cases being direct contacts of meningitis. (Mangiaracine and Pollen give no indication of the sex of five of their patients.) In nearly half the cases both eyes were involved, either simultaneously or at short intervals; corneal ulceration is mentioned in one-sixth of cases; in no case was the eye permanently damaged by the infection. Meningitis is an unusual but possible sequel.

### Summary

Attention is drawn to the importance of recognizing the meningococcus as a primary cause of conjunctivitis.

Two cases in Leeds school-children are described, the first being treated eventually by local sulphacetamide and the second by local penicillin, with good results.

Some aspects of the literature are discussed.

We wish to thank Mr. John Foster, honorary ophthalmic surgeon of the Leeds General Infirmary, who was in charge of these cases, for his interest and encouragement and for his permission to publish this account. Our thanks are also due to Prof. J. W. McLeod, professor of bacteriology in the University of Leeds, to our colleagues in the department, and to Prof. A. Loewenstein for such helpful advice and criticism.

## THE BIOCHEMISTRY OF SENESCENCE\*

BY

C. P. STEWART, M.Sc., Ph.D.

Reader in Clinical Chemistry, University of Edinburgh;  
 Senior Biochemist, Royal Infirmary, Edinburgh

Ray Lankester differentiated between "specific longevity" (the expectation of life at birth of a normal individual) and "potential longevity" (the duration of life which might be expected under an ideal environment). Knowledge of the processes involved in senescence, by which term we usually imply the generalized weakening of the vitality that accompanies growing old, may be expected to narrow the gap between specific and potential longevity. No doubt a gap must always remain, for even if we knew enough to provide the ideal physiological environment with complete protection from disease, and if we had the wit to apply our knowledge, there would still be occasional accidents.

The use of the term "potential longevity" implies a belief that the life of an organism is in fact limited and that senescence with ultimate death is its necessary fate. It is perfectly possible to argue that certain single-celled organisms are potentially immortal, since, given the

proper environment, they appear to be capable of reproducing themselves indefinitely. In one experiment extending over five years a single cell of paramecium was shown to be capable of producing  $2^{3020}$  similar cells (equivalent to  $10^{900}$  times the volume of the earth), and the last cultures showed no signs of senility. But even if we admit that a complex organism such as man may be regarded as potentially immortal in the special sense that he can apparently produce children who in turn can reproduce their species, and so on *ad infinitum*, we have no reason for believing that the individual man can escape death. In studying senescence, therefore, we are not looking for the *elixir vitae*; we are seeking, from the point of view of abstract knowledge, to understand the changes produced by the passage of time; and by applying such knowledge we may hope to achieve a closer approximation between "specific" and "potential" longevity, with, in particular, an extension of the period of active and useful life. To believe in the possibility of such an approximation and to attempt its achievement is not to deny the proposition that heredity plays an important part in determining longevity. Whatever part heredity may play, be it great or small, the actual duration of life is the resultant of the effects of inheritance and environment. We may at least seek by knowledge and the application of knowledge to influence the latter.

### Changes in Basal Metabolic Rate

There are many scattered references in the literature to quantitative changes associated with old age, in the composition of body fluids, in the estimated need for particular nutrients, and in the functional capacity both of individual organs and of the body as a whole. Perhaps the best-known of these is the change in the basal metabolic rate. The "prediction tables," produced by estimating the B.M.R. of considerable groups of subjects of different ages, indicate that the B.M.R. is practically constant during adult life to the age of 40, but thereafter falls each decade by approximately 1 calorie per sq. metre per hour. The differences between the age groups are statistically significant. Since this relationship between age and metabolic rate may be of fundamental importance it behoves us to examine it very carefully before accepting it at its face value. We may believe that the average B.M.R. of 100 men in the age group 60-70 is lower than that of a similar number of men aged 30-40. But, even though gross disease be excluded, a group of 100 men may be expected to include some with pathological changes not detectable by anything short of a most rigorous clinical examination—and perhaps not even then. The number is likely to be greater among the old than among the young. Is, then, the lower average B.M.R. of the older men due not to their greater age *per se* but to the greater incidence of pathological changes which may occur at any age but are commoner among the old? This is, of course, a difficulty of interpretation which must occur in any measurement comparing the old and young when the subjects are chosen only as "apparently healthy." It is obviously a serious difficulty and one which must be faced if we are to disentangle the changes inherent in the ageing process from those due to coincident disease. It is possible to get evidence on this point. In a small number of individuals the B.M.R. has been measured at frequent intervals over a considerable number of years. In two such cases the measurements extended roughly from age 40 to 60, during which period there were no more than inconsiderable changes in height and weight; in both the B.M.R. was significantly lower at 60 than at 40, though both individuals remained in good health. In a third case, over approximately the same period, the B.M.R. did not fall, and in this case the body weight was greater and the general

\* Lecture to the Postgraduate Class of Internal Medicine, Edinburgh, June 10, 1947.

health was better at 60 than at 40 years of age. These results, though one would have preferred them from a greater number of cases, undoubtedly support the view that the B.M.R. is an expression of "vitality" and that in the absence of detectable disease it decreases appreciably in later life.

If, then, we accept the view that the observed decrease in the B.M.R. is an expression of the process of senescence, some at least of the other changes which have been reported may be related to it. For if the total energy production is decreased, a decrease in energy usage for certain of the individual processes must be postulated—there must be reduced activity in some of the directions in which energy is expended. Thus, although the secretion of gastric juice is not strictly a "basal" activity, the reduced cellular metabolic rate in old age may well be associated with the much greater incidence of hypochlorhydria (or even achlorhydria). It is stated that whereas achlorhydria occurs in about 4% of young adults it is found in some 30% of persons over 60—and one cannot imagine this phenomenon being accounted for by a differential death rate in favour of achlorhydric.

#### Other Changes

Similarly, we might consider the lowered rate of energy production as contributing to the change in glucose tolerance which appears to accompany old age. The range of the response to the ingestion of 50 g. of glucose is very different for young adults and for old. The old usually show a blood-sugar maximum later (and higher) than the young, and the subsequent fall is slower, so that in many cases the fasting level (itself higher on the average than that of young people) is not attained within the usual period of two hours. It is by no means unusual for the blood-sugar curve to be such that in a young person it would be regarded as frankly diabetic—and this in the complete absence of any of the symptoms indicative of diabetes. Apart from the question obviously raised—What is diabetes?—these findings could be explained on the supposition that in old age both absorption of glucose from the alimentary tract and glycogen formation have become less efficient, and, since both these processes involve the expenditure of energy, they could be regarded as associated with the more sluggish metabolism expressed in the lowered B.M.R. It is true, however, that other interpretations of the tendency towards reduced glucose tolerance are possible, and we shall have occasion later to refer to at least one of these.

Again, decreased metabolic activity may be considered a causative agent in the decreased concentration of plasma proteins which, with the expected accompaniment of an increased blood sedimentation rate, has been found in old age.

Some of the changes which have been reported as accompanying old age are almost certainly not factors in the process of "growing old"—that is, in the essential evolutionary processes—but are a statistical result of the more frequent occurrence among old people of diseases which may be found at any age. For example, it has been stated that the plasma non-protein nitrogen tends to rise in old age, that (as one would expect if the preceding statement were true) the blood urea is also raised, and that the urea clearance diminishes. Examination of the data shows, however, that there is no general progressive change of the blood urea or the urea clearance with increasing age; there is a tendency for the blood urea to be more often increased above the average for young people and for the urea clearance to be more often decreased. The "spread" becomes greater, suggesting strongly that the data merely express the increasing frequency of renal functional impairment.

Nevertheless, the very fact that renal failure and other "pathological" changes are much commoner in the aged than in the young indicates that, secondary though they may be to the fundamental changes involved in ageing, they may be closely bound up with those changes. Detailed examination of such functional disturbances and their age distribution might well yield valuable contributions to the solution of the major problem. The more information we can gain of the changes in old age, whether they form part of the essential process of ageing or whether they are secondary to these, the nearer we shall come to fitting together our jigsaw puzzle.

#### Nutritional Problems

In any comprehensive study of the ageing process nutritional problems must have an important part. We know a certain amount (though less than would sometimes appear) about the nutritional requirements during the period of growth. We know less about the requirements in later life. This is partly because growth itself is a phenomenon so obvious and easily measured that nutritional studies are much easier during that period than adult life, when the criteria of good nutrition are difficult to define. Partly it is due to the impression that proper nutrition during the growth period presented a problem more urgent than that of nutrition in adult life, when superficially at least, there seems to be greater tolerance of dietary variations. There are, however, some suggestions that more intensive investigation is required of the nutritional environment ideal for later life. Nor ought we to forget that senescence and growth are intimately related: a famous aphorism has it that senescence begins at birth.

Determination of the vitamin content of tissues has been possible for only a few years (and the results must still be accepted with caution), but there are indications of changes associated with age, although so far these have been demonstrated only by comparison of adult animals with young growing animals and with embryos. Extension of such investigations to old age is required, with further work on the influence of the nutritional environment on the tissue content of vitamins.

It has been shown in rats that a diet qualitatively as well balanced as possible but quantitatively insufficient for rapid growth promoted longevity and postponed the changes associated with old age. This, of course, is in keeping with the greater "expectation of life" of middle-aged people who are slightly below the average weight. Are we, then, wrong in providing (or attempting to provide) for our children a diet which not only contains the essential nutrients but is so generous in quantity that it induces rapid growth? A high-fat high-carbohydrate intake (which is in fact provided by any ordinary high-calorie diet) is by no means an unmixed blessing—it is no new idea that overfeeding may be a factor in the causation of diabetes, and various facts support the idea. Much evidence relates atherosclerosis to an excessive intake of fat and, especially, cholesterol; and there are data suggesting that the same factors may be concerned in the production of arteriosclerosis in man. Evidently research on the nutritional environment appropriate to maturity and old age may do much to diminish the incidence of serious metabolic disorders in older people, besides, in due course, contributing to our knowledge of the fundamental processes of growth and ageing. Elimination of disorders attributable to faulty nutrition would, apart altogether from incidental contributions to fundamental knowledge, undoubtedly reduce very considerably the gap between specific and potential longevity and so be of immense practical value.

### Rate of Growth

A single-celled organism implanted in a suitable medium multiplies and so grows, the rate of growth continually increasing until a point is reached at which the supply of nutrients becomes insufficient to maintain the rate; thereafter growth slackens and then ceases, and the organism eventually dies from what is, in effect, starvation, or from the accumulation of the end-products of metabolism. Man also grows, and after a period during which growth has apparently ceased he dies. His cells have not lost the capacity for new growth—a wound heals in the aged as in the young, and in animals (rats) rapid growth has been induced at an age beyond the normal life-span by keeping the animals in a state of "arrested development" using a diet deficient in lysine and supplying the missing amino-acid in extreme old age.

Now the complex and highly specialized organism man would appear to be in the position of the simple organism which is repeatedly transferred to a fresh medium (and so apparently maintained indefinitely in active growth), in that his supply of nutrients is continually renewed by his food and the excretory organs remove the end-products of his metabolism. If this were really so it would be necessary to attribute senescence and death to faulty environment. But the analogy between man and bacteria or fungi is a faulty one, for in the repeatedly subcultured colony we are really dealing with successive generations. It may be that, in man, changes in the intimate structure, which are natural in the sense that they form an essential part of the process of development, are harmful in that they ultimately affect adversely either the access of nutrient material to the cell (where alone metabolism occurs), and conversely the removal of waste products, or the enzyme systems which utilize this nutrient material.

Either of these hypotheses would account for many of the changes which have been reported as accompanying old age—the decreased basal metabolic rate, the tendency to hypochlorhydria, the decreased glucose tolerance, the increased requirements of certain of the vitamins which are concerned in enzymic activity, and so on. Equally, either would account for the increased incidence in old age of diseases which may be ascribed to metabolic disorders of particular organs—as, for example, hypertension may be the result of a failure of kidney metabolism.

### Alteration in Cell Surfaces

Whether the process of senescence can ultimately be explained in either of these ways only much further research can tell. In the meantime there are a few "pointers" which indicate that slowly developing changes in the structure (and therefore the permeability) of the cell surfaces may be of fundamental importance. Recent work has suggested that although the cells, both red and white, are present in the same numbers in the blood of old people as of young, they are qualitatively altered in the aged. The red cells, though containing the "normal" amount of haemoglobin with the "normal" oxygen capacity, have, in old age, an altered stability towards hypotonic salt solutions which must be explained as due to alteration in the cell surfaces. These changes can be explained on the basis of a decreased rate of formation of the red cells (which fits the idea of a generalized decrease in cellular activity) and a corresponding decrease in the rate of cell destruction. This implies, in the red cell population at any given time, a greater number of "old" erythrocytes than in the blood of young people. The same suggestion of a lowered rate of cell formation and destruction is implicit in the finding that in the blood of aged people there is a tendency to an increased number of multilobular polymorphonuclear cells. This amounts, as has

been said, to no more than a "pointer," but it is one that is well worth following.

Were some change in the structure of cell surfaces demonstrable as an invariable concomitant of senescence, we should need much more knowledge than we now possess of this structure, and of the factors which influence it, before we could hope to delve further into the mysteries of senescence or to control it. We would have to be on our guard against ascribing too much to changes in the concentration of any one substance at the cell surfaces: any fundamental structural and functional changes there may be due to the alteration of a single constituent, but they may equally be of multiple origin. That structural changes do occur is suggested not only by the indirect evidence already outlined but by more direct evidence. Thus it has been demonstrated for certain plant leaves that, with increasing age of the leaf, electrical stimulation causes more calcium to leave the cell cortex and appear in the vacuole. (The conclusion was reached that with increasing age more calcium is concentrated at the cell surfaces, and the hypothesis was advanced that this, altering the permeability, favours the accumulation of toxic metabolites and so senescence.) In animal tissues, too, histological methods have been claimed to show increasing accumulation of calcium at the cell surfaces.

### Conclusion

In this incomplete, and indeed sketchy, outline of some of the biochemical problems of senescence I have tried to indicate the kind of evidence which exists, the difficulties of interpreting it, and some of the directions which may profitably be taken by research. That the problems are complex is clear, but they are much more complex than would appear from this survey. For man, with his highly differentiated structure, is, in a sense, not one organism but many. His various tissues grow at different rates, in different ways, and, with different environmental demands, they age differently.

In research into the processes of ageing we must be clear as to our objects. One, of course, is the pursuit of knowledge for the sake of knowledge. Another is the application of such knowledge as we may gain. But our aim here is not merely to prolong life in terms of years; as has been wittily said: "It is for science not only to add years to life but, more important, to add life to years." There is the crux of our problem—so to control senescence that man's period of useful healthy life is prolonged, whether or not we succeed in increasing his total life-span. And I venture to suggest that such control will come, partly no doubt through study of the many degenerative diseases which more frequently affect the old, but chiefly and most completely through studies of the fundamental processes of cell metabolism and the effect of the nutritional environment on them. Among these latter studies an important place must be given to the problem of the structure and mechanism of the cell surfaces.

---

The Secretary of the Department of Health for Scotland, Sir George Henderson, speaking at the Annual Conference of the Scottish Association of Insurance Committees recently, said that there was no intention of setting up a huge bureaucratic machine to run hospitals as appendages of St. Andrew's House. The Secretary of State intended to leave the administration of the new hospital system in the hands of local people. New hospitals would be sited for maximum use of the widest area and not by accident of charity or the financial resources of a local authority. He hoped that outpatient departments would be so organized as to avoid the long queues which were common to-day. Under the National Health Service the work of the old insurance committees would be taken over by Executive Councils, which would represent the whole community and not simply the present insured population. By regrouping the areas covered the work of 54 insurance committees would be done by 25 Executive Councils.

## TEMPORARY ILEOSTOMY DRAINAGE APPARATUS

AN APPARATUS FOR DRAINAGE OF A  
TEMPORARY ILEOSTOMY

BY

R. M. T. WALKER-BRASH, B.M., B.Ch.

Lieutenant, R.A.M.C.; Late House-Surgeon, St. Bartholomew's  
Hospital

The apparatus here described was devised in an effort to relieve the intolerable unpleasantness of a temporary ileostomy, but it is easily adaptable for the treatment of other digestive fistulae. An ileostomy discharges fluid or semi-solid products almost continuously over the abdominal wall, causing marked soreness and superficial ulceration of the skin despite the use of protective pastes. After several attempts the following means were adopted to control this secretion.

## Method

The skin around the ileostomy is smeared with a suitable ointment; a mixture of castor oil and zinc cream is very satisfactory. Over this is placed a layer of lint or petroleum-jelly gauze which fits neatly round the stoma. Over the whole is fixed an ordinary Irving box. Through the hole in the lid of the box a small-bore right-angled glass tube is strapped. This is placed directly over the stoma, with a clearance of about 3-4 mm. from the mucous membrane. The distal end of the tube is attached to a suction pump, which works night and day. By this means any quantities of fluid secretion or semi-solid material are aspirated as they appear in the lumen of the ileostomy. If a large solid motion occurs the lid of the box is removed by the patient and separated from the suction-tube, which can then be swept freely round the inside of the box until all the material is aspirated. At no time, therefore, is any quantity of irritating secretion left in contact with the skin of the abdomen.

The advantages of the apparatus are: (1) The skin is protected from the persistent discharge and there is no leakage to the back or groins however profuse the secretion may be. (2) No frequent changes of dressings are required, thereby giving minimal disturbance to the patient at all times and lessening the work of the nursing staff. At night the box is inspected hourly by the night nurse, and if a large motion

FIG. 1

has occurred it is aspirated as described above without waking the patient. (3) The patient, reclining comfortably against a suitable number of pillows, is in the best position from the point of view of post-operative treatment and general nursing.

(4) The method entails the use of only such simple apparatus as is found in any general hospital.

## The Apparatus in Use

The apparatus was developed in a case of acute intestinal obstruction, for which was established an ileostomy that could not be closed for three months owing to severe general peritonitis. After the operation the skin rapidly became sore, and remained so despite all remedies. Postural

FIG. 2

drainage was out of the question owing to the grave condition of the patient. However, when the Irving box was applied the skin steadily healed. The efficacy of the apparatus was demonstrated on two occasions when the skin developed in twelve hours.

Fig. 1 shows the Irving box, suction-tube, and lint *situ*. The lid of the box has been removed for the sake of clarity. Fig. 2 shows the condition of the skin at the end of three months. There are areas of redness, but none of ulceration. The ulceration on the right of the abdomen is a result of the infection of the laparotomy scar from the peritoneal cavity.

My thanks are due to Mr. John Hosford for permission to publish this paper; to Dr. B. Wells for the photographs, to Miss E. C. Hall for the development of the apparatus, and to Miss "G." for criticism and co-operation in its use during a long and trying illness.

The Convalescent Homes Committee of the King Edward's Hospital Fund for London has recently prepared a *Directory of Convalescent Homes*. The Directory is attractively bound in loose-leaf form and from time to time further pages will be issued. Over a hundred convalescent homes in the Home Counties area are already listed, and details are given of each home further afield. Each entry gives all the information of routine, recreation, staff, number of beds, and charges. There are three indexes: the first is an alphabetical list of all homes; the second groups the homes according to whether they admit women, or children; and the third index is arranged according to the type of case with details of the various qualifications apply to patients seeking admission—religion, profession, residence, and so forth. The initial fee of 5s. for the Directory entitles subscribers to all additional pages and amendments. Further information may be obtained from the Convalescent Homes Committee, King Edward's Hospital Fund, London, 10, Old Jewry, London, E.C.2.

# SIX CASES OF CARDIOVASCULAR DISORDER WITH PERIPHERAL NEURITIS

BY

EMIL LEIGH, M.D., M.R.C.P.

*Assistant Physician, Haymeads Hospital, Bishop's Stortford*

AND

A. R. HAZELTON, M.B., Ch.B.

*Medical Superintendent, Manley District Hospital, Manley,  
New South Wales*

Six cases were chosen from among many men suffering from a common complaint in a P.O.W. camp in Siam. Typical was a healthy-looking young male who complained of breathlessness on walking on the level, palpitation, and occasional precordial pain. The symptoms resembled those of effort syndrome. A history of malaria (several attacks), diarrhoea, or nutritional oedema was obtained, but none of diseases predisposing to cardiac disorders. There was no advantage to be gained by malingering at this period, nor was there any evidence of hysteria.

## Before Thiamine

On examination, tachycardia, abnormal increase of pulse rate on rising from the recumbent position, tumultuous heart action, some impurity of the mitral first sound, a

clusive (pulse rate was reduced in 1 case, increased in 2, unaltered in 3).

## After Thiamine

Each patient was then treated with thiamine, 17,000 units being given by intramuscular injection in a period of 13 days. During treatment the men were allowed to be up and about, and no change was made in their habits, occupation, or diets.

After this treatment pilocarpine increased the pulse rate in all 6 cases (average increase, 14). Atropine reduced the pulse rate in all 6 (average decrease, 14).

The stability of the vasomotor control was increased as shown by the results of injections of pilocarpine and atropine. Apparently at the high atmospheric temperature prevailing in Siam the effect of pilocarpine is to increase the pulse rate owing to reduced blood pressure secondary to vasodilatation. Atropine has the opposite effect. The side effects—salivation, dryness, etc.—indicated that there was no error in the use of the drugs.

A fall in the recumbent pulse rate, varying from 14 to 28 per minute, occurred in 5 out of the 6 cases. The sixth remained stationary at 80. The discrepancy between recumbent and upright pulse rates fell from an average discrepancy of 16 to 8 in 5 out of 6 cases.

Abnormalities in physical signs in the heart showed improvement in 4 out of the 5 cases showing them. The pistol shot sound in the groin in the recumbent position disappeared in 2 cases, was greatly reduced in 3 cases, and remained unaltered in the remaining case. Carotid sinus

Carotid sinus irritability	+	+	-	-	++	-	-	-	-	-	+	-

pistol shot sound over the femoral artery, and carotid sinus irritability could be found. No cardiac enlargement, oedema, or anaemia was detected. The standard exercise tolerance test gave normal results in spite of dyspnoea on walking. Reduced sensibility of peripheral distribution to pin-prick and deep pressure, with sluggish reflexes and slight Rombergism, constituted the common neurological findings. Routine physical examinations were recorded and disease of other systems excluded (detailed case records are available).

The following investigations into the autonomic system were carried out and repeated after treatment with thiamine: the response of the recumbent pulse rate to atropine and pilocarpine (on separate days); ciliary fatigue-time; ergograph tests on skeletal musculature; carotid sinus irritability; dermatographia.

Before treatment with thiamine, pilocarpine 1/5 gr. (13 mg.) subcutaneously increased the pulse rate in 4 cases (average increase, 16 per minute), and did not alter it in 2. The effect of atropine 1/40 gr. (1.6 mg.) was incon-

clusive. Irritability disappeared in 2 out of 3 cases. Ergograph experiments showed improvement in all cases ranging from 68% to 800%. Ciliary fatigue time tests showed improvement in 5 cases, ranging from 33% to 500%. The sixth could not see the text and could not be tested. (The eye disturbances form the subject of a separate paper.) Examination of the C.N.S. gave evidence of partial return of the reduced function of the peripheral nerves in all 6 cases. No characteristic changes could be detected in the blood pressures, which were all normal.

Breathlessness was greatly reduced in all 6 cases. Precordial pain was reduced or abolished in 4 out of 4 who had complained of it. Palpitation was reduced or abolished in 4 out of 4. Sleep improved in 5 cases. Nocturnal frequency of micturition was reduced in 3 out of 6 (urine more concentrated in 5 out of 6). Frequency of bowel action was reduced in 2 out of 2. Appetite increased in 1 case, diminished in 1. Headaches were abolished in 2 out of 2. The improvement in symptoms began after the third injection.

It was felt that the dosage of thiamine had been inadequate, but supplies were very restricted.

### Conclusions

Thiamine benefited cases of a syndrome of cardiovascular derangement resembling effort syndrome with peripheral neuritis.

There was a disturbance of the autonomic system which appeared to be corrected by thiamine.

## Medical Memoranda

### Hypertension and Nephrectomy

Ever since Goldblatt demonstrated that hypertension could be produced experimentally by unilateral renal ischaemia, the hope has been present in the minds of physicians that some cases of hypertension would be amenable to treatment by nephrectomy. It was obvious that the necessary condition of a localized silent kidney lesion was not common, and the prospects of operative cure are correspondingly less so. Nevertheless, during the past ten years cases of pyelonephritis and hydronephrosis, and even of renal tuberculosis and neoplasm, have been reported as causing hypertension which was cured by this operation. Some American writers have suggested that 1 in 200 of all cases of hypertension fall into this category, but English opinion tends to regard this as over-optimistic. Ratcliffe, Nesbit, Plumb, and Bohne (*J. Amer. med. Ass.*, 1947, 133, 297), reviewing pyelograms on 2,055 hypertensives in the University of Michigan Hospital, found nephrectomy indicated in under 5%. Cases of hypertension found in members of the Armed Forces, being young and otherwise fit, would appear a suitable field for seeking such surgical opportunity. The following case report suggests that the search is worth while.

#### CASE HISTORY

On Nov. 7, 1944, a W.A.A.F. non-commissioned officer aged 27 was admitted to hospital with a history of headache and vomiting for eight months. The headache was worse in the mornings. There had been a slight loss of weight, but no other symptoms, in particular no urinary symptoms. Examination showed a normally developed girl with a forcible pulse and a blood pressure of 250/160. The apex beat was not palpable, the femoral pulses were easily felt, and the fundus oculi showed hypertensive change, in that the arteries were narrowed to fine threads. There was some white exudate but no haemorrhages. It appeared to me that early papilloedema was present, though on subsequent reflection I am not disposed to be definite on this point. She had no recollection of any previous illness, and her records showed that at a routine examination eleven months earlier her blood pressure was noted as 120/70. Experience has taught me, however, that the results of routine examination are not a suitable basis for scientific deductions.

**Investigations.**—The urine showed a cloud of albumin and a moderate number of red cells, but no casts. A radiograph of the pelvis revealed a heart at the upper limit of normal and a dilated

An intravenous pyelogram showed a normal left kidney but no excretion on the right. Retrograde pyelography by Squadron-Leader Gordon Lennon, surgical specialist, was reported on by Flight-Lieutenant Donnelly, radiologist, as follows: "A large hydronephrosis is present on the right side. It is of the combined intra- and extra-renal type. The right ureter appears normal. Most of the dye was retained in the pelvis five minutes after injection, suggesting a valvular action at the pelvi-ureteral junction. The above indicates that the hydronephrosis has been caused by an aberrant renal artery." The blood urea was 20 mg. per 100 ml. and the urea clearance was 118.5% of average normal (van Slyke).

**Progress.**—After a month in bed her blood pressure had fallen to 170/130 and was obviously going no lower. The consultant in surgery (Air Commodore Hall) and Squadron-Leader Lennon agreed that nephrectomy was indicated, and on Dec. 13 this was performed by the latter. Some difficulty was experienced in mobilizing the kidney, which was represented mainly by a hydronephrotic sac. Nothing untoward occurred, however, and on the day after operation her condition was excellent, with a blood pressure of 190/140. During convalescence she remarked that all headache and feeling of discomfort had gone, and that she felt well for the first time for many months. On her discharge from hospital on Jan. 8, 1945,

her blood pressure was 170/115. Three months later her health was excellent, the urine free from albumin or other abnormality, and the fundus oculi normal. Her blood pressure, however, continued to range around 180/130. It was obvious that restoration to normal had not occurred, and probably would not do so, but there was no doubt that she had been changed from an extremely sick young woman to one capable of enjoying all ordinary activities. In November, 1946, she was living a normal life free from symptoms with a blood pressure of 165/105 but no other detectable abnormality. When last seen in July, 1947, her condition was the same.

### DISCUSSION

By far the greatest number of cases of alleged hypertension referred to me from Service units were not hypertensive by ordinary standards. They represent an emotional rise of blood pressure associated with medical examination which reverts to normal when the patient is put at ease with the examiner. A few, however, as in the case quoted, have an undeniable hypertension. If surgery is to be considered, the most convenient preliminary investigation of such cases is pyelography since biochemical renal function tests, though useful later, do not give the needed information as to the anatomical distribution of the lesion. In dealing with large numbers of cases it saves time if the most selective procedure is done first. Of 36 genuine cases of hypertension that I dealt with unilateral kidney damage was found in two. The progress of one is recorded above. That of the other was cut short, after a successful operation for removal of an atrophic kidney, by an unrelated fatal illness.

### A Complication of Birth Control

The following case report draws attention to a practice that may be gaining in popularity.

#### CASE REPORT

The patient, an intelligent married woman aged 31, was admitted on May 25, 1947, from the casualty department, having passed a clinical thermometer into the bladder via the urethra. She complained of slight lower abdominal discomfort, and there was a small quantity of blood in the urine; she passed urine without difficulty but had some discomfort at the end of micturition. The accompanying skiagram shows the thermometer lying transversely across the bladder.

The thermometer was easily visualized by cystoscopy, and the temperature was seen to be 100.5° F. (38.05° C.). The patient

was put in a partial Trendelenburg position and the smallest-size infants' proctoscope was passed through the urethra. Eve's nasal snare was placed round the constriction of the bulb of the thermometer, which was then extracted. There were no subsequent urinary difficulties, and the patient was discharged on the following day.

The explanation of this occurrence is as follows. The patient had read in a magazine of the so-called "safe period" method of birth control and the relation between the time of ovulation and a variation of vaginal temperature, and she was keeping a daily chart of that temperature. For ten mornings this had shown little change. On the eleventh day she carelessly passed the thermometer into the bladder. If this practice is becoming more common, the provision of a specially designed thermometer with flange or handle would seem desirable.

JOHN HANKINSON, M.B., B.S.  
St. Mary's Hospital, W.2.

## Reviews

### "NOVAK"

*Gynecological and Obstetrical Pathology. With Clinical and Endocrine Relations.* By Emil Novak, M.D., D.Sc., F.A.C.S. Second edition, revised. (Pp. 570; 542 illustrations, 15 in colours. 37s. 6d.) Philadelphia and London: W. B. Saunders Company. 1947.

Good clinical work is based on a sound knowledge of physiology and pathology, a fact especially true of gynaecology. The relationship is admirably brought out in this book, which is perhaps the chief reason for the enthusiastic welcome accorded the first edition in Britain and for its continued popularity. It is interesting to read, simple and clear as well as informative. It has become a standard book which most gynaecologists and pathologists not only possess but refer to constantly. Those studying for higher examinations pin their faith on it. Not the least of its attractions is that although it is fairly comprehensive it is not too detailed for those whose interests are mainly practical. The author provides a few important references for those wishing to delve more deeply into any subject. The book in its original form is so well known—indeed in Britain it is usually called "Novak" without regard for other books by the same author—that it seems hardly necessary to describe it in detail. The second edition conforms closely to the first in subject-matter, style, and layout. The increased size is largely due to additional illustrations; there are nearly as many of these as pages, and excellent they are too. The author has taken care to bring the text thoroughly up to date, but has wisely avoided any attempt to make the book "exhaustive or encyclopaedic." Had he done the latter much of its charm would probably have been lost. The obstetrical section is still strictly limited in its scope.

It is doubtful whether anyone without the special qualifications of Dr. Novak could have written this book, for he is a practising gynaecologist with a wide experience and interest in pathology and endocrinology. One small adverse criticism is of the author's use of the terms vaginal and vulval *mucosa*. It is a common enough error, but it is surprising that it should be perpetuated by one of Novak's undoubted authority.

T. N. A. JEFFCOATE.

### MEDICINE INTEGRATED

*An Integrated Practice of Medicine. A Complete General Practice of Medicine from Differential Diagnosis by Presenting Symptoms to Specific Management of the Patient.* By Harold Thomas Hyman, M.D. In four volumes with separate Diagnosis and Subject Index. (Pp. 4,621, with 1,184 illustrations, 305 in colour, and 319 tables of Differential Diagnosis. Complete set £12 10s.) Philadelphia and London: W. B. Saunders Company. 1947.

"If," the editor explains in his preface, "this book fulfils the requirements for which it has been devised, it should be possible for the practitioner, after taking the history and performing the physical examination, to turn to the Index of Differential Diagnosis, obtain a reference to the needed Tables of Differential Diagnosis, establish a definitive diagnosis or be guided to additional examinations and tests by which the diagnosis can be established; and then prepare a therapeutic routine to include symptomatic, specific and prophylactic therapy for the relief or cure of the abnormal manifestation concerning which his patient has consulted him." The book is thus an attempt to substitute for the complex mental processes by which diagnosis is achieved a mechanical device which supplies the diagnosis and "therapeutic routine" when applied to the "facts" of history and physical examination. Such a procedure reduces medicine to the status of a cross-word puzzle, a mechanistic ambition curiously at variance with the author's avowed objective of focusing "consideration on the human patient as a biologic unity."

Although the author in his prolegomena appears to stress the individuality of the patient, while tacitly denying that of the doctor, it is doubtful whether this attitude reflects either American practice in general or that of Dr. Hyman in particular. The book displays the breadth of Dr. Hyman's interests and the depth of his knowledge, for he considers the whole of general practice and, in addition, the special subjects and minor and

emergency major surgery. He describes the methods of physical examination and the simpler laboratory tests, lists the occasions when a second opinion should be taken, and gives a glossary of haematological terms. It is in writing of prognosis and of how to start in general practice that Dr. Hyman reveals a humanism which belies the mechanistic claims of his preface.

This massive work contains much information, and its unusual homogeneity suggests that the editor is at least part author of all its 4,000-odd pages. It would be hard to overestimate the labour involved in making this vast compilation. The book is addressed to the American general practitioner, whose professional existence must differ from that of his counterpart in Britain, and we therefore doubt whether it is a sound investment for the general practitioner in this country.

R. BODLEY SCOTT.

### TOMOGRAPHY

*A Manual of Tomography.* By M. Weinbren, M.R.C.S., L.R.C.P., F.F.R., D.M.R.E. (Pp. 270; with 138 figures comprising 397 illustrations. 45s.) London: H. K. Lewis and Co. 1946.

The author of this book is experienced in tomography and obviously an enthusiast. After a short introduction he considers tomography of the chest, the spine, the skull, the larynx and miscellaneous conditions. His discussion of chest tomography is clear and complete. In the chapter on the spine which is, curiously, the largest in the book, he explores the subject, recording the use of tomography for conditions in which it has so far been little used. He clearly demonstrates its value in some cases; in others the standard radiographic methods show the lesion equally well; and in one or two, judging by the illustrations, the tomographic method seems to be inferior, though this appearance may be the result of reproduction. This section is instructive for its account of the possible uses of tomography in obscure lesions of the spine and pelvis. The author records its value in compression fractures of the dorsal spine, especially in the cervico-dorsal region, where satisfactory lateral views cannot be obtained by ordinary radiography.

Tomography is particularly useful in spondylitis and spondylolisthesis, where it is often difficult to show the defect in the pars interarticularis, and in fracture dislocations for revealing the relations of the articular processes. For examining the healing of fractured vertebral bodies, the progress of Pott's disease, fractures of the odontoid process, and spinal metastases the author shows that tomography is sometimes effective. He has successfully used tomography for investigating various lesions of the skull and facial bones, including fractures, sinus infections, and intracranial and eighth nerve tumours. In a miscellaneous section he describes the tomographic appearances in lesions of the sternum, limb joints, gall-bladder, and kidney. When gas obscures the picture in cholecystography and intravenous pyelography, tomograms may clearly reveal the contrast filling.

This book, which has a good bibliography, will be of great interest to all who employ tomography, for it indicates how various are its applications and suggests further extensions of the method.

S. COCHRANE SHANKS.

### SURGERY OF DIABETES

*Le Chirurgien en Présence de l'Etat Diabétique.* By Jacques Bréhant. Preface by Prof. Sèneque. (Pp. 544; 44 figures. 1,200 francs.) Paris: Masson et Cie. 1946.

This book is mainly based on the author's experience before and during the recent war. In the first section he discusses what a surgeon ought to know about the treatment of diabetes. He uses the French classification of diabetes into, without, and with loss of weight, but advocates the use of large doses of insulin for all the serious surgical complications. The most important section is that describing the diseases of the legs and toes. He describes three main types—vascular, infective, and trophic. He fully considers the value of sympathectomy in these cases and points out that if a good response to the injection of procaine into the lumbar sympathetic has been obtained and the condition of the toes is stabilized lumbar sympathectomy is indicated. He strongly advocates using a Pachon oscillogometer in determining the site of amputation. He describes successful local amputations of toes and metatarsus and the ideal and unsuitable sites for amputation.

Although he mentions penicillin it is usually in conjunction with sulphonamides—probably because the book was written during the war, and before penicillin was available. Its use may cause him to alter his views considerably about the best time to operate. Discussing whether trauma causes diabetes mellitus, he quotes the evidence of de Laet, Labbe, and Joslin, who believe that it does not, and sets it against that of Rathery; he concludes that, though it can be only an exceptional occurrence, it does. The arguments are not very convincing. The rest of the book contains a short description of most of the other surgical diseases in so far as they are modified by diabetes. There is a good index.

GEORGE GRAHAM.

## REMINISCENCES

*János. The Story of a Doctor.* By John Plesch. Translated by Edward Fitzgerald. (Pp. 579; illustrated. 18s.) London: Victor Gollancz. 1947.

John Plesch has enjoyed a life of unusual variety. Born in Budapest in 1878, he was for more than twenty years a leading physician in Berlin, but when the Nazis took over he was one of the first fugitives to arrive in England to begin a new career. His practice in a second alien capital was rapidly and remarkably successful; indeed it was, as he writes, "something of an event." His christian name gives his book its title, and this is characteristic of his expansive personality. The eminent in art, science, and politics crowd into his book as they might jostle one another at an ambassador's cocktail party. All these diverse characters have enjoyed his friendship, for János, with disarming catholicity, is moved by the simple and massive integrity of such men as Einstein and yet is not unaware of the "fabulous leg" of Marlene Dietrich, "in a wonderful silk stocking visible well above the knee." The two chapters on Einstein are the most important in the book, and, for medical readers, his reminiscences of such scientific figures as Wassermann, Schaudinn, and Ehrlich are of great interest.

He is obviously a physician who brings to his patients a genuine humanity, and the only criticism of his English colleagues which he allows himself is that they incline towards a harsh and dogmatic prognosis. His advice is, "think pessimistically and act optimistically." He caricatures his own counsel, however, in an incident he relates on another page, when, having been called to St. Petersburg to the death-bed of a beautiful Russian actress, he "fought that day as I have rarely had to fight. As soon as a medicine failed to produce a response from the sinking organism, stronger methods had to be tried. Everything possible was done, and everything depended on the two finger-tips that controlled the failing pulse. Death was delayed for twelve hours, and at the end of that time I broke down myself and wept, the relaxation of tension was so violent."

János concludes with advice on such subjects as food, fatigue, slimming, exercise, surgery, constipation, homosexuality, and the natural position in coitus. These dialogues will be more nourishing to the layman than to the medical man, but they disclose an attitude to such problems which is characteristically European—realistic, intelligent, and humane. In short this book, while by no means another *San Michele*, is, as the Sunday viewers say, worthy of the library list.

D. V. HUBBLE.

*Pharmaco-Therapeutic Notebook*, by H. W. Tomski (London: Baillière, Tindall and Cox; 15s.), is intended for the pharmacists "who served in the Forces and have lost contact during the war with professional pharmacy," and also for the general practitioner. It gives concise information on drugs used in modern practice. These appear under alphabetical headings such as anaesthetics, analgesics and antipyretics, circulatory and respiratory stimulants, diuretics, hypnotics and sedatives, purgatives, etc. The book consists of comprehensive lecture notes, and does not replace but supplements textbooks and pharmacopoeias. It includes commonly used prescriptions for some drugs and a chapter on substitution therapeutics. There is a good index.

M. A. Kamath's *Ophthalmic Surgery and Sight-Testing*, a first edition of which appeared in 1926, is an elementary exposition of the common ophthalmic conditions; in spite of its name the author does not unduly stress surgery and sight-testing. The features that he emphasizes, based on Indian experience, are rather different from those generally observed in European textbooks. Copies may be obtained from the author at Planter's Lane, Mangalore, South Kanara, South India.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Mothercraft in Pictures.* Compiled by M. Maslem Jones, S.R.N. S.C.M., M.T.S. (7s. 6d.) London: Faber and Faber. 1947.

A series of photographs illustrating care of the baby.

*Radium Dosage.* The Manchester System. Edited by W. J. Meredith, M.Sc., F.Inst.P. (Pp. 124. 15s.) Edinburgh: E. and S. Livingstone, Limited. 1947.

A collection of papers on mould, intra-cavitary, and interstitial gamma-ray therapy.

*The Social and Legal Aspects of Sexual Abnormality.* By Edward Glover, M.D. (Pp. 16. 1s.) London: The Institute for the Scientific Treatment of Delinquency. 1947.

A brief account of sexual perversion in relation to the law and society.

*Personal Mental Hygiene.* Don Thomas Verner Moore, O.S.B. M.D., Ph.D. (Pp. 331. 21s.) London: William Heinemann. 1947.

The author presents "various attitudes of mind, ideals, and principles which may be of value to the individual confronted with the difficulties of life."

*The Head, Neck, and Trunk.* By Daniel P. Quiring, Ph.D. (Pp. 115. 14s.) London: Henry Kimpton. 1947.

Diagrammatically illustrates the muscles of the head, neck, and trunk, with their chief arterial and nerve supplies.

*Radical Surgery in Advanced Abdominal Cancer.* By Alexander Brunschwig, M.D. (Pp. 324. 42s.) Chicago, Illinois: The University of Chicago Press. Great Britain and Ireland: Cambridge University Press. 1947.

An account of the author's operations on 100 cases of advanced malignant disease.

*Kompennum der Parasitischen Würmer im Menschen.* By Dr. Hans A. Kreis. (Pp. 136. 10 Swiss francs.) Basle: Benno Schwabe and Co. 1947.

A brief account of worms parasitic in man.

*Vegetative Funktionen und Zwischenhirn.* By Dr. W. R. Hess. (Pp. 65. 12 Swiss francs.) Basle: Benno Schwabe and Co.

A monograph, based on the author's experiments, on the vegetative functions of the mid-brain.

*Das Auge als Subjekt des Wahrnehmungsbild und Seine Prüfung.* By Dr. Fritz Rössler. (Pp. 190. 60 Swiss francs.) Vienna: Verlag Wilhelm Maudrich. 1947.

Examination of the eye by subjective methods, with particular reference to the cobalt lamp.

*Inter-Allied-Conferences on War Medicine Convened by the Royal Society of Medicine 1942-1945.* Edited by Major-General Sir Henry Letheby Tidy, K.B.E., M.D., and J. M. Browne Kutschbach, M.B., B.Ch., D.P.H. (Pp. 531. 50s.) London: Staples Press, Limited. 1947.

Communications delivered at conferences held by the Medical Services of the Allies.

*Electronics and their Application in Industry and Research.* Edited by Bernard Lovell, O.B.E., B.Sc., Ph.D. (Pp. 660. 42s.) London: The Pilot Press, Ltd. 1947.

Includes accounts of radar, the use of electronics in medicine and physiology, and electron-microscopy.

*The Art is Long.* By William Edwards, M.D. (Pp. 159. 10s. 6d.) London: Andrew Melrose, Ltd.

Describes for the layman the activities of medical men in general and specialist practice.

*Nursing.* By L. K. Wolf, R.N., B.S., M.P.H. (Pp. 534. 53s. 9d.) London and New York: D. Appleton-Century Company. 1947.

An account of the principles of nursing, with many diagrams.

*Biology for Medical Students.* By C. C. Hentschel, M.Sc., and W. R. Ivimey Cook, B.Sc., Ph.D. 4th ed. (Pp. 752. 25s.) London: Longmans, Green and Co. 1947.

The authors have largely rewritten this textbook emphasizing physiological aspects of botany and zoology.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 11 1947

## TREATMENT OF NEUROSYPHILIS

Since the introduction of syphilis into Europe the incidence of neurosyphilis has markedly increased. It was rare in the early days, but in recent times has become comparatively common among the white though still uncommon among the coloured races. Many theories have been advanced to account for this difference, none of them very convincing. It has been suggested that the therapeutic use of arsenicals was one cause of the increased incidence of neurosyphilis, but it now seems clear that it was the employment of a sub-optimal dosage that was to blame. In the past the treatment of neurosyphilis was most unsatisfactory, since mercury had little or no effect on any except perhaps the very early asymptomatic cases. With the advent of the trivalent arsenicals the position improved, most of the earlier types of neurosyphilis, both asymptomatic and symptomatic, reacting well, though a diagnosis of general paralysis of the insane still remained virtually equivalent to a death warrant. Later, trypanamide proved considerably more effective than any of the trivalent preparations, but it was Wagner-Jauregg's introduction of malaria therapy which first offered any hope of curing, or at least arresting, G.P.I. Since then many of these patients have recovered sufficiently to be able to lead useful lives over a period of years.

Penicillin has now further advanced the treatment of all forms of neurosyphilis. Elsewhere in this issue (p. 565) Lescher and Richards describe their results in 49 patients suffering from various forms of neurosyphilis: 20 were treated by malaria and chemotherapy, 10 by penicillin alone, and 19 by malaria plus penicillin. The first group was observed for five to eight years; 6 were much improved, 6 improved, 4 remained stationary, and 4 became worse. Cases with meningo-vascular lesions gave the best results—4 of the 5 cases being "much improved." The cerebrospinal fluid became serologically negative in 10 and inactive in 7 of the 20 cases; blood tests gave 10 negative, 6 improved, and 4 positive results. Whelen<sup>1</sup> states that after the malaria treatment of G.P.I. the cerebrospinal fluid usually becomes inactive in six to twelve months and negative in one to three years, after which relapse seldom occurs. Of the 10 cases in the penicillin-treated group, 4 were much improved, 3 improved, 2 stationary, and one patient became worse; serologically their cerebrospinal fluids gave one weak positive, 6 inactive, and 3 negative results; blood tests gave 5 positive, 3 improved, and 2 negative results. Of 19 patients treated in or after 1945 with malaria and penicillin, 9 were much improved, 5 improved, and in 5 the

condition remained stationary. The cerebrospinal fluid in these cases showed 1 strong positive, 1 weak positive, 10 inactive, and 7 negative results. There were 11 positive, 2 improved, and 6 negative blood tests, showing that it is much easier to reverse the serological findings in the spinal fluid than in the blood. On the whole the third group showed most improvement, but the numbers were too small for clear deductions to be drawn as to the best treatment for each type of neurosyphilis.

In our opening pages Worster-Drought discusses the value and use of penicillin in the various forms of neurosyphilis and points out that penicillin, arsenicals, and bismuth are probably synergistic, and that a rise in temperature—as by malaria therapy—appears to enhance the effect of penicillin. He tried intrathecal penicillin but was not convinced of its value; it often caused an exacerbation of symptoms, particularly in tabes. Penicillin certainly affected the cerebrospinal fluid, and in some cases the number of cells rose to 10,000 per c.mm. and the protein to 250 mg. per 100 ml.; this might have been due to impurities. The question of the penetration of the blood-brain barrier by penicillin has been much discussed. It is stated that penicillin will pass the barrier if it is given in massive doses or if the choroid plexus is damaged, but the problem is mainly of academic interest, since this antibiotic is undoubtedly carried to the nervous system in the blood stream, and both clinical observation and pathological tests avouch its efficacy. Obviously neither penicillin nor any other remedy can resuscitate dead nerve cells. Penicillin given by cisternal puncture is dangerous, and this method should not be attempted. But when penicillin is given intramuscularly—and this seems the best method, whether it is given in solution or suspended in oil-wax—reactions are negligible. However, Herxheimer reactions are to be feared in patients with neurosyphilis, and Worster-Drought always starts treatment with a few injections of bismuth; urticaria appears occasionally but seldom calls for the cessation of treatment.

Meningo-vascular neurosyphilis responds best to penicillin, and cranial nerve palsies often improve greatly. In cases of G.P.I. the treatment recommended is: four injections of bismuth, 4-5 mega units of penicillin, malaria (twelve bouts of fever), and then three courses, each of twelve injections, of arsenic and bismuth in one year. The Lange curve is the reaction most difficult to reverse. In the treatment of tabes 4-5 mega units of penicillin should be followed by arsenic and bismuth for one to two years; malaria is not recommended, and intrathecal penicillin should be avoided as being likely to increase lightning pains. For optic atrophy treatment by 4 mega units of penicillin, plus malaria, plus arsenic and bismuth is suggested; the same would apply to late asymptomatic cases, and treatment should be continued until the serological tests become negative. Five years is the minimum time over which observation should continue properly to evaluate the effect of therapy.

Koteen,<sup>2</sup> reporting on 111 cases of late neurosyphilis treated with penicillin and observed for twelve to thirty months, suggests that penicillin is superior to "metal chemotherapy" and probably the equal of artificial fever, except in cases of optic atrophy. Of 11 patients with G.P.I., 6 had

<sup>1</sup> *Brit. J. vener. Dis.*, 1946, 22, 121.<sup>2</sup> *Amer. J. vener. Dis.*, 1947, 31, 1.

remissions lasting two years; 4 of the 5 others had deteriorated badly before being treated. In 41 tabetics 33 out of 57 symptoms were favourably affected; and in general the pathological changes in the cerebrospinal fluid showed a marked improvement. Nicol<sup>3</sup> treated 254 men and 180 women, half with malaria only and half with malaria plus tryparsamide, and concluded that the latter form of treatment was superior to the former; this is probably the most important series reported in this country. The patients consisted for the most part of cases of G.P.I., but a few cases, of taboparesis, congenital G.P.I., and congenital taboparesis were included. If tests of the cerebrospinal fluid are positive at the end of a year following treatment further treatment is indicated, but if negative on two consecutive occasions at yearly intervals a reversion to positive reactions is extremely unlikely. Speaking in April, 1946, Nicol gave it as his opinion that penicillin will probably replace tryparsamide as an adjunct to malaria therapy.

Kampmeier<sup>4</sup> stresses the need for individual treatment of neurosyphilis; patients with type I cerebrospinal fluids need only routine treatment with arsenic and bismuth, but those with type II or III fluids need long-continued treatment with arsenicals and bismuth, supplemented by tryparsamide and fever therapy if the fluid does not improve considerably after eight to ten months. Both McElligott<sup>5</sup> and Marshall<sup>6</sup> advocate repeated courses of penicillin, and there is much to support their view; it may be that a second or third "blow" is necessary to destroy the last spirochaete, as is the case with arsenicals.

Neurosyphilis cannot be dealt with as a single problem. Early cases with only slight changes in the cerebrospinal fluid, such as occur not uncommonly in the secondary stage, react well to routine treatment. Generally speaking, however, the more marked the changes in the cerebrospinal fluid the more intensive and prolonged should be the treatment. Frequent examinations of the cerebrospinal fluid are necessary to assess the progress of the disease and the effects of treatment. Though clinical improvement by no means always goes hand-in-hand with changes in the cerebrospinal fluid, nevertheless the results of tests of the cerebrospinal fluid are the best guides to prognosis, and if the fluid shows a steady return to normal the outlook is good. It is not to be expected that serious nerve damage can be repaired, but it can usually be arrested by energetic treatment of the right type, though many of the manifestations of tabes are particularly resistant. The blood serum reactions in patients with late neurosyphilis do not tend to reverse so easily as those of the cerebrospinal fluid; in practice they may be almost disregarded. It seems clear in the present state of our knowledge that penicillin, plus fever, plus arsenic and bismuth provides the most effective treatment of late cases. Penicillin in oil-wax given once or twice daily appears to be just as effective as penicillin in solution given 3-hourly, and is much more convenient for all but hospital in-patients. Little has been reported on the relative merits of malaria and hyperpyrexia induced by physical means, but they appear to act equally well, the latter being safer but requiring more skilled staff and equipment.

## CO-OPERATION IN MEDICAL ABSTRACTS

One of the last conferences held by Unesco before the meeting of the General Assembly in Mexico was on the co-ordination of abstracting services for medical science. This conference was held at Paris on Oct. 3, 4, and 5, and the session was opened by a welcome to the delegates by the Director-General, Dr. Julian Huxley, and by Dr. J. Needham, Director of the Natural Sciences Division. Dr. Huxley gave a brief exposition of some of Unesco's recent activities, and said that the unification of abstracting systems in the medical field was a step towards forming what H. G. Wells had called a world brain. He extended a particular welcome to the representative from the World Health Organization, and, after he had concluded his address, the Conference, acting on Dr. Huxley's suggestion, appointed the Editor of the *British Medical Journal* as Chairman of the Conference, and Mrs. Eileen Cunningham of the Medical Library Association of the U.S.A., as Vice-Chairman. Among those present were representatives of *Excerpta Medica* from Amsterdam, of the British Bureau of Abstracts, of *Biological Abstracts*, Philadelphia, and the Editor of *World Abstracts*; various experts from the Unesco Secretariat, and the Director of Technical Service of the World Health Organization. Dr. I. M. Zhukov, Medical Counsellor of the Natural Sciences Division of Unesco, reviewed the steps that had been taken towards the co-ordination of abstracting services, and mentioned that the *British Medical Journal* had been the first to suggest that this was a field of possible interest to Unesco in its task of disseminating scientific information.

The Conference began its work proper with a series of statements by the Editors of abstracting journals on the development of their services, of their aims and achievements. Dr. John L. Flynn, in an interesting exposition of *Biological Abstracts*, said that it had been founded by the amalgamation of two smaller abstracting services—the Bacteriological Abstracting Service, founded in 1917; and the Botanical Abstracting Service, founded in 1918. Prof. W. P. C. Zeeman gave an account of the approach of *Excerpta Medica*, which aimed at providing a comprehensive service by the publication of about fifteen different sections for the various special divisions of medicine. An example of amalgamation was given by Prof. Samson Wright, who observed that *British Abstracts* had been formed by the unification of the services of *Chemical Abstracts* and *Physiological Abstracts*. In addition to the statements of the Editors a number of documents had been laid before the Conference, including a communication from the National Research Council, Washington, in which it drew attention to the need for co-ordinating the abstracting services in biology and medicine, for eliminating wasteful duplication, and for publication at reasonable prices. The National Research Council also suggested that amalgamation of existing non-profit making abstracting agencies on an international basis might be made possible.

After these preliminary discussions the Conference took as the principal item on its agenda a document prepared by Unesco on co-operation in scientific abstracting. It was agreed that this co-operation should be between non-profit making organizations. The Conference scrutinized the document closely, and after detailed examination of each paragraph made a series of recommendations bearing

<sup>3</sup> *Brit. J. vener. Dis.*, 1946, 22, 112.

<sup>4</sup> *Essentials of Syphilology*, 1946, Blackwell, Oxford.

<sup>5</sup> *In Penicillin*, 1946, Edited by A. Fleming, London. P. 278

<sup>6</sup> *Proc. roy. Soc. Med.*, 1946, 39, 465.

on the question of collaboration. It was made clear by all the delegates present that they had no authority from their respective organizations to commit themselves to effective action at this stage. The delegates, who will receive a full précis of the proceedings, will report back to their constituent organizations with a view to finding out how far each one may be prepared to go in a co-operative venture which may resolve some of the existing difficulties in medical and biological abstracting. As the meeting progressed it soon became clear that there was much overlapping of effort and much need, also, for a clearer definition of some of the terms used in recurrent discussions on the abstracting of medical literature. For example, the word "comprehensive" is frequently used without anyone being clear as to what exactly this means, and after this had been debated the Conference passed a resolution that: "A comprehensive abstracting service in the sense of abstracting all articles of all journals is impossible and undesirable." It went on to agree that a medical abstracting service should be comprehensive in the sense that it *surveys* the whole of the world medical literature. Such a survey, it was agreed, should include those sciences having a bearing on medicine, and an attempt should be made to secure the co-operation of abstracting services of non-medical sciences in the hope that these would indicate to the medical services matters of possible medical interest. An example given of this need was the appearance in a journal devoted to electrical engineering of an article on electro-cardiography.

The Conference was impressed by the fact that in these days there was hardly any science whose work did not find at one point or another an application in the theory and practice of medicine. The need of the consumer was laid prominently before the Conference. First, of course, was the need for information. Secondly, it was felt essential that the consumer should be able to have this information at the lowest possible cost, and so that this should be possible it was felt desirable to eliminate profit-making wherever practicable. Such elimination is, of course, more easily within the reach of professional organizations either acting singly or working together in groups.

As the Conference proceeded it became clear that there were a number of points at which collaboration could be effected between the biological abstracting services among themselves and between the medical abstracting services among themselves, and also between these two principal groups. It is hoped that these possibilities will be explored during the next few months and that the various organizations concerned may agree to put such co-operation into effect, possibly on an experimental basis for a year or so in order to see whether what are undoubted practical difficulties may be overcome. Although there were points of disagreement, as, for example, on the value of an author's abstract, the Conference after two days of solid work felt so encouraged by the progress made that it decided to recommend that an Interim Co-ordinating Committee on Medical and Biological Abstracting should be set up under the auspices of Unesco. On this Committee, in addition to representatives of the abstracting services, it is hoped to have among its members representatives of the World Health Organization, of the International Federation of Documentation, of the International Federation of Library Associations, and of the Medical Library

Association. It was recognized, too, that there are other long-standing abstracting organizations representing more specialized branches of medicine not yet taking part in these preliminary discussions that should be represented on a committee of co-ordination if it does prove possible to secure agreement on the various proposals for collaboration. For this reason the Committee has been termed "Interim."

The fate of Unesco is indissolubly linked with the fate of UNO. If UNO can tolerate its existing discords and still remain in being then Unesco may be effective in furthering its object—to promote world peace and understanding—with some fair chance of success. Relating its activities to the more remote and idealistic conception of world peace and understanding, the conference on abstracting felt that it might have a part to play by disseminating information on the medical and biological sciences through the various professional groups in different parts of the world, thus bringing them closer together in a field where politics is much less obtrusive.

### SYMPATHETIC DISORDERS IN POLIOMYELITIS

Acute poliomyelitis often causes pain in the limbs, which is sometimes remarkably persistent. Because it is often evoked or aggravated by movement of the affected part this painful state is loosely referred to as "spasm" even though muscle spasm as usually understood may not be apparent. The pathology of these painful disorders is unknown; even the site of origin of the pain is in doubt, though it is generally assumed to be in the muscles. That certain of the affected muscles are in an irritable state can no longer be questioned. Though a muscle may appear to be completely paralysed, it may show electromyographically that irregular action-potentials are being fired off when the muscle is apparently at rest, and a great burst of them may appear when the muscle is stretched. Such a muscle is painful, and the pain is a serious obstacle to effective treatment.

Any observation throwing light on this strange condition is welcome, and in this connexion the work of Collins, Foster, and West<sup>1</sup> is of considerable interest. In the course of treating American Service patients suffering from poliomyelitis they made use of paravertebral sympathetic block for the relief of vasomotor and sudomotor disturbances. As would be expected, the effect of procaine anaesthetization was, while it lasted, the same as that of ganglionectomy. Cyanosis gave place to flushing and warmth of the skin; the skin became dry, and oedema disappeared gradually. These effects were of much longer duration than could be accounted for by the anaesthetic action alone. After the first block the improvement lasted for about three days, and even longer after subsequent injections. The authors do not distinguish very clearly between objective and subjective improvement, but the latter at all events often persisted for as long as ten weeks after the third injection. A remarkable change occurred in three cases showing muscle spasm, tenderness, and pain; the sympathetic block gave complete relief, which was much appreciated by the patient. In one case in which the painful disorder was severe and involved both lower limbs the first injection arrested the pain and spasm only on the side of the injection; relief on the other side followed anaesthetization of the corresponding lumbar ganglia. These findings suggest that the painful irritative phenomena of poliomyelitis may be vascular in origin. It is well known that applications of heat to the painful limb often give great relief, relief that must surely be due to

<sup>1</sup> *New Engl. J. Med.*, 1947, 235, 694.

increased vascularity of the part. Perhaps some of the more puzzling phenomena of poliomyelitis may be solved by investigation of the part played by the sympathetic nervous system.

### CONVALESCENT HOMES

The Institute of Almoners, through a committee of its members headed by Miss C. Morris, the almoner of the National Hospital, Queen Square, has lately undertaken a survey of the convalescent homes of England and Wales. There were 318 of these homes, with approximately 14,000 beds, known to be open in the middle of the present year; 270 have been visited by this energetic committee, and in 12 cases the visitors were refused admission. Convalescent homes have developed without co-ordinated planning or supervision. They are unevenly distributed; the greater number are on or near the southern and south-eastern coasts. Wales is inadequately served, and the barest region of all is the north-east, with only nine homes providing 420 beds. The homes are subject to a seasonal ebb and flow—waiting-lists are longest in the summer. It is said that some patients in the Midlands have to wait six weeks to two months for admission, and, in fact, nowhere is it possible to find immediate vacancies except in winter. There is, too, a tendency for some homes admitting elderly convalescents to become homes for semi-chronic cases; sometimes the convalescents and the chronic sick are cared for in the same wards, and this may give rise to a depressing atmosphere which is the very opposite to what a convalescent home should convey.

Most of the homes, according to their own statements, take general post-operative and medical cases. The almoners say that the provision for patients with gastric conditions requiring dieting is not adequate; that cases of cardiac disorder are accepted only in a few homes; that until recently there has been no convalescent home for patients suffering from fits; that it is very difficult to place patients with asthma or those suffering from pulmonary tuberculosis; and that there is hardly any provision for skin or for cancer cases or for patients with colostomies. The majority of homes also decline to take cases needing treatment in bed or nursing attention at night. Little treatment of any kind seems to be given, and a visiting doctor usually attends once a week, or when required. The number of homes where any but minor dressings are undertaken is very small. Occupational therapy is mentioned only in connexion with five homes. Other criticisms are that often the buildings are old or ill-adapted for their purpose, living rooms have a bare appearance, and there is lack of variety in the diet. The last of these faults is perhaps excusable at present, though there is room for imagination in the preparation and serving of food in many institutions, especially among convalescent patients whose appetites require coaxing. In many homes the rules are too rigid. The strict regime of the hospital is out of place in the convalescent home. Breakfast in bed was found to be usual in only six homes, though in nearly half of those visited the management was prepared to give breakfast in bed if required. The hour of rising is sometimes far too early; in one home patients have to get up at 6.30 a.m. The last meal may be taken in the late afternoon, and in many homes no hot drink is served at bedtime. Some homes have the nonsensical rule which forbids men and women in the same establishment from meeting or going out together.

The Institute of Almoners has again performed a useful piece of work. The majority of these institutions are voluntary, many of them connected with trades and professions, some with religious groups, others with social

agencies, some twenty or thirty with voluntary hospitals, and a smaller number with hospital contributory schemes. The National Health Service Act, in so far as it concerns itself with the after-care of the patient, places the responsibility for making arrangements upon the local health authority, which may, with the approval of the Minister, contribute to any voluntary organization formed for the purpose. Unfortunate convalescent surroundings may go far to undo all that the best hospital has done, and this report implies that there should be set up some minimal standards for convalescent homes.

### PANCREATITIS

Inflammatory diseases of the pancreas are not common, and our experience is usually confined to acute and chronic pancreatitis. The first of these, acute pancreatic necrosis, occurs as a sudden and often dramatic abdominal catastrophe. Chronic pancreatitis is less clearly defined: it may give rise to an indefinite dyspepsia the nature of which is often not apparent until steatorrhoea or calcification in the pancreas is detected. In both these disorders infection of the biliary tract is usually present and is thought to be the precursor of the inflammation in the pancreas. Recently Comfort, Gambill, and Baggenstoss,<sup>3</sup> of the Mayo Clinic, have described 29 examples of what they call chronic relapsing pancreatitis in patients who showed no signs of associated disease of the biliary or gastro-intestinal tracts. The chronicity of the disorder was shown by one case in which there were symptoms for over twenty years with recurrences at intervals of from two days to nineteen years; the pancreatitis was proved by histological section. In all the patients there was a transitory disorder of pancreatic function during the acute exacerbations, though in remissions all tests might be negative. In those, however, in whom single attacks were severe or in whom recurrent attacks led to progressive destruction of the organ permanent pancreatic insufficiency resulted, and there might be diabetes, steatorrhoea, or pancreatic calculi. In a few instances all three of these sequelae developed.

In all at least 89 cases were admitted to the Mayo Clinic between 1939 and 1943, but a close study was made of only 29. Twenty-five of these were males and only 4 females, in sharp contrast to infections of the biliary tract. One-third of the patients took alcohol in excess, and in four instances a drinking bout preceded the attack. Usually this type of pancreatitis began with acute pains in the epigastrium or right hypochondrium, though in some the pains generalized. Radiation to one or other shoulder tip was not uncommon. The pain was steady rather than colicky, and it was often so severe as to require repeated injections of morphine. Sometimes it subsided within a few hours, but in six cases it persisted for four or five weeks. Nausea and vomiting, diarrhoea or constipation, fever with occasional rigors, and jaundice occurred, and in two cases there were haematemesis and melaena. Some of the patients became very shocked. Tenderness and muscle spasm were usually confined to the epigastrium, more often on the left than the right, but true abdominal rigidity was not observed. Other physical findings included enlargement of the liver or spleen and the development of a pancreatic cyst or of persistent jaundice.

Laboratory findings were inconstant. Leucocytosis was uncommon, even in an acute episode; hyperglycaemia and glycosuria, an increase in the serum bilirubin, a raised serum amylase or lipase, and steatorrhoea were all found in some of the patients, though the diagnosis was made in

<sup>3</sup> *Trans. Amer. Soc. Heat. Vent. Engrs.*, 1939, 45, 161.  
<sup>4</sup> *Gastroenterology*, 1946, 6, 239.

many instances from the clinical history alone. Occasionally the abnormalities persisted during remissions, but more often there was a return to normal between attacks. In half the cases a skiagram showed calcification of the pancreas.

The pancreas was described as being firm at operation, or hard and nodular like a carcinoma, or showing a diffuse oedema. In only one case was there haemorrhagic necrosis. These changes, and calcification or calculi formation, might be localized to the head, body, or tail of the organ, or generalized throughout its length. When the head of the pancreas was involved and the common bile-duct compressed there were dilatation of the biliary system and jaundice. Histologically there was pronounced fibrosis of the pancreas, with cellular infiltration and varying degrees of atrophy and disorganization of the acini and islet tissue.

The results of treatment were uncertain. Medical treatment by means of a diet, with the addition of pancreatin or insulin when these were indicated, would control the sequelae of the disease but did not prevent recurrences. Twenty-two of the cases came to operation; various procedures were tried, but drainage of the gall-bladder, either externally or into the duodenum, appeared to be the best method. It was followed by complete remission of symptoms in 7 and by improvement in 4 of the 17 cases in which it was done.

The authors' claim that the symptoms of chronic relapsing pancreatitis are so striking that its recognition is a simple matter may be true if the doctor is aware of its existence and if there is a history of previous attacks; in a first or isolated attack the diagnosis must always be difficult. A knowledge of its existence may be important for two reasons: first, as an alternative diagnosis to a suspected perforated peptic ulcer, since many of these cases appear with all the signs of perforation except the characteristic board-like rigidity; and, secondly, as an alternative diagnosis to carcinoma of the head of the pancreas. Although severe pain is usually the leading symptom it may be slight or even absent in chronic relapsing pancreatitis, so that biopsy of the pancreas and drainage of the gall-bladder may completely alter the prognosis in what appears to be a hopeless case of malignant jaundice.

### CARDIO-PULMONARY FUNCTION AFTER PNEUMONECTOMY

The great advances made in thoracic surgery in the last decade have been largely in surgical technique and in knowledge of the anatomy of the lung. Now probably a stage has been reached when further advances will have to follow a greater knowledge of respiratory physiology, a relatively unexplored field. Bronchspirometry is likely to give much information about loss of respiratory function, and this application of physiology to the recently gained knowledge of pulmonary anatomy will help surgeons to know what procedures can be carried out safely. Estimates can also be made of the respiratory function left to patients who have had a pneumonectomy and lobectomy in the past.

Cournand and his colleagues<sup>1</sup> have just published the results of their studies of two boys and two girls in whom left pneumonectomy was performed for pulmonary supuration ten years ago. In two of the cases a radiograph of the chest showed no evidence of distension of the right lung as judged by the position of the trachea and heart and the absence of mediastinal herniae; in the other two cases there were mediastinal herniae. Further, on screening, the range of movement of the right diaphragm in

the first two cases was small. Physiological studies were made repeatedly on these two patients between 1940 and 1946. The measurements included lung volume, pulmonary emptying rate, and maximum breathing capacity; ventilation and respiratory gas exchange under basal conditions, during and after a moderate type of exercise, and during the last minute of an exhausting type of exercise; and the state of respiratory gases in the arterial blood, at rest and immediately following completion of the moderate and the exhausting exercises. The techniques used for these studies were those previously described by Cournand.<sup>2,3,4</sup> In the two cases which showed no distension radiologically the measurements of lung volume also showed no increase. The volume changes between full expiration and inspiration revealed that the remaining lung expanded more than one of a normal pair of lungs, presumably because there was no contralateral lung to prevent expansion into the opposite chest. The figures obtained by measuring the pulmonary emptying rate strongly suggested that at rest the ventilation of the various parts of the lung was equal even in the cases with distension of the lung. Since the residual air in the distended lungs was increased—and it is constantly found that as the ratio  $\frac{\text{residual air}}{\text{total lung capacity}} \times 100$  increases the

ventilating efficiency decreases—it was not surprising that the maximum breathing capacity was relatively smaller in the two cases with pulmonary distension than in the other two. Accordingly the breathing reserve during the last minute of exhausting exercise was much smaller in the cases with pulmonary distension.

Important observations were made on the oxygen saturation of the arterial blood. In all four patients at rest and after moderate exertion the blood was fully saturated; but in the two cases with pulmonary distension the arterial blood saturation immediately after the exhausting exercise was at the low levels of 83 and 84%, compared with 92 and 93% for the two cases without distension. There was in fact a marked anoxia which caused rapid muscular fatigue and mental lassitude. This occurred despite the fact that the CO<sub>2</sub> output and the oxygen intake in the alveoli was normal. The right heart was catheterized, and the systolic and diastolic pressures in the pulmonary artery were within the normal limits—findings which indicate that the total blood flow through the lung was approximately the same as that of the normal blood flow through two lungs. This normal pressure-flow relationship may be achieved by an increase in the number of capillaries and in their size. An increase of only 16% in the diameter of the capillaries would allow 100% increase in the pulmonary blood flow without any change in pressure in the pulmonary artery.

It is clear from these observations that pulmonary distension after pneumonectomy is not a compensatory process; in fact, it produces considerable disablement, and surgical ingenuity must be directed to its prevention. It depends strictly upon the prevailing mechanical condition, and in this the flexibility of, and the presence of weak points in, the mediastinum are the most important factors. In adults attempts can be made to keep the mediastinum in its proper place by means of thoracoplasty, which not only does not impair the efficiency of ventilation of the chest but may improve it by reducing the pulmonary distension. In children, however, thoracoplasty is a crippling operation, and other means must be sought for keeping the mediastinum in its proper position; perhaps it could be achieved by the introduction of air or oil into the hemithorax on the side of the pneumonectomy.

## A NEW SWISS OTOLARYNGOLOGICAL CLINIC

BY

E. D. D. DAVIS, F.R.C.S.

Many of the hospitals in this country are planning to rebuild or to reconstruct their buildings. It is hoped that the otolaryngological departments will have a full share in this necessary reconstruction. I have recently returned from a visit to the two newest Swiss hospitals at Zurich and Basle. I was very much impressed by Prof. Nager's new otolaryngological clinic at the Canton and University Hospital, Zurich, and decided that a description of the clinic would be useful.

### The Canton and University Hospital, Zurich

This new hospital is being built in sections in an open park on the site of the old one. It is situated on a steep incline, in a broad tree-lined avenue opposite the University buildings, and is about fifteen minutes' walk from the centre of Zurich. It will consist of one large central building of five stories, linked by bridge corridors to about five four-story buildings. A model of it is displayed in the entrance hall of the new polyclinic.

The polyclinic, or out-patient department, is only new building completed, and I spent separate days inspecting it. It is a four-story structure, with a long façade set back from main avenue (Fig. 1). I had the good fortune to know Prof. Nager, the director of the otolaryngological clinic, and he kindly gave up more than two hours of his valuable time showing me round. He has spent nearly fifteen years planning this new building, and for the result merits the highest praise. He insists that the medical staff should plan their own departments in collaboration with the architects, who would carry out their desires. It is essential that both medical officer and architect should visit other new hospitals, such as those at Stockholm.

The main entrance is on the ground floor in the centre of the building and has two sets of metal-and-glass swing-doors. This entrance opens into a large oblong hall, well lighted by large windows on both sides. On the street side there is a spacious registration office separated from

the hall by a glass-panelled partition. At the farther end is a waiting-room, at the near end a separate entrance to the clinic for students. The entrance hall covers a large part of the ground floor. The building is air-conditioned and sound-proof, and has panel central heating. As there was 12° C. of frost in Zurich it was a good test for an air conditioned centrally heated building. Both air and heat are excellent. During the winter in Switzerland air-conditioning is very necessary, but in summer the windows are opened both in the hospital and in the new Basle hospital. The straight, broad, well-lighted corridors are excellent. The walls and ceilings are lined with sound-proof panels which are easily removed for ready access to the pipes and electric wires etc., placed in the ceilings.

### The Otolaryngological Clinic

This occupies the second and third floors. A broad, well-lighted, straight and spacious sound-proof corridor passes from end to end of the clinic (Fig. 2). In the centre of this corridor is a roomy entrance lobby, with large windows and giving access to the lift and staircase. Immediately opposite the staircase, over a glass-panelled door of the large office of the secretarial staff is a clock. This office is separated from the corridor by a well-designed wood-and-glass partition, and anyone inside has a view of the corridor and its entrance. Adjacent to the secretarial office the director, Prof. Nager, has his suite, consisting of a large consulting-room with a smaller room for examining patients, an experimental research laboratory, a histological laboratory, and a third laboratory for microscopy. The laboratories are presided over by a skilled lady technician. On the opposite side of the corridor is a waiting-room, with the necessary cloak-room and lavatory accommodation for the director's private patients. On the other side of the secretary's office is a library of ample size. All these rooms have communicating doors. At one end of the corridor are two operating theatre suites, a special theatre for endoscopy, a room for labyrinth tests, etc., and a camera silentissima for hearing tests research and audiometry.

On the side of the corridor opposite to the director's laboratories is the sisters' room; a series of small rooms for treatment such as short-wave diathermy, light treatment, and an inhalatorium with electrically heated inhalers; and a large waiting-room. Next to the last-named is a spacious and well-lighted

FIG. 2.—Standard corridor connecting with the future ward block. Ceilings are reduced from the normal height of 3 metres to 2.45 metres by means of removable panels providing space for installations and reducing echo. The floor-covering is of cork sections.

out-patient clinical room (Fig. 3). This has nine sets of open cubicles for examination, separated into two groups of five and four by a room for washing and sterilizing instruments, etc., with a glass-panelled partition and door. There are surgeons' washing-basins within easy reach of every cubicle. Each cubicle is well equipped with double electric-lighting sets—one for the forehead reflecting mirror and the other a switch-board for head-lamp, transilluminator, cautery, etc.—a small sterilizer, a spittoon, a glass-door cabinet for special instruments, a trolley for small trays for examining instruments, dressings, and drugs, a small pull-out writing-table; in fact, a complete outfit for the examination and minor treatment of any ear-nose-and-throat patient. All this equipment is mobile. Each cubicle has an electric-light indicator signalling by numbers: 1, to summon the nurse; 2, to summon the next patient; and 3, to summon the secretary. In addition to the large waiting-room there are two recesses, opposite but not in sight of the examining cubicle, for three or four patients about to be seen or for a patient having cocaine or other local analgesic. In line with the recesses is a secretary's office, nurses' room, and lavatories. A record office and a series of small rooms for a speech clinic and for the treatment of defects of speech are near by. Immediately beyond the out-patient room is a narrow passage about 60 ft. (18 m.) in length, isolated by swing-doors, for the testing of hearing of the voice, whisper, etc. On the farther side of this passage is a small theatre for tonsil and adenoid operations and a complete suite of rooms for the recovery of these patients, who remain the whole day, or longer if necessary. Adjoining this suite is a recreation room and bathroom, etc., for nurses. There is a terrace balcony or solarium on the roof, and balconies are placed wherever practicable and desirable. There are many more details of equipment and accommodation which are better seen than described.

The 60 beds of the otolaryngological clinic are temporarily placed on the next floor, but the clinic is to be connected to the in-patient block for the special departments, and in future the beds will be on the same floor level as the theatres.

The director sees and treats all his private patients at the clinic. He does his hospital work usually from about 8 a.m. to 12 noon every day, and sees his private patients in the afternoon. He teaches students in the afternoon in the students' clinical and lecture theatre, where there are about thirty lamps and places to examine patients. From 60 to 150 students each year do a three-months session. The course is for three years, and they have to pass an examination in otolaryngology. The complete qualifying period for medical students is 6½ years. The director is given full secretarial assistance and is encouraged to do, and is given every facility for, clinical research and private practice. All the departments of the hospital are to have this generous accommodation and equipment.

#### Conclusion

The outstanding features of the new Swiss hospitals are:

- (1) The well-designed entrances and exits, with imposing well-lighted entrance halls.
- (2) The straight broad corridors, efficiently heated, air-conditioned, sound-proofed, and well lighted by windows. As many large windows as possible, glass-panelled doors, and glass-panelled partitions of the secretarial and registration offices and day rooms conserve the light. There are no "tube station" passages and no spots of congested traffic.
- (3) The recreation or day rooms on each floor, the numerous balconies, and the roof solaria, which are well placed and designed.
- (4) The provision by the Swiss authorities for their medical staff of every facility for private and hospital practice and for clinical research, as well as secretaries and technical assistants. These facilities are also now provided for those departments which have not been rebuilt.

FIG. 3.—Northern half of the main treatment room of the E.N.T. clinic, with five treatment chairs. Sterilizing-room adjoins on right. Apparatus, desk, plumbing, etc., mounted on transversely placed units so that the treatment chairs are separated off while the unity of the room is preserved. Service passage alongside windows.

The medical officers have taken an active part in the planning and designing of their own departments, particularly with regard to such details as the placing and allocation of rooms, equipment, labour-saving devices, etc. This responsibility of planning is accepted with enthusiasm by all the medical officers concerned.

## ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

### Conferment of Honorary Fellowships

On the occasion of the grant of the Royal Charter to the Royal College of Obstetricians and Gynaecologists by H.M. the King this year the opportunity was taken to confer the Honorary Fellowship on the four surviving signatories of the articles of association whereby the College was incorporated—namely, Prof. J. M. Munro Kerr, Prof. C. G. Lowry, Sir Ewen Maclean, and Sir William Fletcher Shaw. The ceremony took place at the College, 58, Queen Anne Street, on Oct. 3. The President first paid a tribute to the signatories who had died—namely, Dr. H. Russell Andrews, Prof. W. Blair Bell, Sir Comyns Berkeley, Sir Francis Champneys, and Dr. T. Watts Eden.

Prof. Munro Kerr was introduced by Prof. R. H. Lennie, who spoke of Prof. Kerr's occupancy of the Muirhead chair of obstetrics and gynaecology at Glasgow University, a post which he held for sixteen years, and latterly his regius professorship at the University. Sir Eardley Holland introduced Prof. Lowry, emeritus professor of midwifery in the University of Belfast, where he had exerted a most beneficial influence on Irish medicine. The next recipient was Sir Ewen Maclean, introduced by Prof. G. I. Strachan, who spoke of Sir Ewen's work in the University of Wales and also of his wise counsel in all matters that concerned the Royal College. Finally, Mr. G. F. Gibberd, in introducing Sir William Fletcher Shaw, said that the very inception of the College was due mainly to his inspiration.

Sir William Fletcher Shaw, replying for the four Honorary Fellows, said it had been discovered recently that in the last century a number of obstetricians had suggested the foundation of such a college. Many of the leading obstetricians of that time had made suggestions which would have greatly improved the teaching and practice of obstetrics, but almost invariably the physicians and surgeons had joined together to prevent those suggestions from being carried out. The obstetricians, realizing that this was due to their opponents being organized in Royal Colleges, were of the opinion that they

ought to have a college of their own; but nothing had then been done in the matter, and the foundation of the present Royal College had come about in an entirely different way. Later it became obvious to some of them that something must be done to prevent the complete separation of obstetrics and gynaecology, and it appeared that the best course was to form some central body, preferably a college, which would bind together all those obstetricians and gynaecologists who believed in the indivisibility of the two subjects, and through the portal of which all must pass who wished to practise this particular branch of medicine.

He went on to speak of the early difficulties in the way of the formation of such a college. In the early 'twenties the support of the Gynaecological Visiting Society, whose members occupied almost every chair in this subject in the British and Irish universities, was enlisted, and a committee of four—Prof. Blair Bell, Sir Ewen Maclean, Sir Comyns Berkeley, and himself—was appointed to report on the matter. In 1927 the matter was made public, and opposition by the two existing Royal Colleges began and continued for the next two years. Finally, in September, 1929, the College received its registration from the Board of Trade. Those who had founded the College had handed on the torch to a new generation now being admitted to its membership. Whether it progressed or retrogressed would depend upon the amount of interest which the young people took in it and the sacrifices they were willing to make in its behalf. He and his colleagues had no fear for its future.

#### Dinner

In the evening Mr. W. G'lliatt, P.R.C.O.G., presided over a dinner at the Connaught Rooms. Mr. Aneurin Bevan, Minister of Health, proposing the toast of the Royal College, said that he had learnt from the newspapers that he was being moved about, and in the last few weeks he had been associated with every office under the Crown. He hoped that he would be spared to carry to maturity the great schemes which the Ministry of Health had launched. Mr. G'lliatt, in reply, referred to the ceremony which had taken place in the afternoon and described a project which was already under way for earmarking resident appointments for postgraduate students from the Dominions.

The toast of "The Guests" was proposed by Dr. H. R. MacLennan, of Glasgow, and Sir Herbert L. Eason and Mr. F. A. Maguire, of Sydney, replied. Mr. Maguire, who is chairman of the Regional Council in Australia of the Royal College of Obstetricians and Gynaecologists, gave some account of the present difficulties in medical education in Australia. Sydney in a normal year had 150 medical students. To-day there were 700 second-year and 800 first-year students. This problem continued into the postgraduate field. He referred appreciatively to Sir William Fletcher Shaw's recent tour of Australia and New Zealand and underlined the importance of continuing such links between Great Britain and the Dominions.

### FIRST EUROPEAN CONGRESS OF RHEUMATOLOGY

The first European Congress of Rheumatology was held at Copenhagen on Sept. 3-8 under the presidency of Prof. C. Holten, of Aarhus, Denmark. There were 400 delegates representing 25 countries, and guests of the Congress also came from Egypt, America, and Canada. At a meeting held before the Congress a European Section of the Ligue Internationale contre le Rhumatisme was founded on the same lines as the Pan-American Section formed during the war. Dr. M. P. Weil, of Paris, was elected the first president; Dr. W. S. C. Copeman (Britain) and Prof. B. Prusik (Prague) were elected vice-presidents; and Prof. E. Jarlov and Dr. K. Kalbak, both of Denmark, the secretary-general and the secretary respectively. It is hoped that the next congress of this body will be held in Prague in 1948.

At the opening session, for which the great town hall was packed, H.M. the Queen of Denmark was represented by H.R.H. Princess Caroline Mathilde, and the Ministers of Health and Social Affairs spoke of their daily contact with

the rheumatic diseases as a social problem of considerable magnitude. The help of their departments is already officially pledged to the campaign which enlightened public opinion has forced on them. The president then gave his inaugural address, and pointed out that the field of clinical observation has not yet been exhausted in this disease group. He emphasized the importance of correlating the recently gained knowledge of associated diseases such as periarteritis, myositis, and scleroderma, as well as of peripheral vascular and sympathetic nervous physiology. He referred to the increasing interest of the public in this group of diseases and their demand for action in Denmark and Sweden. All this increases the need for rheumatologists to take stock of their position and to combine to fill the many gaps in their knowledge of this new specialty. To aid in this respect is the object of the new body, whose aims are the exchange of current knowledge and the organization of team investigation in every country through the national branches and, in this country, through the Empire Rheumatism Council.

The outstanding contribution in the session which followed was that of Dr. G. D. Kersley (Britain) on the morbid anatomy and histology of rheumatic lesions. He confirmed the work of Freund and others in 1946 on the existence of a specific type of lesion in rheumatoid arthritis which occurs in any or all of the muscles of the body at any stage of the disease as well as in other mesodermal tissues and around the peripheral nerves. The lesion consists of a perivascular accumulation of lymphocytes, with degenerative and proliferative changes in all the coats of the small blood vessels and degenerative changes in the muscle fibres. He also spoke of nodule formation in various types of rheumatism; and he suggested the probability of a dual pathology in "fibrositis."

Most of the scientific contributions dealt with the question of the anti-streptolysin titre and similar antibody responses in both rheumatic fever and rheumatoid arthritis, notable among these being the papers of Winblad (Sweden), Kalbak (Denmark), and Prof. Svartz (Sweden). It is evident, however, that no finality of opinion has been reached on this subject.

The next session, under the chairmanship of Dr. W. S. C. Copeman (Britain), was devoted to the treatment of rheumatoid arthritis by means of gold salts and chemotherapy. This was introduced by a useful contribution by O. Steinbroeker (U.S.A.) on the criteria which should be employed for the assessment of results by these means. A full account of the subject by J. Forestier was presented by Coste (France), and confirmation of the value of various gold salts in rheumatoid arthritis came from papers by Secher (U.S.A.) and Clemmeson (Denmark), Sunderlin (Sweden), Kuipers (Holland), and Döbelie (Switzerland). Much less optimistic accounts came from Schlesinger (Britain), who was speaking principally of Still's disease, and from some speakers in the discussion.

The third and fourth sessions, under the chairmanship respectively of Prof. F. Coste (France) and Dr. Van Breeman (Holland), discussed various aspects of the social background of the rheumatic diseases, and the outstanding biochemical problems of rheumatism. In the former category important new statistics were produced from France, Sweden, Switzerland, Denmark, and Eire, and, in the latter, papers were read by Prof. de Sèze (France), Edström and others (Sweden), and Prof. Dirisu (Turkey). Papers on various other subjects (limited to ten minutes) were also presented by a number of delegates, including representatives of Belgium, Norway, and Czechoslovakia.

The Congress then moved from Copenhagen to the University of Aarhus on the mainland, where it split up into two sections, and reports of personal investigations into various aspects of rheumatism were briefly presented. These included liver tests in rheumatism, studies in the peripheral circulation of rheumatism, food allergy in rheumatoid arthritis, dental infection and joint disease in mediaeval Denmark, rheumatic fever among the partisan forces of Yugoslavia, jaundice as a "rheumatic" disease in Poland, and the role of wound sepsis in unmasking rheumatic syndromes during the war in Rumania.

In addition to the scientific programme much official hospitality was arranged by the Danish Rheumatism Association, of which Prof. Jarlov is president. The lavish private hospitalities which supplemented this was an atavistic experience enjoyed to the full by delegates from "austerity" areas.

## MEDICAL LIBRARIANS

At a meeting in London on Oct. 4 a new subsection of the Library Association devoted to the professional interests of medical librarians was inaugurated. Various projects which will advance the usefulness and efficiency of medical libraries throughout the country were discussed, some of which will shortly be started. These include a union list of medical serials and their location in British libraries, inter-library loans, and the exchange of material to assist the completion of imperfect sets of important journals. The committees and governing bodies of medical libraries will doubtless welcome the opportunity which will now be afforded of obtaining authoritative advice and assistance from this new professional group. It is of interest to record that Sir William Osler suggested the formation of such a body as long ago as July 28, 1909, at the Annual Representative Meeting of the British Medical Association at Belfast; his suggestion did not then bear fruit, but we hope that success will attend this new venture.

At future meetings papers of a technical and bibliographical nature will be read, and members of the medical profession will always be welcomed as guests. Further details may be obtained from the secretary of the group. The following committee was appointed to manage its affairs: C. C. Barnard (London School of Hygiene and Tropical Medicine); W. J. Bishop (Wellcome Historical Medical Museum); W. A. Lee (Liverpool Medical Institution); W. R. Le Fanu (Royal College of Surgeons); T. J. Shields (British Medical Association); Miss E. Wigmore (National Institute for Medical Research); G. F. Wilson (Manchester Medical Society).

## Reports of Societies

## THE CHARTERED SOCIETY OF PHYSIOTHERAPY

The Annual Congress of the Chartered Society of Physiotherapy was held in Edinburgh on Sept. 25-28 under the chairmanship of Dr. W. S. C. COPEMAN by invitation of the Edinburgh branch of the Society. In addition to a considerable attendance of medical men, 500 members were present.

Prof. J. R. LEARMONTH gave the inaugural lecture on "Arterial Supply and Function in the Extremities." Miss Gertrude Hertzfeld was in the chair. The lecturer summarized the present knowledge of the peripheral vascular system and described its application to medicine and the part that surgery can play. He described his experiments on the reflex effect of heat applied at distal portions of the body and suggested these might ultimately affect the practice of physical medicine. This was illustrated by slides and a film. Prof. R. J. KELLAR then spoke on "Physiotherapy in Relation to Gynaecology and Obstetrics." During the afternoon session Dr. ANTHONY RITCHIE spoke on the experimental side of electrotherapy in somewhat iconoclastic vein, and suggested that many of the hitherto established tenets of electrotherapy are due for revision in the light of modern physics. Dr. DAVID YELLOWLEES followed with an address on the psychological aspect of physical disorders.

The Founders lecture was delivered on Saturday morning on "Mind and Body," by Mr. W. J. STUART (in the absence of Prof. F. A. E. Crew). The chairman was Lord Horder, the President of the Society. The final lectures were by Prof. CHARLES CAMERON on "The Physiotherapist and the Treatment of Tuberculosis" and by Prof. R. W. B. ELLIS on the modern status of the poliomyelitis problem, principally as it affects children. He felt unable to support the Kenny method of treatment fully, although he considered that it had drawn attention to a subject that was previously somewhat neglected. He also warned delegates against placing their faith in convalescent serum for this disease.

Visits were arranged on each afternoon to the Pollock Institute of the University of Edinburgh, the Astley Ainslie Convalescent Hospital, the Simpson Maternity Department of the Royal Infirmary, and the Princess Margaret Rose Hospital for Crippled Children. The Congress was honoured by the Lord Provost, who gave a reception.

## Preparations and Appliances

A NEW AID FOR PHOTOMICROGRAPHY AND  
GENERAL LABORATORY PHOTOGRAPHY

Dr. A. C. LENDRUM, of the department of pathology University and Western Infirmary, Glasgow, writes: The grainless photographic emulsions evolved for microcopying and now available in the larger sizes, provide a valuable new tool for the photomicrographer and laboratory worker. This type of emulsion, which allows a remarkable degree of grain-free enlargement, is of high contrast; but, as Tritton (*Brit. J. Photography*, 1946, 93, 374) observes, this steep contrast can be flattened as desired by modifying the developer, thus offering two distinct advantages. First, with this material alone (e.g. Ilford panchrom line flat film) one is equipped to reproduce anything from the steepest contrast to the softest gradation. Secondly, the grain-free nature of the emulsion allows one to print enlargements of so-called "contact quality." The slowness of this stock is of no disadvantage in photographing the inanimate.

Tritton advises the following dilutions as giving gradations or the negative corresponding to the range of tones in the object named. For the copying of photographs or printed half-tone illustrations use A; for lower contrast (e.g., in the photography of solid objects with their longer range), use B.

## Kodak Ilford

A:	One part	DK.20 or 1D-48	with 4 parts water for	5½ mins. at 65° F.
or	"	"	D.76 " 1D-11	" 5 " " " 5½ " " "
B:	"	"	DK.20 " 1D-48	" 9 " " " 10-13 " " "
or	"	"	D.76 " 1D-11	" 9 " " " 6-8 " " "

In photomicrography, too many workers who are skilled in the use of a single type of emulsion fail to employ a more or a less "contrasty" emulsion for the section that in fact demands it. Admittedly some meet this situation fairly well by altering the colour of the taking light, but this is often really an abuse of the filters and produces an undesirable shift of emphasis in the opacities of the different tissues. It is not always easy to judge the tone range of a section as seen on the ground-glass screen, but a trial negative will show if higher or lower contrast is desirable. Undiluted 1D-11 for 5½ minutes at 65° F. (18.3° C.) gives about as high contrast as is likely to be needed in photomicrography if one intends to enlarge.

Any advocacy of enlarging from photomicrographic negatives is usually met with dark hints about the utility and wickedness of empty magnification, and until now it has not been easy to obtain visually satisfactory enlargements from quarter-plate negatives. An unfortunate result of the techniques available in the past has been the frequent use of the 2-in. (5-cm.) circular print; the critical worker insisted that anything bigger than this showed obvious lack of definition. For most observers, however, this is too small a picture, and if the magnification be under fifty times in order to show the architecture of a tissue, then the cellular detail is quite beyond the middle-aged eye. It is to be hoped that, when conditions permit, editors will accept, as they have to some extent in America, the desirability of larger reproductions. Using this new emulsion one can enlarge from the critically focused central part of the negative, with the further benefit that one obtains the greater depth of focus of the longer focal-length objective. One is thereby not confined to the circular shape which, so long as we have rectangular journals, is extremely wasteful. The surface coating ("bloom-ing") of the enlarging lens is another modern aid to the production of the technically satisfying print.

There is an old saying that the negative must be judged by the print, but the intrinsic virtue of this new film is strikingly shown by comparing with a lens (eight times magnification) a quarter-plate negative on this and on an ordinary emulsion: with the ordinary emulsion resolution of detail tends to be lost in grain, whereas the new emulsion reveals unsuspected and perfectly defined detail.

## Correspondence

### R.M.B.F. Christmas Appeal

SIR,—Christmas comes but once a year, and when it comes should bring good cheer. I therefore appeal to your readers to help those who have to look to others for whatever extra comforts may come their way. The beneficiaries of the Royal Medical Benevolent Fund are either aged or infirm practitioners, their wives, widows, or children; and, but for the grace of God, any one of us or our families might be in like need.

I hope subscribers to the Fund will send an extra donation to make this Christmas a little less bleak and grim. I earnestly ask those who are not subscribers to show their sympathy for their less fortunate colleagues, not only by sending Christmas gifts, but by becoming regular supporters of the Fund.

Contributions and subscriptions should be sent to the Secretary of the Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S.W.15, and marked "Christmas Gifts."—I am, etc.,

ALFRED WEBB-JOHNSON,  
President,  
Royal Medical Benevolent Fund.

### Poliomyelitis

SIR,—I was interested in the letter from Dr. J. M. Alston (Sept. 13, p. 432) calling attention to the evidence suggesting that infection by poliomyelitis virus is common, with paralysis occurring in only a small proportion of those infected. Investigation of another neurotropic virus, that causing louping-ill in sheep; has emphasized to me the importance of factors which in the individual animal allow a potentially neurotropic virus to invade the nervous system from the blood.

Injected directly into the brains of non-immune mice and sheep, louping-ill virus always causes fatal encephalitis. Injected peripherally (intraperitoneally or subcutaneously), it multiplies and reaches the blood, but in only a proportion of animals does it subsequently invade the brain. There is evidence that environmental conditions affecting nutrition determine the proportion of sheep which develop encephalitis. In two experiments carried out in June and July of successive years a group of four and a group of three sheep were inoculated subcutaneously with virus, and none developed encephalitis. Of 27 sheep similarly inoculated during winter and early spring 55% died.

It has been shown that the virulence of louping-ill virus and some other encephalitic viruses can be modified by culture in the developing chick embryo or in tissue culture. Although virus thus modified retains unaltered its ability to produce encephalitis after intracerebral inoculation, it progressively becomes less capable of invading the brain after peripheral inoculation. A strain of louping-ill virus attenuated in this way, so that normally not more than 10% of sheep inoculated subcutaneously developed encephalitis, proved capable of killing nearly 50% of sheep when the inoculations were made during severe weather of last winter.

These observations call attention to the importance of the mechanism ("the blood-brain barrier") which tends to prevent spread of virus from the blood into the brain. They suggest that in these neurotropic infections one must study not only the virus but the factors which influence this spread in the individual animal under different environmental and nutritional conditions.—I am, etc.,

Frant, Kent.

D. G. ff. EDWARD.

SIR,—I was most interested to read the letter on this subject from Dr. E. C. H. Huddy (Sept. 20, p. 468). While in India in 1944 I was medical officer to an officers' training school where we had 500 British and Indian cadets continuously in training. These cadets messed in six separate messes, which I supervised as regards cleanliness and administration, assisted by a most precise non-medical lieutenant.

We had a sudden outbreak among newly arrived British cadets of poliomyelitis. We had six cases in all, of which two died in iron lungs and four recovered with varying degrees of

disability. On the assumption that intestinal infection spread the disease I ordered all eating and drinking utensils to be soaked in chlorine baths for some hours before re-use, and following the implementing of this order the spread of infection ceased. It was significant that the ordinary British Tommy (of whom there were several hundreds in the station), using his own individual eating and drinking utensils, was not affected at all by the outbreak, which was confined to the British cadet messes, where eating and drinking utensils were used communally. The fact that the last two cases occurred 17 days after the commencement of the outbreak suggests infection before the institution of the precautions described.—I am, etc.,

Burton-on-Trent.

J. R. SALMOND.

### Disseminated Sclerosis and Poliomyelitis

SIR,—Your annotation entitled "On the Track of Disseminated Sclerosis" (Sept. 20, p. 460) was of very great interest to me, and I write because I think I can make a useful contribution to the discussion. I am familiar with the experimental work done on swayback in the Peak district under the auspices of the Derbyshire Agricultural Committee, with the help of Dr. Innes. It was thought that the problem had been solved by giving the ewes long before the birth of their lambs salt blocks containing copper to lick. Undoubtedly this treatment considerably reduced the number of cases, but anyone visiting these sheep farms and talking to the shepherds and farmers would soon be convinced that we have still a long way to go.

I think it may be admitted that the element copper is essential to the conduction of nerve energy, and when it is absent in those nerves supplying muscles we get paralysis and changes in the nerve leading to degeneration and demyelination. A copper deficiency in the soil would no doubt predispose to the paralytic condition, but the point that has been overlooked is that copper may be abundantly present, but supplanted in the nerve tissue by some other mineral.

In 1938 I made a determined effort to find the cause of fowl paralysis, and, profiting by the results obtained in swayback, I put great faith in copper. For several years the mortality from this disease had been very high, and the complaint was invariably fatal, although the bird might live for a few weeks. I determined to try one mineral after another in dilute solution injected daily into the crop. The bird was artificially fed as well. I began with a typical and unmistakable case of fowl paralysis. When copper solution had been injected for a fortnight without the slightest benefit, my assistant said: "Don't you think, sir, we have tried copper long enough? May I go on to the next mineral?" I explained I was loath to abandon copper because it was the substance from which I expected most benefit. I said: "Go on to No. 2, but continue with copper as well." The next on the list was cobalt, and the third was nickel, neither of which we had in the laboratory, but we had manganese, which we used. The bird had not had this combination of copper and manganese for more than two days before a remarkable effect was produced. It could stand up and peck. In a few days it had the appearance of a healthy bird. Its comb became red and it started to lay, giving me an egg nearly every day. We had cured fowl paralysis, but my poultry friends who had watched the experiment could not believe it. They reasoned: "As fowl paralysis is an incurable disease there must have been a mistake in the diagnosis." My reply was: "If my theory is correct I can bring back the fowl paralysis." Accordingly I administered a solution of zinc sulphate, and in two days the bird was again on its side, unable to stand. I did not attempt a second cure, but killed the bird and sent the corpse to Weybridge Research Station for a report. The answer soon came: "Advanced fowl paralysis." Since that time I have treated 28 cases, and nearly half of the number have been completely cured. In half of the failures the post-mortem revealed that some other disease was present; and in the remainder probably treatment had not been started early enough. Copper by itself was ineffectual and so was manganese. It required the combination. Probably the manganese acts as a catalyst.

The conclusion I reached was that fowl paralysis is a disease in which copper in some of the nerves is displaced by another metal, usually zinc, derived from the galvanized poultry utensils so commonly used, or from lead which is present in the flint stone used as a powder in the mash, and as grit. Referring

once more to swayback, I have ascertained that the soil in the Peak district where swayback is prevalent is heavily charged with lead. Is it possible that the present outbreak of infantile paralysis has a copper displacement factor in its aetiology? One mineral has been used to an extraordinary extent during the war years and since. I refer to tin. Aluminium cooking vessels were difficult to get during the war years, but since the shops have been flooded with them. Might I suggest that in each case of infantile paralysis the urine should be tested for traces of tin and aluminium?—I am, etc.,

Kenwood, Chesterfield.

J. A. GOODFELLOW.

### Miliary Appearances in the Lungs in Mitral Stenosis

SIR,—I was most interested to read Dr. T. E. Gumpert's article (Sept. 27, p. 488) on "Miliary Appearances in the Lungs in Mitral Stenosis." In the past year I have noted three such cases. Two of these cases had had mitral stenosis of long standing. The miliary appearances in the lungs were seen shortly before death from congestive cardiac failure.

The third case was rather different. The patient, a woman aged 36 years, was admitted to hospital in an extremely collapsed condition with cyanosis, orthopnoea, marked tachycardia, pyrexia, venous distension in the neck, and widespread adventitious sounds in the lungs. She had a previous history of rheumatic fever. X-ray examination of the chest showed widespread miliary appearances very similar to those seen in miliary tuberculosis. Her pyrexia was intermittent in type and proved resistant to penicillin and sulphathiazole in full doses. She had no sputum.

After four days she was put on full doses of salicylate. Her temperature subsided rapidly and her tachycardia became less marked. As it did, a well-marked mitral stenosis was discovered. She remained afebrile though the tachycardia tended to persist. X-ray examination of her chest 14 days after the first film showed the lung fields almost clear. Although she remained afebrile her convalescence was protracted, with marked tachycardia on the least exertion. She had no peripheral manifestations of rheumatic fever.

I should very much like to hear Dr. Gumpert's views on this case.—I am, etc.,

Dublin.

HALDANE G. NELSON.

SIR,—I read Dr. T. E. Gumpert's interesting article (Sept. 27, p. 488) on "Miliary Appearances in the Lungs in Mitral Stenosis," but do not agree with the pathological interpretation or the radiological findings. The haemosiderin-laden histiocytes from the alveoli are motile and travel to the intralobular collections of lymphoid tissue. Here fibrous tissue reaction results in the formation of pseudo-tubercles, at first microscopic, but later increase in the amount and maturity of the fibrous tissue gives the appearances of nodulations apparent in the photograph. The rosette-like appearance he describes in the magnified photograph I should interpret as hyaline degeneration in the centre of the fibrous nodule, which is more opaque to the x rays than the young fibrous tissue at its periphery. The pathology is in fact extra-acinar. The diffuse haziness in the later photograph suggests interstitial fibrosis—i.e., in the inter-alveolar and interlobular lymphatics—seen in Whitehaven in the lungs of haematite miners from Egremont. I think if a photograph were taken now of this patient it would show the same pattern as that seen in 1946.—I am, etc.,

Belfast.

MURIEL O'DOHERTY.

### Early Diagnosis of Tuberculous Meningitis

SIR,—Dr. M. C. Wilkinson's call to the profession (Sept. 27, p. 507) for early diagnosis of hitherto incurable tuberculous conditions will be welcomed by all tuberculosis workers. While there is little one could add to Dr. Wilkinson's observations, I would like to call attention to a recent work which had purely academic significance at the time of its publication, namely, that by biopsy typical miliary tubercles may be demonstrated in the bone marrow in some cases, without any changes in the C.S.F. and before radiological evidence of pulmonary invasion.—I am, etc.,

Colchester.

FRANCIS KELLERMAN.

### Fungus Poisoning

SIR,—The article by Mr. J. Ramsbottom (Aug. 23, p. 304), the annotation (p. 302), and the letters by Dr. C. Allan Birch (Aug. 30, p. 348) and Dr. A. T. Todd (Sept. 6, p. 395) deal with mushroom poisoning, making reference to *Amanita phalloides*. I have had occasion to observe two families poisoned by this mushroom, the full details of which I published in the *Revista Clínica Española* (1945, 17, 211). Pathologically the most striking things to be found were: intense fatty degeneration in the liver with bands of total necrosis and haemorrhagic infiltration; in the suprarenal capsules turbid degeneration in the cellules of the second and third zones of the cortex.

In diagnosis the late onset of the symptoms, almost without exception ten to twelve hours after ingestion, is of great value. The treatment of Limousin (fresh rabbit's stomach and brains) broke down in my cases, as did the intravenous glucose in large doses of Binct. and the draughts of a saturated salt solution of Le Calve, and likewise all the cardiac tonics. I was not able to give the "antiphalloid" serum treatment of Dujarric de la Rivière. My impression is that many of the cases reported as successful through various treatments are caused by other mushrooms, different from the *Amanita phalloides*, the intoxication of which I consider to be almost always fatal. I think transfusions of plasma ought to be tried.

Of the nine individuals under my observation eight died; the only survivor was a woman who had been pregnant for five months, and whose pregnancy went on successfully to its conclusion. This I believe was due to the fact that vomiting began before the others (in shortly under eight hours). In any case it would be interesting to investigate whether pregnancy embraces a state refractory to the amanita toxin, and why.—I am, etc.,

Soria, Spain.

J. CALVO MELENDRO.

### Treatment of Injuries following Insertion of Gastroscope

SIR,—Drs. C. M. Fletcher and F. Avery Jones (Sept. 29, 1945, p. 421) discussed the risks involved in using the flexible gastro-scope. This article brings to my mind the treatment of oesophageal injuries from the gastro-scope practised by me as well as the treatment of inflammatory lesions in the neck region. From 1931 until the beginning of the war I have done many gastroscopies. My results have been very good in the diagnosis of diseases of the stomach. Naturally it is necessary to make an x-ray examination beforehand to be certain there are no pathological changes in the oesophagus, stomach, or neighbouring organs. Marked kypho-scoliosis, a displaced vertebra, or marked aortic sclerosis may make an examination through the oesophagus very dangerous or impossible. One must also bear in mind that the oesophagus of older people is less elastic and more vulnerable to injury. Areas in which generally are found diverticula have a thinner pile of muscles and are easily injured. Introduction of the gastro-scope must be done without pressure. Even so, injuries to the oesophagus and hypopharynx have occurred by experienced physicians, as borne out in the report, by Fletcher and Jones.

In the treatment of such accidents and as well as dangerous anginal septic states—e.g., post-tonsillectomy and so on—the following method used by me has given excellent results. According to the old surgical principle of putting at rest inflamed areas—as, for example, suppuration in the extremity—I apply a padded wire splint to the patient extending over the head, neck, and back, securing it with bandages at the thorax and head and the latter about the forehead, thus preventing any side-to-side or forward-and-backward motion. In this manner all the muscles of the neck and upper parts of the oesophagus will be put at rest. Forbidding the patient from speaking and giving him only liquid food, one has produced the best conditions for localizing the inflammation and its healing. In all my cases within a few days the temperature fell, the inflammation disappeared, and the patients recovered.

This treatment is not only suitable for injuries following the gastro-scope introduction but excellent results by me have also been obtained for all other inflammations in the neck region. The following case was very characteristic: A tonsillectomy performed by a specialist was followed by a septic state lasting five weeks, with fever between 38° and 39.5° C. (100.4° and 103.2° F.), greatly swollen glands of the neck, and a bad general state of

# Protein-replacement therapy

## HEPOVITE

### COMPOSITION (Each 30 grammes contains)

"Protein" (N x 6.25)	15 grm.
Carbohydrate (Maltose)	11.4 grm
Vitamin A	500 i.u.
Vitamin D	50 i.u.
Aneurine HCl	1.0 mg
Riboflavin	2.0 mg
Nicotinic Acid	6.5 mg
Pantothenic acid	11.3 mg
Pyridoxine	0.32 mg
Biotin	0.065 mg
Folic acid	0.05 mg
Inositol	8.1 mg
Choline, Calcium, Phosphorus and Iron are also present.	

A dry granular preparation of malt and enzyme-hydrolysed liver protein, rich in natural vitamins and essential amino-acids.

### DOSAGE

$\frac{1}{4}$  oz. (7 grms) three times daily is sufficient to provide the necessary protein supplement. Hepovite can be taken on a spoon, sprinkled on food or dissolved in milk, fruit-juices or soda-water.

### INDICATIONS

To restore and maintain the nitrogen balance in the presence of tissue destruction and repair, e.g. burns, injuries and post-operative states. To provide a dietary supplement in all cases of nutritional deficiency, pregnancy, peptic ulcer, ulcerative colitis and the toxæmias of pregnancy.

Containers of 5 oz. Price and further details on application to Home Medical Department, Speke, Liverpool, 19, or 50 Bartholomew Close, London, E.C.1.

Made in England by  
**EVANS MEDICAL SUPPLIES LTD**  
Liverpool and London

### IMPORTANT ANNOUNCEMENT

Many years of successful Clinical Practice have proved the trustworthiness of THE ORIGINAL PRODUCT

## NATIVELLE'S DIGITALINE

### AGAIN AVAILABLE

Standard works on cardiology and current medical literature contain many references to its unfailing reliability and constant activity.

Supplied in the following stable forms:—

TABLETS (Pink)	0.1 mgm. = $\frac{1}{10}$ gr.
TABLETS (White)	0.25 mgm. = $\frac{1}{20}$ gr.
SOLUTION 1 IN 1000	(1 mgm. = $\frac{1}{60}$ gr. = 50 drops)
AMPOULES	0.25 mgm. = $\frac{1}{20}$ gr. for intramuscular injection
	0.20 mgm. = $\frac{1}{25}$ gr. for intravenous injection

Samples and detailed literature on request to:—  
**LABORATORY NATIVELLE, LTD.,**  
74-77, White Lion Street, London, N.1.

## The Control of Scabies with 'TETMOSOL'

brand

### TETRAETHYLTHIURAM MONOSULPHIDE

'Tetmosol' is a powerful sarcopticide, and in the forms of 'Tetmosol' Soap and 'Tetmosol' Solution has proved highly effective in both the prophylaxis and treatment of scabies. The Solution (25%), diluted with water before use, provides a most satisfactory and certain method of treatment. It produces a rapid cure of scabies and has the advantage that its application is painless and rarely gives rise to dermatitis.

'Tetmosol' Soap — a pleasantly perfumed soap tablet containing 5% tetraethylthiuram monosulphide — is primarily intended for prophylactic use against scabies. It has proved especially valuable for controlling outbreaks of the disease in families and in communities such as asylums, hospitals, schools, etc. The method of use is simple and convenient so that the co-operation of the scabies patient is readily secured.

'Tetmosol' Solution (25%): Bottles of 100 c.c., 250 c.c. and 2 litres. 'Tetmosol' Soap (5%): Single 3 oz. tablets and boxes of 36.

Literature supplied on request.

ALDERLEY EDGE, MANCHESTER

Ph. 1874

modified. The objection regarding education would not arise if amblyopic eyes were treated before serious schooling began, the ideal being before 6 years of age. Unfortunately many children are not brought until later, sometimes not until young adult life, and at this stage the recognition of the existence of three types of amblyopia is a guide to the value of treatment and will avoid useless occlusion and unnecessary nerve strain.

The three types of amblyopia are:

(1) The "purposive" amblyopia associated with concomitant squint, which may be regarded as a deliberate act of suppression designed to avoid the psychic trauma of diplopia.

(2) The "passive" amblyopia resulting from failure to condition in infancy the central pathways subserving macular perception. This form is a legacy of some condition which interfered during the first two years of life with the visual acuity necessary to educate macular function—uncorrected refractive errors, congenital cataracts, infantile keratitis, ophthalmia neonatorum, etc.

(3) "Pseudo" amblyopia in which, despite a fundus of normal appearance, developmental defects such as macular dysplasia, or acquired defects such as macular haemorrhages at birth, have made central vision impossible. These conditions are frequently termed "congenital" amblyopia and by orthoptists "intractable" amblyopia, but actually are not examples of true amblyopia.

These three types can usually be differentiated clinically, and distress to the child can be avoided if their varying response to treatment by occlusion is borne in mind.

Passive amblyopia is most satisfactory to treat, even in adult life, for there is no active desire to suppress and vision rapidly improves. Treatment of the defective vision due to pseudo-amblyopia is useless and occlusion should be stopped directly the condition is recognized. It is unfair to a child to force it to depend on an eye which is often anatomically incapable of acquiring even central fixation. The value of treatment by occlusion for purposive amblyopia lies between these two extremes. One is fighting the child's active desire to avoid binocular vision, and each case must be considered on its merits, having regard to the fact that the treatment of the amblyopia is only part of the general plan of treatment for the associated squint. In general, occlusion should be used as a routine up to the age of 12 years and tried in a tentative way after that age.

Dr. Moodie has rightly stressed the importance of not subjecting a child with amblyopia to unnecessary nerve strain, but he must recognize the equal importance of securing where possible some vision for an amblyopic eye. It is the first step towards securing the benefits of binocular vision, and, even more, it may be the means of averting the tragedy of blindness later in life should the vision of the other eye be lost from accident or disease.—I am, etc.,

Southsea, Hants.

W. HEDLEY SUMMERSKILL.

### Retained Placenta

SIR.—Some months ago, and again recently, you published correspondence about retained placenta. On neither occasion was a method mentioned which I have used for the last five years. It was first described to me by A. W. Andison, now of Winnipeg, and is mentioned in the Annual Report of the Liverpool Maternity Hospital for 1941. Who originated the method I have been unable to discover. I suspect it is so old that no one knows. When a mare "holds her cleanings" it is the practice in some farming communities to attach a piece of lead piping to the cord and to allow the animal to walk about at will. I do not use lead piping; the method as modified by me is to attach to the cord, by means of a length of bandage, a weight of 2 lb. (0.9 kg.). After a few minutes to allow for stretching of the cord the bandage is marked in ink where it passes over the end of the bed. In many cases, after a variable interval, the mark will be found 4–6 in. (10–15 cm.) lower than this, indicating that the placenta is now awaiting expression from the lower segment and upper vagina.

This is an "over the telephone" method. It can be used in desperate cases while the blood loss is being made good by transfusion. It can be used in cases where the general condition has not deteriorated. If the patient is fit but is bleeding, more immediate treatment, either by manual removal or intravenous ergometrine, is to be preferred. The obvious danger of this method is theoretical only. I refer, of course, to inversion of the uterus. The traction is not sufficiently strong to bring about this catastrophe. I suggest that the mechanism by which a

successful result is obtained is that the empty lower segment is folded upon itself in a concertina-like manner. Stimulation of the lower segment in this way causes the upper segment to contract and expel the placenta. If the placenta has partly occupied the lower segment, as is often the case when it is retained, this concertina effect should, and in fact does, stop bleeding from the area of detachment.

However the result is produced, it is extremely gratifying to find, after waiting possibly for hours for blood transfusion to render a patient fit for manual removal, that this hazardous procedure is not required. The descent of the mark on the bandage indicates that gentle fundal pressure is all that is necessary. For recording purposes I have called this method "continuous light cord traction."—I am, etc.,

Stockport, Cheshire.

WALTER CALVERT.

### Planning and World Population

SIR.—In his letter (Sept. 6, p. 395) on this subject Dr. E. F. Griffith states: "Now that modern contraceptive methods are so reliable and comparatively cheap, it should be possible, by means of a well-thought-out education policy, to bring a knowledge of these matters to the women of the East." It would be just as logical to state: "Now that motor banditry is so reliable and comparatively safe (vide records of undetected crime), it should be possible, by means of newspaper reports and cinema films and other methods, to bring a knowledge of these matters to the men of the East," because both practices are intrinsically evil—i.e., in the acts themselves and not merely on account of their consequences.

One of man's functions as made known to him by his reason is the continuance of the race, and contraception, by frustrating this function, although using the physical act of sexual intercourse, thereby becomes intrinsically evil, and this applies to each individual contraceptive act.—I am, etc.,

London, W.C.1.

G. E. PAUL.

### Contact Lenses

SIR.—As a recent convert to the wearing of Hamblin-Dallos contact lenses, from my own experience I can scarcely agree less with the remarks of Mr. A. Seymour Philips (Sept. 20, p. 469). The sensation of a foreign body beneath the lids is very soon lost, and I have found that after only a month of systematic and careful conjunctival training I am now able to wear them without embarrassment up to 16 hours, with occasional removal for clearing off epithelial debris and immediate replacement. The secret for complete comfort is the use of a physiological saline eye-bath as part of the daily toilet. As a microscopist these lenses take an invaluable place in my daily work, and the sense of ocular fatigue and lid weariness experienced in my spectacle days is now relegated to past memories.—I am, etc.,

Exeter.

PETER WARREN.

### Salaries of Specialists in N.H.S.

SIR.—I cannot think that any difference of opinion which may have arisen over the payment of psychiatrists as compared with physicians and surgeons is due, as Dr. Northage J. de V. Mather suggests in his letter (Sept. 6, p. 398), to fluctuations in the standard of the D.P.M. as opposed to that of the M.R.C.P. and F.R.C.S. I would almost, with respect, suggest that there exists here either a confusion of thought or even a wishful thinking. Surely the D.P.M. is, with many others, a special diploma—no more and no less than that. The M.R.C.P. and the F.R.C.S. are higher qualifications and rank accordingly; they are difficult to obtain—and rightly so—without considerable postgraduate learning and experience, and the whole background which a successful candidate must possess is a wide one.

In my opinion (which I know is shared by many others) the psychiatrist would do well to aim at attaining, in the realm of medicine, something of the standard demanded by the M.R.C.P. before he embarks seriously upon his chosen specialty. There can hardly be any comparison between the M.R.C.P. and the D.P.M. The latter cannot equal (which appears to be Dr. Mather's suggestion) the former, and never was it meant to do so. If the consulting psychiatrist is to rank as does the consulting physician, he should in my view possess both the higher qualification and the diploma of his own specialty.—I am, etc.,

London, W.1.

MAURICE L. YOUNG.

## The Extent of Neurosis

SIR,—I seem to have been more fortunate than Drs. L. F. Donnan (Sept. 6, p. 396) and H. G. St. M. Rees (Sept. 20, p. 468), as my figures for neuroses (and psychoses) are far less than their estimates. In his book *The Common Neuroses* T. A. Ross stated that investigation over 1,000 consecutive insurance cases showed 33½% were neurotic. It was to verify this figure that I started to keep records. Most of my colleagues would say I was biased towards psychiatry. During my Army service I went into psychiatry, as I felt such knowledge and experience would be invaluable in general practice. I submit all my neuroses to psychotherapy, and a consultant psychiatrist is called in when necessary. The time taken in dealing with psycho-neurotics is very considerable, and they certainly appear more numerous than is actually the case.

My diagnoses were put down under the headings of medical, surgical, obstetrical, and neuropsychiatric. Since Jan. 1, 1947, I have made a total of approximately 9,000 consultations and visits. Of this, 66% were medical, 16% surgical, 5% obstetrical, and 14% neuropsychiatric.

I would stress the point that any assessment of this nature is bound to be very approximate, as there are so many variables. In the first place in any disease there is an upset of both psyche and soma. Even a streptococcal sore throat, so typically somatic, carries with it a certain degree of anxiety. Secondly, the diagnosis of a functional complaint is not as easy, or as readily confirmed by scientific test-tube medicine, as are somatic disorders; and I suggest that, in the present state of our knowledge, if six partners made an estimate of neurosis in the same practice, each would give a different figure. Thirdly, the locality definitely influences the incidence of neurosis. In one isolated row of miners' cottages here most of the women (not the men) are neurotic. Buses are few and far between, shopping is most difficult, and there is no social life. Housework and having babies are the only occupations open to the female population, and many crack under the strain.

On the whole our rural community here is a very fortunate one in these hard times. Gardens, fowls, and the back-yard pig eke out the rations. Half the population are miners and have no fuel difficulties. There are a dozen industries in the district, so that the young people have a reasonable choice of work. Social life could be much better, but sport, dances, and the cinemas do offer scope for leisure hours. Perhaps it is this happy combination of circumstances which makes the figures for this area lower than for most places.—I am, etc.,

Ibstock, Leicester.

C. A. H. WATTS.

SIR,—Dr. D. Yellowlee's letter on the subject of the inadequate treatment of the neurotic (Sept. 20, p. 468) is provocative—no doubt intentionally. When I started in general practice I held views very similar to his on the subject. I have referred as many as possible of these patients to the psychiatrists. So far the results are, roughly: cured, nil; improved, nil. The attitude of the patient on returning from "adequate treatment" is, "Now, after this somewhat mystifying interlude, let's get a bottle of medicine."

I am grateful to the psychiatrists for considerable help in diagnosis, and for taking the patients off my hands, but I am becoming convinced that they are quite as impotent as the G.P. in removing the underlying causes of neurosis.—I am, etc.,

Beaminster, Dorset.

ARTHUR DEARLOVE.

## Dyspepsia and Aspirin

SIR,—Now that the incidence of upper respiratory infections is increasing I feel that it is no coincidence that the number of patients complaining of dyspepsia is also increasing. Proprietary preparations containing acetylsalicylic acid are numerous, and the usual story is, "I've had a cold, Doctor, and it's settled on my stomach." Invariably I find that self-medication with one of the above is the cause of the dyspepsia.

There are few ulcer patients who can tolerate acetylsalicylic acid, and yet year after year so many of them are allowed to suffer winter exacerbations due to failure to warn them of the danger of such drugs. The odd thing is that so few patients discover this for themselves, yet so readily agree when it is pointed out to them. I have a patient in whom even gargling with aspirin is sufficient to cause a relapse owing to the fact that even a few grains are inadvertently swallowed.

Calcium aspirin is not the answer to all patients who wish to treat themselves for a headache or simple cold. So far I have found that phenazone 5–15 gr. (0.32–1 g.) seems to be harmless. Recently, having seen a severe haematemesis in an aspirin-sensitive patient, I feel that it is not too early to advise all dyspeptics to avoid any drug containing acetylsalicylic acid. The characteristic of dyspepsia so caused seems to be its stubbornness in reacting to the usual alkalis. I might end by pointing out that the "stomach trouble" so often complained of by sufferers from migraine frequently has a similar aetiology.—I am, etc.,

St. Helens, Lancs.

JAMES KAY.

## POINTS FROM LETTERS

### Acute Haemolytic Anaemia (Lederer type)

Dr. G. A. D. writes: With reference to Dr. G. Papayannopoulos' communication on the above subject (Sept. 6, p. 371) I write in the hope that my personal experience may help in earlier diagnosis and also to support the infective theory of origin. From Sept. 3, 1939 to Aug. 1, 1945, I had done two doctors' work and was a bit tired but in reasonable health. On Aug. 1, I felt a persistent nausea and abhorrence to food. On Aug. 2, I had to take charge of a cadet camp for 300 which I could not leave and so remained a my post for 10 days. On Aug. 3, I passed dark red urine in the morning. On Aug. 4, I was so breathless I could not walk the length of the field. On Aug. 5, my hands became jaundiced in the palms. On Aug. 7, I thought I heard a gas engine running, but soon realized it was a drumming in my own head. Any exertion caused breathlessness, and gradually my limbs became weaker until Aug. 18, when I consulted a heart specialist, who found tachycardia and advised consulting a haematologist, whom I saw on Aug. 20 who diagnosed Lederer's anaemia. My haemoglobin was then 19%; no megaloblasts, no oedema, and no splenic enlargement were present. During the following week a swinging temperature made me finally take to my bed, and within a week, in spite of liver injections, iron, etc., I became unable to lift my head from the pillow and went to the Bristol Royal Infirmary by ambulance almost unconscious. Following 6 blood transfusions, I gradually made a complete recovery. May I emphasize that the onset, while it appears acute, is not so much sudden as obscure, insidious, and unusual and is not recognized by patient or doctor, as a rule, to be of serious import. In addition, the continual drumming noise in the head renders the patient completely mentally bewildered, causing a definite lack of appreciation of the seriousness of the symptoms or their progressive nature. The nausea, "head noises," dulness of visual and mental perception, the breathlessness and asthenia are so easily confused with nervous exhaustion due to overwork, etc., that it is not until the jaundice, fever, and red urine appear that the diagnosis is made and the life-giving blood transfusions commenced.

### Poliomyelitis

Dr. J. C. JONES (London, S.E.25) writes: May I be permitted to indicate a line for the treatment of infantile paralysis that I used in previous epidemics which appeared to give a very rapid cure from the paralysis if given immediately after the pyrexial stage had ended. . . . As soon as the temperature is flat and the paralysis has happened, the patient is at once put on to full doses of strychnine in relation to the age of the patient. This is given for 24 hours, when the dose is increased to 1 min. (0.06 ml.) above the maximum dose. After the next 24 hours the dose is raised again by 1 min., and so on. . . . My experience was that before the dose got dangerously high there was sufficient improvement for one to be able to form a judgment. My opinion is that one should be prepared to push the dosage if necessary until three times maximum is reached. This presupposes that there are no contraindications and that the patient is kept under close observation. Of this I feel confident, that maximum doses are useless, that the cure is established only on the level of over double maximum dosage. . . .

### Symptoms of Varicose Veins

Dr. A. P. BERTWISTLE (Dumfries) writes: In their excellent article on "Treatment of Varicose Veins" (Sept. 20, p. 452) Prof. A. M. Boyd and Mr. D. J. Robertson rightly stress lack of pain, save when phlebitis is present. They do not, however, mention a somewhat distressing symptom—namely, a sense of weight and dragging; the limb seems to tire with the least exertion.

### Bodies for Dissection

D. M. A. (Birmingham) writes: There is a Cremation Society in existence for those who favour cremation, and I should like to see a "Body Donors" (or some other suitably worded title) Society formed in this country.

## Obituary

### E. ff. CREED, M.A., D.M., F.R.C.P.

Edward ffolliott Creed, who was the second son of the late Rev. E. Creed, died suddenly, on Sept. 27 after a myocardial infarction at the age of 54. He entered Trinity College, Oxford, in 1910 as a Millard Scholar, and took honours in the Final School of Natural Sciences (Chemistry) in 1913. Going on to King's College Hospital Medical School as a Burney Yeo Scholar, he took the B.M. degree in 1916, and served in the R.A.M.C. as a captain, working on malaria problems at Sierra Leone. His early experience and training in scientific laboratory work led him to the pathological department at King's on his return from war service, and he was appointed bacteriologist. On the retirement of Dr. d'Este Emery in 1921 Creed was appointed director of the pathological department, and director of pathological studies in the medical school.

Always keenly interested in the clinical side of pathology, he took the M.R.C.P. in 1923, being elected F.R.C.P. in 1932. He proceeded D.M. in 1927. His disposition was rather quiet and retiring, but in matters which concerned him, his work, or his department he could always state a case with logic and vigour. His shrewd common sense, precise outlook, and retentive memory made him a capital chairman of committees, so that in hospital affairs his advice was always welcomed, and was always the product of sound judgment and balanced consideration. As a teacher the qualities of lucidity and careful preparation were notable in his lectures. Although a hard worker for long hours, he always had time to explain the technical side of any problem and to give useful suggestions as to some line of investigation. To the clinician a chat with Creed about the pathological aspects of some puzzling case was stimulating and instructive. As an examiner his sane judgment made his conclusions fair to the candidates and helpful to his colleagues. His knowledge was wide and his memory excellent, and one rarely turned to him in vain for accurate and helpful information. For young workers in his laboratory it was a privilege to enjoy the time he would always gladly spend on demonstrating a section or explaining a technique. Nothing was too much trouble for Creed in these matters; and I well remember the pains he took in revealing to me the then complex mysteries of the Wassermann reaction twenty-five years ago.

Creed was not a voluminous writer, but his small output was of high quality. Nothing but the very best would satisfy his fastidious standards or reach his level of meticulous accuracy. Here was an excellent example both to the clinician who sought his advice and to the young pathologist learning his trade. Although mainly interested in bacteriology, he was also attracted to haematology, and carried out some ingenious researches on acholuric jaundice. His early training in chemistry gave him a good appreciation of biochemistry and a long experience of necropsies for coroners completed his equipment in morbid anatomy. He was, indeed, an all-round pathologist in a sense that is likely to become rare in the future as specialization divides the subject still more deeply. His colleagues, who were all his friends, will find him hard to replace. Those informal chats in his room, on a hundred and one subjects, always stimulating and instructive, and seasoned by his lively humour, will be sadly missed. All will sympathize with his widow and two daughters.—T. E.

A memorial service for Dr. Creed was held in the Hospital Chapel at Denmark Hill, on Oct. 8.

### H. COURTNEY GAGE, M.R.C.S., L.R.C.P.

Dr. Harold Courtney Gage, director of the radiological department of St. Mary's Hospital since 1935, died in London on Oct. 4, a few days before his sixty-second birthday. Before 1914 Gage worked with Sir James Mackenzie Davidson, one of the pioneer radiologists in this country. He went to France with the Essex Yeomanry, was wounded early in the war, and was invalided out of the Army. Before long he was back in France with the American Red Cross as an x-ray technician, and he was responsible for a great deal of radiographic work

on war casualties; he also assisted at two large French civil hospitals near Paris, and the French Government made him Officier de l'Instruction Publique. He originated a number of techniques for the investigation of spinal injuries and the localization of foreign bodies, which were described in the *Journal de Radiologie* in 1916-18.

Courtney Gage joined St. Mary's Hospital Medical School in 1919 and qualified in 1924. He came to medical radiology with an unrivalled technical experience behind him, and was elected assistant honorary radiologist at St. Mary's Hospital in 1926. He became director of the radiological department in 1935, holding this appointment until his death. He was honorary radiologist to the Hampstead General Hospital from 1925 to 1939, and consulting radiologist to St. Luke's hospital for many years. He served with distinction on the councils of the British Institute of Radiology and of the Section of Radiology of the Royal Society of Medicine. Although invited to become president of both these bodies, he declined since he felt he could not preside effectively because of his deafness, which grew worse about 1934.

He was the honorary editor of the *British Journal of Radiology* from 1940 to 1943, and no one could have given more care and attention to its publication. The Institute made him an Honorary Member, a rarely bestowed honour, in 1943 as a token of appreciation of his devoted work. He was a founder Fellow of the Faculty of Radiologists and the first examiner in diagnostic radiology in the fellowship examination. He also served on the British X Ray and Radium Protection Committee, and was a member of the council of the Medical Defence Union.

During the second world war Gage did as much as any other worker to bring "mass miniature radiography" to a high standard. He gave devoted service to the Norwegian Forces in Britain, and for this work he was created a Knight of the Royal Order of St. Olaf (in the First Class) by King Haakon of Norway. As a radiologist Courtney Gage was held in high esteem by both his clinical and his radiological colleagues; his advice was constantly sought and was always most willingly given. His opinion was always of the greatest practical value, and though his academic knowledge was seldom aired it was indeed profound. As a teacher he gave his time unsparingly to post-graduate students, and many radiologists in this country and in the Dominions, especially in New Zealand, would acknowledge their indebtedness to Gage.

His outstanding characteristics were perhaps his devotion to the service of others, his quiet and determined thoroughness, and his kindness. No one could have been more considerate of the opinions and feelings of others. Away from his professional work Gage was devoted to music. The most successful musical society at St. Mary's Hospital, grew out of the gramophone recitals Gage gave to those on duty during the London air raids. He was also a great authority on photography and a skilled photographic craftsman. Perhaps Gage was happiest of all when he was entertaining a few friends. He was an excellent host and delighted in the preparation and service of a perfect meal. He bore his final illness with resolution and fortitude.

### C. M. BEADNELL, C.B., M.R.C.S., L.R.C.P.

Surgeon Rear-Admiral C. M. Beadnell died at Petersfield, Hants, on Sept. 27, at the age of 75, after a short illness. He was appointed C.B. in 1924, and made honorary physician to H.M. the King a year later.

Charles Marsh Beadnell was born on Feb. 17, 1872, in a military camp at Rawalpindi. The eldest son of Major C. E. Beadnell, R.A., he was educated at Cheltenham College and Guy's Hospital. He qualified in 1895 and entered the Royal Navy in the following year. He volunteered as a surgeon in the American-Filipino war and was landed with American troops on the island of Luzon, where he saw much fighting. In 1899 he was in action with the Naval Brigade in South Africa and was mentioned in dispatches three times. For these services he was awarded eight years' special accelerated promotion to staff surgeon. When H.M.S. *Renown* was conveying the King and Queen of Spain to the Continent in 1907, Charles Beadnell was the medical officer of that ship. He also served in H.M.S. *King Alfred*, the flagship on the China station. He was on active service again as S.M.O., 2nd Cruiser Squadron, in the war of 1914-18. He was for three years the Naval

## OBITUARY

592 OCT. 11, 1947

Member of the Medical Consultative Board of the Admiralty, and from 1923-6 he commanded the R.N. Hospital at Chatham.

Admiral Beadnell was a man of wide and varied interests. As a young man he collected human skulls showing the effects of gun-shot wounds. He wrote papers, pamphlets, and books on such subjects as small-bore projectiles, disposal of casualties in naval warfare, environmental factors afloat, the evolution of scientific and the origin of the kiss. He compiled a dictionary of scientific terms and an encyclopaedic work on science and war. His special interest in evolution made him a rationalist early in life; indeed, before he left Guy's Hospital he confessed that he was "a devout agnostic." His views, of course, were not universally acceptable, but his sincerity and tolerance often disarmed criticism. He had been a member of the British Medical Association for over fifty years, and for many years past he had been one of our most constant correspondents. The last letter of his to appear in the *Journal* was published as recently as Sept. 13. After his retirement Admiral Beadnell became a director of the Rationalist Press Association, and later its president. He married Ellen Louisa, daughter of George Bailey, of Gloucester, who survives him.

Dr. EDWARD GEORGE PERODEAU died at the age of 81 at his home in Twickenham on Aug. 22. Dr. Perodeau was a student at University College Hospital, and he graduated in 1904, proceeding M.D. in 1912. He was for a time clinical assistant at the ear and throat department of the Royal Northern Hospital. Since 1914 he had acted as medical officer to the Metropolitan Water Board, and he had been associated for nearly forty years with St. John's Hospital, Twickenham, as consulting physician and latterly as chairman of the medical staff. Dr. Perodeau had been a member of the British Medical Association for over forty years and was chairman of the South Middlesex Division in 1922. He was seeing patients up to the day before his death, and only a week previously had spent a few days in his caravan trailer on Box Hill. He was one of the oldest members of the Camping Club of Great Britain.

Dr. JAMES YORK MOORE died at Worthing on Sept. 10 at the age of 56. Dr. Moore, who was a student of Guy's Hospital, qualified in 1913 and was in general practice near Sawston, Cambridge. During the first world war he served with distinction in France and Gallipoli, and was awarded the O.B.E. After the war he remained in the Service for a short time before settling in general practice in Sawston. In 1939 he rejoined the R.A.M.C. and went to France where he served as A.D.M.S. for the Surrey and Sussex areas. He reached the rank of colonel, but was invalided in 1945, when he developed progressive muscular atrophy. Although considerably handicapped he returned to practice, but his condition deteriorated so rapidly that he had to retire at the end of 1946.

Dr. L. A. Parry writes: I first met Colonel York Moore during the last war when he was A.D.M.S. stationed at Hayward's Heath and I was liaison officer between, first, the Canadian Army stationed in Sussex and, later, the 21st Army group and the E.M.S. We came frequently and intimately in contact. During our many meetings, both at Hayward's Heath and at the various hospitals throughout Sussex which we visited together, I was struck by his invariable good temper and his admirable method of carrying on his duties and work, his tactfulness, his care of, kindness to, and thought for, his patients. He saw in hospital, and his general sturdy way of doing his work and his duty in such a satisfactory way under such great strain. All of us who came in contact with him will remember him as the soul of kindness. We all valued him as a man well worth knowing and working with. We regret very deeply the passing of a beloved friend.

J. D. S. writes: York Moore was really a fine country general practitioner. He was intensely interested in all branches of medicine and always kept abreast of modern developments. A deeply religious and philanthropic man, he was always ready to help with any activity in his village community. The "Ox-Road" which he organized is well remembered to-day. He was secretary of Cambridgeshire Insurance Committee for many years, and during his last year of practice he entertained his colleagues as president of the Cambridgeshire and Huntingdonshire Branch of the B.M.A. His many friends both within and outside the profession and his village of Sawston will miss him sadly. He leaves a widow, a son who is also qualified and serving in the R.A.F., and two daughters who are nursing.

C. F. S. writes: No reference to the late Mr. Ernest Miles would be adequate without special mention of that masterpiece of surgery, the abdomino-perineal excision of carcinoma of the rectum. It is not too much to say that there are many thousands of people to-day enjoying good health, able to work and lead an ordinary life, who not so long ago would have been condemned to a miserable, painful, and lingering death. Not only did he himself bring the technique of the operation to a high degree of perfection but he was always only too glad to teach others; no young surgeon ever went away from seeing him without some friendly advice and encouragement. Although Miles's work was widely known and appreciated abroad, especially in the United States and Canada, I feel that it never received the recognition it should have done in his own country. Perhaps it is not generally realized that he was essentially a shy man and quite incapable of seeking the limelight. His large and extensive practice was due not only to his outstanding skill and ability but also to his natural courtesy and kindness of manner and to the unremitting care and attention he gave to all his patients, whether in hospital or in private practice.

## Medico-Legal

DESERTION BY THE FEEBLE-MINDED  
(FROM OUR MEDICO-LEGAL CORRESPONDENT)

The case of *Brown v. Brown*<sup>1</sup> illustrates the bewildering difference of outlook which occasionally shows itself between the legal and the medical mind, especially in mental matters. A woman deserted her husband in March, 1938, and in the following October she was charged before magistrates with stealing. Found on medical examination to be feeble-minded, was certified for over three years, but the wife's advisers answered that, as a husband petitioned for divorce on the ground of her desertion for over three years, but the wife's advisers answered that, as a certified mental defective, she could not be considered capable of forming an intention to continue the desertion. They pointed to the earlier case of *Williams v. Williams*,<sup>2</sup> in which the Court of Appeal had held that a person certified of unsound mind must be regarded as incapable of forming the intention to desert or return, and that evidence of his actual state of mind is inadmissible. The President of the Divorce Division, Lord Merriman, would not accept this analogy, but held that the wife was capable of forming the necessary intention and granting the husband a decree of divorce. In doing so he came to a decision with which no reasonable person will quarrel, but the grounds on which he reached it are enough to drive a medical mind to despair.

Lord Merriman said that under the Lunacy Act, 1890 lunatic is defined as "an idiot or person of unsound mind," the Mental Treatment Act, 1930, the word "lunatic" is replaced by "person (or patient) of unsound mind." Meanwhile the Mental Deficiency Act, 1913, amended by the Act of 1927, with idiots as the lowest of four classes of mental defectives, which the definitions are framed on a diminishing scale, other three being imbeciles, feeble-minded persons, and imbeciles. Therefore, said the President, a feeble-minded person is three statutory removes from a person of unsound mind, and, though a person who is certified as of unsound mind cannot form an intention to desert, no such presumption need attach to one who "is not of unsound mind but is merely a mental defective and in the third category of such persons . . . three degrees lower in the scale of mental illness."

With the greatest respect to the learned President, this assessment of volition by categories, beginning with the certified through idiots and imbeciles to moral defectives, though doubtless correct in law, bears little relation to reality. Volition can be assessed only by examining the individual patient. The law already does this when a certified mental patient is accused of a crime, and when one has made a will. That it should not do so in divorce matters is an anomaly.

<sup>2</sup> 1939 3 All E.R. 315.

# CALCIUM ABSORPTION

THE intestinal absorption of Calcium is subject to many variable factors, and in prescribing additional calcium during pregnancy or lactation, during the years of rapid skeletal growth, or as a prophylactic against circulatory disorders it is essential to select a preparation the composition of which is based on a study of the mechanism of calcium absorption. In this connection we would commend for your attention

## 'CALOGEN'

TABLETS CONTAINING

Vitamin D	500 I.U.
Calcium gluconate	4.84 gr.
Calcium glycerophosphate	1.93 gr.
Calcium hypophosphite	0.97 gr.
Manganese glycerophosphate	0.2 gr.
Cobalt glycerophosphate	trace

'Calogen' is scientifically formulated to produce the maximum absorption and utilization of calcium, and the ingredients are presented in a pleasant lemon flavoured tablet, which is acceptable to children and adults alike.

Issued in bottles of 60, 250 and 1,000 tablets.

Descriptive literature available on request.

GENATOSAN LTD., LOUGHBOROUGH, LEICS.

Telephone: Loughborough 2292

The word 'Calogen' is the registered trade mark of Genatosan Ltd.

M.37

## Vitamin Therapy -its uses and limitations

### GROWTH REQUIREMENTS IN CHILDHOOD

The relatively high metabolic needs of growing children must be met not only by energy-producing foods, but also by the factors needed for their metabolism, namely vitamin B<sub>1</sub> (aneurine) and the co-enzymes of the vitamin B<sub>2</sub> complex. Failure to supply these may be revealed in poor growth, debility, abnormal fatigue. Such a combination is highly suggestive of a deficiency of the factors—vitamins, protein, minerals—so richly supplied by Bemax.

### BEMAX Stabilised cereal embryo

Chemists now receive sufficient Bemax to ensure that all prescriptions are met.

1 oz. of Bemax provides approximately:—vitamin B<sub>1</sub> 0.45 mg.; vitamin B<sub>2</sub> (riboflavine) 0.3 mg.; nicotinic acid 1.7 mg.; vitamin B<sub>6</sub> 0.45 mg.; vitamin E 8.0 mg.; manganese 4.0 mg.; iron 2.7 mg.; copper 0.45 mg.; protein 30%; available carbohydrate 39%; fibre 2%; caloric value 104

## PHENOXYETOL

### THE ANTI-PTYOCYANEA COMPOUND

**H**ERE is an important new bactericide and antiseptic. Phenoxyetol (Nipa) is B-phenoxyethyl-alcohol, specially purified and standardised, for use in medical treatment and for pharmaceutical preparations.

Phenoxyetol is effective against certain gram-negative organisms, including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds... abscesses... indolent ulcers... associated with *Ps. pyocyanea*. It should not be used for parenteral injections.

Phenoxyetol is very effective in pyocyanic infections of burns or superficial wounds. It is especially useful in the preparations of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

## HEAD PESTS

*a NEW  
approach*

SULEO Eradicates and Prevents Head Pest Infestation (*Pediculosis capitis*). One application will clear the most heavily infested head or will keep a clean head free from head pests for 14 days, even if contacts are made with infested persons.

"Every case so far treated with D.D.T. emulsion has been cured by one application. This result is to be expected, as the duration of protection with D.D.T. exceeds the incubation period of the nits." (B.M.J., 24th March, 1945.)

# The Successful Treatment of

## FIBROSITIS

and certain cases of

## RHEUMATISM

with

## NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in many cases, early recovery.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic Origin)."

NOVUTOX is available in:

2-ox and 20-ox. Bottles: 1%, 1% and 2% Solutions.  
Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinatoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

PHARMACEUTICAL MANUFACTURING CO. LTD.

## MYCIL

*A new fungicidal preparation*

A fungicidal substance of a new type has been evolved in the Research Laboratories of The British Drug Houses Ltd.—*p*-chlorophenyl-*a*-glycerol ether. Under the name Mycil, preparations of this substance are now available for the treatment of athlete's foot and associated conditions. *p*-Chlorophenyl-*a*-glycerol ether is an active fungicidal and bactericidal substance of which Mycil ointment contains 0.5 per cent. and Mycil dusting powder 1 per cent. Further details are available on request.

## An Effective Analgesic

WHILE modern chemical research has evolved many and diverse analgesics, the popularity of acetylsalicylic acid and its reputation for effectiveness remain. Nevertheless, some physicians have hesitated to employ it owing to its tendency, in certain conditions, to irritate the stomach.

In "Alasil" however, the desirable therapeutic effects of acetylsalicylic acid are maintained, without the tendency to irritation, by combining the acid with Dibasic Calcium Phosphate and "Alocol" (Colloidal Aluminium Hydroxide), an effective gastric sedative and antacid. Thus "Alasil" helps to solve the problem of administering acetylsalicylic acid in an effective form, even to patients with sensitive stomachs.

The advantages of "Alasil" have been well proved in practice. Experience shows that it can be prescribed with safety to patients of all ages.

Each tablet contains 5 grs. Acetylsalicylic Acid, 6 grs. "Alocol" (Colloidal Aluminium Hydroxide), and 1½ grs. Dibasic Calcium Phosphate.

## Alasil

A supply for clinical trial with full descriptive literature sent free on request.

## SUPREMACY through QUALITY

For many years London Hospital Catgut has provided:

1. Maximum Flexibility. 2. Elasticity which gives necessary expansion under stress. 3. Tensile Strength greater than B.P.C. and U.S.A. Pharmacopoeia requirements.

THE LONDON HOSPITAL CATGUT DEPARTMENT - LONDON - E1 - ENGLAND

## Universities and Colleges

### UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B.—J. H. Blaskey, J. A. Chisholm, Elinor Dubas, D. Hobson, V. H. Morris, J. B. Parkin, D. Rider.

### UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—E. C. Armstrong, P. D. Bedford, M. Braithwaite, M. H. Catverley, J. Dawson, O. G. Jones, J. McKennell, I. G. W. Pickering, E. E. Rawlings, A. H. Rivett, D. E. H. Robertson, W. S. Saffern, R. Varley.

FINAL M.B., Ch.B.—*Part I (Pathology and Bacteriology, Pharmacology):* Z. Briery, E. M. Chippindale, J. W. Daggett, P. H. Daley, N. J. Dowdall, R. England, E. E. Green, C. M. Inebnit, W. K. Shanks, O. J. Sharp, M. C. Simpson. *Part III (Medicine, Surgery, Obstetrics and Gynaecology, Therapeutics):* 121. A. Tolgate, V. A. Bell, M. Benard, R. M. Bowker, K. A. Exley, J. A. Gawthorpe, W. J. Glover, A. E. W. Gregson, J. K. Hardy, B. Jennings, G. A. Kiething, B. G. Peet, J. H. Rust, J. Samuel, B. K. Scott, J. D. Thornton, G. C. Turner, I. M. Vella, J. K. Walker, N. M. Whalley.

<sup>1</sup> With distinction. <sup>2</sup> With first-class honours.

### UNIVERSITY OF DURHAM

The title of Emeritus Professor of Surgery has been conferred on John Hamilton Barclay, M.D., M.S., F.R.C.S., who retired from the Chair in January.

### UNIVERSITY OF EDINBURGH

Prof. N. Hamilton Fairley, M.D., F.R.S., F.R.C.P., Director of Special Research, Hospital for Tropical Diseases, London, will deliver the Cameron Prize Lecture for 1947 in the Anatomy Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, on Friday, Oct. 24, at 5 p.m. His subject is: "Chemotherapy in Malaria." All students and graduates are invited to attend the lecture.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

In view of the Government's decision about dinners, it has been reluctantly decided to cancel dinners of Fellows on the nights before committees. The October dinner, therefore, is cancelled; the possibility of holding dinners will be reconsidered later in the year.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following lectures will be delivered at the College (Lincoln's Inn Fields, W.C.): Thursday, Oct. 16, 3.45 p.m., Surgery Lecture by Prof. John H. Garlock, Surgical Treatment of Carcinoma of the Oesophagus and Upper Stomach; Friday, Oct. 17, 5 p.m., Hunterian Lecture by Prof. Murray A. Faconer, A Study of Principles and Results of Lumbar Intervertebral Disk Surgery; Wednesday, Oct. 22, 5 p.m., Arris and Gale Lecture by Mr. H. F. Lunn, A Contribution to the Anatomy of Inguinal Hernia; Friday, Oct. 24, 5 p.m., Arnott Demonstration by Mr. Lunn, The Pelvis and the Erect Posture; Monday, Oct. 27, 5 p.m., Arnott Demonstration by Mr. Lunn, The Applied Anatomy of Testicular Descent; Tuesday, Oct. 28, 5 p.m., Arnott Demonstration by Mr. Lunn, The Cerebral Cortex and the Status of Man; Wednesday, Oct. 29, 5 p.m., Moynihan Lecture by Mr. W. R. Douglas, Surgical Treatment of Metastatic Carcinoma of the Cervical Glands; Thursday, Oct. 30, 5 p.m., Imperial Cancer Research Fund Lecture by Dr. James Craigie, Viruses, Self-producing Substances and Tumours. The lectures are open to those attending courses in the College and to all other medical practitioners, dentists, and advanced students.

At an extraordinary meeting of the Council of the College, held on Sept. 22, with Sir Alfred Webb-Johnson, Bt., President, in the chair, the Hallett Prize was awarded to Dr. Natalal Jivan Shah (Guy's Hospital).

It was decided that the additional six months' period of surgical training of candidates for the Final Fellowship examination should take effect as from Jan. 1, 1949.

It was resolved not to hold the Buckston Browne Dinner in 1947 on account of the food crisis.

A Diploma of Fellowship was granted to F. J. A. H. Blackwood (St. Thomas's Hospital).

A Diploma of Membership was granted to J. B. Binks (Birmingham).

A Diploma in Public Health was granted, jointly with the Royal College of Physicians of London, to A. McFarlane (Glasgow).

Diplomas in Tropical Medicine and Hygiene, in Ophthalmic Medicine and Surgery, and in Physical Medicine were granted,

jointly with the Royal College of Physicians of London, to the following successful candidates:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—G. T. Allen, J. H. C. Clarke, P.-L. Lim, H. J. A. Richards, W. P. Stamm, and to the candidates whose names were printed in the *Journal* of Aug. 23 (p. 313).

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.—S. Adler, L. P. Agarwal, R. M. Archer, N. K. Barber, J. Bienkowski, M. W. Bird, W. G. Bridges, K. B. Brown, R. A. Burn, Helena B. A. Casey, D. Christison, C. A. G. Cook, E. H. L. Cook, B. C. Curwood, L. W. Davies, E. A. Donegan, G. F. Ensor, K. B. Forsyth, D. P. Greaves, T. S. S. Gregory, F. B. Halliday, H. J. Hamelberg, J. M. Heller, C. R. S. Jackson, N. S. Jain, Sarah J. Jenkins, T. S.-B. Kelly, P. J. M. Kent, D. A. Langley, Marion McArthur, P. H. N. Matthews, W. S. Milne, D. G. Mody, E. S. Perkins, J. S. Phillpotts, F. C. Rodger, Maevae Rusk, M. H. M. Ryan, Q. R. Schindler, D. T. Shortridge, F. N. Shuttleworth, D. G. Simpson, C. S. Smalley, J. L. S. Smith, C. H. B. Sparrow, G. Sutherland, W. M. Walker, Nina S. S. S. Warwick, S. E. White, Eunice M. Wilson.

DIPLOMA IN PHYSICAL MEDICINE.—A. C. Boyle, M. C. Woodhouse, A. Zinovieff.

## The Services

Surgeon Lieutenant-Commander R. E. C. Copithorne, R.N.V.R., has been awarded the R.N.V.R. Officers' Decoration.

Captain W. F. Smith, R.A.M.C., has been awarded the Long Service and Good Conduct Medal, without gratuity.

Major J. P. Parkinson and Captain (Honorary Major) W. A. Bellamy, R.A.M.C., have been awarded the Efficiency Medal (Territorial).

The following appointments and mentions in dispatches have been announced in recognition of gallant and distinguished services while prisoners of war in the Far East:

M.B.E. (Military Division).—Major G. A. Graham, Major (temporary) B. M. Wheeler, Captains J. J. Woodward and J. P. Zachariah, and Lieutenants R. K. Saksena and T. A. J. Wickham, I.M.S.

Mentioned in Dispatches.—Major T. F. O'Donnel, Captains B. B. Choksi, R. S. Gupta, and P. M. Kirkwood, Jemadars I. S. Bedi and R. Ullah, I.A.M.C.

### DEATHS IN THE SERVICES

Flying-Officer CHARLES JOHNSON was killed in a flying accident on Sept. 17. A student of Durham University he graduated M.B., B.S. in December, 1945, at the age of 22. After a period as junior resident at the Royal Infirmary, Sunderland, he was granted a commission in the Medical Branch of the R.A.F. almost exactly a year ago. At the time of his death he was serving as medical officer at a Royal Air Force station in England.

Col. GEORGE KEITH FULTON, C.B.E., graduated M.B., Ch.B. at Glasgow in 1917 and before joining the R.A.M.C. was a house-surgeon at the Glasgow Royal Maternity and Women's Hospital.

Lieut.-Gen. Treffry O. Thompson writes: The sudden death of Col. George Fulton was a great shock and loss to those who had worked with him or known him well and a great loss to the Corps to which his life's work had been given. He had proved himself to be a great hygienist, both in peace and war. His knowledge of hygiene and preventive medicine was profound and wide, more particularly of course in its application to the armed Forces of the Crown and of India. But apart from mere knowledge he had that inestimable gift of common sense in the application which led to success in his contacts with every type of man and woman, and in his achievement of raising the hygiene of the Forces to a level second to none. Before his death he had the satisfaction of completing, among many other activities, two works typical of his determined energy and enthusiasm: the co-ordination of the multiple complicated documents which afflicted the medical services of the three armed Forces in India, and the 1946 Annual Hygiene Report, the last of the reports for the Army in India. The latter places on record the work of the hygiene branch and the preventive medicine of the medical services of India which, as deputy director of hygiene and pathology at General Headquarters, India, he so ably led to the end, and, in fact, shows that "records" in preventive medicine have been achieved. The sick rates and particularly the malarial rates for the Army in India constitute low records which have never before been achieved. George Fulton had the satisfaction of knowing that he himself had been very largely instrumental in producing those records and that excellent standard of health. He did a grand job and died peacefully in full harness.

The Minister of Health recently met at his personal invitation the members of the Regional Hospital Boards and discussed with them some of the problems that may occur. Mr. Bevan said that it was best to bring the members together at the start so that they might see themselves as part of a great health service—an integrated service in which they would not live in separate compartments.

No. 38

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 20.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis

The number of notifications of poliomyelitis in England and Wales in the week ended Sept. 27 was 441 (571) and of polio-encephalitis 32 (23). The figures for the week ended Sept. 22 are given in parentheses. Thus there was a fall of 130 in the notifications of poliomyelitis and a rise of 9 in those of polio-encephalitis. This is the largest fall in notifications since the epidemic began. Both in 1938 and in 1926, when there was a high prevalence, falls in incidence occurred in September but were followed by increases in early October. It is therefore too early to assume that the incidence will continue to fall, though the fact that the high incidence started early may be some justification for hoping that the decline may come early also.

The decline in London continued 30 (53), but figures for admissions to London hospitals since Sept. 27 suggest that the fall may not be so marked when the next weekly figures become available. Most of the counties showed decreases, the principal exceptions being Bedford 6 (3), Cheshire 15 (11), Lines (Lindsey) 16 (8), and Carmarthen 6 (2). The general picture is one of some decline, which is perhaps a little more noticeable in the South than in the North.

## Poliomyelitis in Germany

In July of this year a small outbreak of poliomyelitis was reported in the Friedrichshain district of Berlin. A score or more cases were limited to a block or two in this district. The incidence increased steadily and fresh notifications began to come in from all districts, although the majority still came from Friedrichshain and Lichtenberg in the eastern part of Berlin. By Aug. 17 the notifications had reached a total of just over 300; within a period of ten days this figure was more than doubled, and in one day there were as many as 69 notifications. The average daily number of notifications is now 18.

The clinical features of the present epidemic are unfamiliar to Berlin physicians. There are not so many cases of spinal paralysis as in former epidemics, and bulbar or meningeal signs are more frequent and tend to be associated with paresis of the third, sixth, and seventh cranial nerves. The age-incidence is as follows:

Age		Age	
0-3 years ...	7.5%	10-16 years ...	17.3%
3-6 " ...	26.9%	16-20 " ...	7.3%
6-10 " ...	24.5%	Over 20 " ...	17.2%

The highest proportion of fatalities is in the over 20 age group and largely in the better fed. In the ten weeks ending Sept. 29 there were 1,347 cases notified, with 118 deaths. Over this same period the incidence rate per 10,000 population was 19.0. Figures for former outbreaks in Berlin are given as: 1926-121 cases; 1933-213; 1937-460; 1939-359; 1941-472; 1942-274; 1943-149; and in each of the last three years there have been fewer than 100 cases.

In the present epidemic in Berlin, with a population of 3,300,000, the distribution of cases is as follows:

	Cases	Deaths
Russian Sector ...	782	75
U.S. Sector ...	314	25
British Sector ...	147	11
French Sector ...	104	7
Total ...	1,347	118

Patients with poliomyelitis are being treated in special hospitals by teams of physicians, orthopaedic specialists, and physiotherapists. Penicillin has been made available for cases complicated by pneumonia. A poliomyelitis commission has been flown over from America, and these experts have given advice and material aid to the German hospitals. Iron lungs have also been flown in from the U.S.A. The German officials could easily have had "iron lungs" made up from cast material, but they are slow in showing initiative of this sort. Some German physicians have been experimenting with insulin in certain cases; the rationale of this treatment is not known at present. Swimming-baths have been closed and the German authorities have been instructed to examine sewage farms and the like in regard to the possible spread of the virus.

So far no British personnel have been affected. One American sergeant who took part in a horse show in the British Sector on Sunday, Sept. 21, died of poliomyelitis on the following Tuesday.

In the British Zone of Germany up to Sept. 6 there had been 51 cases of poliomyelitis and 76 deaths, distributed as shown in the table among a population of 22,324,600.

	Cases	Deaths
Schleswig-Holstein ... ..	132	23
Niedersachsen ... ..	263	30
"Northrhine" Westphalia ... ..	159	16
Hamburg ... ..	97	7
Total ... ..	651	76

In the U.S. Zone and the U.S. Sector of Berlin from July 12 to Aug. 30 there were a total of 222 cases and 22 deaths, the highest figures being those for the week ending Aug. 30, when there were 71 cases and 11 deaths.

### Births and Deaths in Germany

We print below, from the August Monthly Report of the control Commission for Germany, two graphs showing the fluctuations in live births, deaths, and infant mortality in the British Zone of Germany, excluding the British Sector of Berlin, from June, 1946, to June, 1947.

Birth and death rates per 1,000 population per year.

Infant mortality per 1,000 live births.

### Discussion of Table

In England and Wales infectious diseases were more prevalent than in the preceding week. Rises in incidence were recorded for scarlet fever 131, acute pneumonia 49, dysentery 31, measles 8, diphtheria 27, cerebrospinal fever 10, and paratyphoid fever 10. Only whooping-cough 141 showed a decreased incidence.

The incidence of scarlet fever has been increasing steadily during the past four weeks; an increase of 85% in the number of notifications occurred during the month. During the week under review the rate of increase was fairly uniform in the various regions of the country.

The only large variation in the local trends of diphtheria was an increase of 15 in Lancashire due to the experience of the county boroughs. Notifications of whooping-cough declined in most areas; the largest fall was 61 in Essex. Little change occurred in the local trends of measles, apart from a rise of 42 in Somersetshire.

New outbreaks of dysentery were reported from Devonshire, t. Thomas R.D. 11, and Cornwall, Bodmin M.B. 8. The other large centres of dysentery were London 18 and Lancashire 12.

In Scotland only small changes were recorded in the incidence of infectious diseases. Decreases were reported for whooping-cough 29, scarlet fever 15, cerebrospinal fever 9, and acute poliomyelitis 7, while an increase of 8 was recorded in the notifications of dysentery—due to an outbreak affecting 10 persons in the city of Dundee. An increase in the notifications of poliomyelitis occurred in the eastern area, where the cases rose from 18 to 31.

In Eire infectious diseases were less prevalent and falls were recorded for whooping-cough 27, diarrhoea and enteritis 28, and measles 29.

In Northern Ireland the only change of note in the trends of infectious diseases was an increase of 16 in the notifications of scarlet fever due to a small general rise.

### Health of Scotland

The Department of Health for Scotland in its first full report since before the war has reviewed the period from July, 1945, to December, 1946. In 1946 the birth rate was 20.3 per 1,000, the highest rate since 1926. The infant mortality rate was 53.8 per 1,000 live births, the lowest on record, while the maternal mortality, 2.2 per 1,000 total births, was also the lowest rate ever recorded. Notifications of diphtheria declined from 12,391 in 1941 to 4,988 in 1946. Deaths from pulmonary tuberculosis numbered 2,932 in 1945 and 3,226 in 1946. Deaths from non-pulmonary tuberculosis totalled 871 in 1945 and 757 in 1946. The number of new cases of venereal disease in 1945 was 10,051, compared with 13,651 and 10,651 in 1943 and 1944; the figures for 1946 show a substantial rise.

### Quarterly Returns for England and Wales

The birth rate during the June quarter was 22.0 per 1,000, compared with 22.8 for the preceding quarter and 16.6 for the average of the second quarters for the five years 1941-5. The infant mortality rate was 40 per 1,000 live births and was 9 below the average rate for the June quarters of the preceding ten years. The general death rate was 11.1, compared with 10.7 for the preceding second quarter and 11.3 for the average of 1941-5. During the quarter 60 cases of smallpox were notified, and 8 deaths were attributed to this cause.

### Week Ending September 27

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 880, whooping-cough 1,105, diphtheria 184, measles 1,139, acute pneumonia 257, cerebrospinal fever 30, acute poliomyelitis 441, acute poliomyelitis 32, dysentery 87, paratyphoid 10, and typhoid 22.

## Medical News

### Register of Chiropodists

A new *Register of Chiropodists* has been published by the Board of Registration of Medical Auxiliaries, and medical practitioners can obtain copies free on application to the Registrar of the Board at Tavistock House (North), Tavistock Square, London, W.C.1.

### Van Meter Prize

The American Association for the Study of Goiter again offers the Van Meter Prize Award of three hundred dollars and two honourable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The Award will be made at the annual meeting of the Association, which will be held at King Edward Hotel, Toronto, Canada, May 6-8, 1948, providing essays of sufficient merit are presented in competition. The competing essays may cover either clinical or research investigations; should not exceed 3,000 words in length; must be presented in English; and a typewritten double-spaced copy be sent to the corresponding secretary, Dr. T. C. Davison, 207, Doctors' Building, Atlanta, 3, Georgia, not later than Feb. 1, 1948.

### March of Doctors

"Your Doctors To-day," the new March of Time film which began its West End run at a Leicester Square cinema last week, is a survey of recent discoveries in the field of medicine and surgery. The camera moved briskly from Prof. Henry C. Sherman carrying on nutritional experiments at Columbia University to Dr. V. G. Korenchevsky at Oxford. The use of the artificial kidney is shown and so is the application of radio-iodine in the treatment of cancer of the thyroid. Lord Horder appears in an introductory shot which leads on to some of the rehabilitation work being done at Roffey Park. Some features of modern psycho-analysis are dramatically depicted, and there are many other points in this film which will interest most doctors. They may become a little wistful, however, on seeing great quantities of streptomycin displayed in an American chemist's shop. The commentary is spoken in English by Alistair Cooke.

### Neurology Research Grant

The Burden Neurological Institute at Bristol has been granted £12,500 by the Rockefeller Foundation for the purpose of research in neurophysiology and neurosurgery.

**Eire Medical Grants Doubled**

The existing Eire Government grant of £5,000 a year to the Medical Research Council of Ireland has now been doubled, as has the usual £3,000 annual grant for research into the treatment of tuberculosis. These grants are guaranteed for five years and are likely to be renewed afterwards. The sums will enable research workers to be adequately remunerated, essential apparatus to be procured, and accommodation at medical schools, hospitals, and universities to be improved.

**Private Secretary to Minister of Health**

The Minister of Health, the Rt. Hon. Aneurin Bevan, M.P., has appointed Mr. E. J. S. Clarke to be his private secretary.

**Christmas Cards**

The Grenfell Association of Great Britain and Ireland, which carries out medical work among settlers in Labrador and Northern Newfoundland, has produced a delightful range of Christmas cards at a reasonable price. They are obtainable at prices ranging from 5d. in black and white to 1s. in colour, envelopes included, post-cards in black and white at 2d. each, and six reproductions of seascapes at 2s. a packet. An illustrated leaflet can be supplied for 1d. They may be obtained from the Secretary, The Grenfell Association, 66, Victoria Street, London, S.W. For the philatelist packets of stamps (no duplicates) are available containing 18 British Commonwealth for 1s. 6d. or 7 mint U.S.A. for 1s. Orders should be sent to Mrs. D. W. Mackay, 88, Exeter House, Putney Heath, S.W.15. The Grenfell Mission is still in desperate need of funds if it is to continue the only medical and social service that exists in these snowy outposts, and we take this opportunity of drawing the attention of our readers to these cards.

**Summer Schools in Health Education**

Two Summer Schools in Health Education were held this year by the Central Council for Health Education under the direction of Dr. Robert Sutherland, assisted by Dr. N. Parfit, Miss P. M. Taylor, and Mrs. K. M. Catlin. Of every seven students attending the schools one was a medical practitioner or medical student, two were nurses, two were teachers, and two were social or health education workers. The students came from Great Britain, Eire, India, Belgium, Czechoslovakia, Denmark, Portugal, and Sweden. The school at Keble College, Oxford, was held from July 25 to Aug. 8, and that at Bede College, Durham, from Aug. 20 to Sept. 3. Lectures on general background studies were given in the mornings at each school by four lecturers working as a team. At Oxford Prof. H. P. Gilding spoke on "The Physiology of Growth," Prof. C. W. Valentine on "Psychology," Dr. Maurice Mitman on "The Biology of Infection," and Dr. Robert Sutherland on "Social Factors Affecting Health." At Durham these lectures were given by Dr. T. E. Barlow, Miss Anna Freud, Dr. Robert Cruickshank, and Mr. Leonard England respectively. Evening lectures, given by speakers prominent in the fields of medicine, education, or industry, covered the wider aspects of health education in the field. Discussion groups were led by the students, speaking in the first week to small groups representing a cross-section of the school and later to their own professional groups. Tuition in physical recreation and ball-room dancing, under expert leadership, was much appreciated, as were opportunities for taking part in local expeditions, tennis, swimming, and other sports. Civic welcomes were much appreciated and enjoyed. At both Oxford and Durham the Mayor and Mayoress entertained the students.

**Wills**

Dr. John Brook Henderson Holroyd, of Sheffield, who died on Feb. 8, left £2,839. Dr. John Dewar Robson, of Dumfries, who died on April 26 last, left £3,773. Dr. Kenneth Robert Hay, O.B.E., of London, W.14, who died on March 12, left £48,221, and he bequeathed £300 to St. Bartholomew's and £250 to the Royal Medical Benevolent Fund.

**COMING EVENTS****National Institute for the Deaf**

The annual general meeting of the National Institute for the Deaf will be held at the Connaught Rooms, Great Queen Street, Kingsway, London, W.C., to-day (Friday, Oct. 10), at 2.30 p.m., when the Duke of Montrose will preside.

**Zoological Society**

The next meeting of the Zoological Society of London for scientific business will be held on Tuesday, Oct. 14, at 5 p.m.

**Edinburgh Clinical Club**

The first meeting of the 1947-8 session of the Edinburgh Clinical Club will be held at B.M.A. House, 7, Drumsheugh Gardens, Edinburgh, on Thursday, Oct. 16, at 8 p.m., when Dr. J. D. S. Cameron will open a discussion on "Modern Drugs in General Practice."

**Institute of Public Administration**

Mr. L. John Edwards, M.P., Parliamentary Secretary to the Ministry of Health, will deliver the first of a series of lectures arranged by the Institute of Public Administration (18, Ashley Place, Victoria Street, London, S.W.1) at King's College, Strand, London, W.C., on Tuesday, Oct. 14, at 6 p.m. His subject is "Building Health Service." Full particulars of the other lectures, which will be delivered on Nov. 4 and Dec. 2, 1947, and Jan. 13, Feb. March 2, April 6, and May 4, 1948, can be obtained from the director of the institute. The fees for admission to the lectures are: Members, 5s., and non-members, 12s. 6d., for the whole series; individual lectures, 2s. 6d.

**Royal Medical Society of Edinburgh**

The Royal Medical Society of Edinburgh, which was founded in 1737, opens its 1947-8 session with an address by the Marquis of Linlithgow, Chancellor of the University of Edinburgh, on "Medical Rehabilitation" on Friday, Oct. 17, at 8 p.m. at the Society's Hall, 7, Melbourne Place, Edinburgh. Other meetings will be announced in the diary column of the *Journal* for appropriate weeks.

**Irish Tuberculosis Society**

The annual general meeting of the Irish Tuberculosis Society will be held at Crookslings Sanatorium, Co. Durham, on Friday, Oct. 1 at 4.15 p.m., and will be followed by a clinical meeting at 5 p.m. when Dr. Arthur Walsh will speak on "Trends in Treatment Pulmonary Tuberculosis in Scandinavia." At 5.30 p.m. Dr. P. Dunleavy will discuss "Dispensary Organization in Tuberculosis in Scandinavia," and at 6.30 p.m. Dr. Peter W. Edwards will present "Some Essential Requirements in Tuberculosis Schemes." Membership of the Society is open to all registered medical practitioners on an annual subscription of 10s. 6d. The address of the honorary secretary is the Hospital, Newcastle, Co. Wicklow, Eire.

**Prevention of Blindness**

The National Society for the Prevention of Blindness announces that a three-day conference will be held at Hotel Radisson, Minneapolis, Minn., U.S.A., on April 5, 6, and 7, 1948. The conference will be of interest to persons who are directly or indirectly concerned with eye health and safety. Details concerning the programme may be obtained from the society at 1790, Broadway, New York 19, N.Y., U.S.A.

**SOCIETIES AND LECTURES**

**ROYAL COLLEGE OF PHYSICIANS OF LONDON**, Pall Mall East, S.W. Saturday, Oct. 18, 3 p.m. Harveian Oration by Dr. C. E. Lask. Our Founders and Benefactors.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND**, Lincoln's Inn Fields, W.C.—Thursday, Oct. 16, 3.45 p.m., Surgery Lecture by Prof. John H. Garlock, Surgical Treatment of Carcinoma of the Oesophagus and Upper Stomach; Friday, Oct. 17, 5 p.m., Hunterian Lecture by Prof. Murray A. Falconer, A Study of Principles and Results of Lumbar Intervertebral Disk Surgery.

**ROYAL SOCIETY OF MEDICINE**

**Section of Psychiatry**.—Tuesday, Oct. 14, 5 p.m. Presidential Address by Sir David Henderson: Psychiatric Hypothesis as Practice.

**Section of Comparative Medicine**.—Wednesday, Oct. 15, 5 p.m. Presidential Address by Mr. R. E. Glover: The Influence of the Small Animal Breeder on Biological Research.

**Section of Dermatology**.—Thursday, Oct. 16, 5 p.m. (Cases 4 p.m.)

**Section of Obstetrics**.—Friday, Oct. 17, 8 p.m. Discussion: Post-operative Thrombosis. Openers: Drs. Helen P. Wright and Magnus Haines, and Messrs. A. Dickson Wright and Leslie Williams.

**Section of Radiology**.—Friday, Oct. 17, 8 p.m. Paper: Dr. R. G. Reid: Inter-atrial Septal Defect—A Radiological Study of Recent Cases.

**BRITISH INSTITUTE OF PHILOSOPHY**.—At University Hall, 14, Gower Square, London, W.C., Friday, Oct. 17, 5.15 p.m. Mr. H. Lewis: Religion and Morality.

**LONDON: UNIVERSITY COLLEGE**, Gower Street, W.C.—Thursday, Oct. 14, 5.15 p.m. Prof. J. Z. Young, F.R.S.: Structure, Peripheral Nerve and of Nerve Endings. Wednesday, Oct. 15 p.m. Dr. M. H. Pirenne: Physiological Mechanisms of Vision.

**MEDICAL SOCIETY OF LONDON**, 11, Chandos Street, W.—Monday, Oct. 13, 8 p.m., General Meeting; 8.30 p.m., Pathological Meeting.

**ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE**, 28, Portico Place, W.—Wednesday, Oct. 15, 3.30 p.m. Prof. J. L. Sedgwick: Infantile Paralysis (Illustrated).

**ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE**.—At 26 Portland Place, W., Thursday, Oct. 16, 7.30 p.m., Presidential Address by Sir Philip Manson-Bahr: The Practice of Tropical Medicine in London.

## POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At West Medical Lecture Theatre, Edinburgh Royal Infirmary, Tuesday, Oct. 14, 5 p.m. Dr. R. McWhirter: Living Crystals.

EDINBURGH ROYAL INFIRMARY.—Thursday, Oct. 16, 4.30 p.m. Honyman Gillespie Lecture by Dr. A. S. Paterson: Electro-shock and Electroanesthesia in the Treatment of Mental Disorders.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—Wednesday, Oct. 15, 8 p.m. Prof. A. J. Ballantyne: Some Problems in Ophthalmoscopic Diagnosis.

LONDON CHEST HOSPITAL, Victoria Park, E.—Friday, Oct. 17, 5 p.m. Mr. T. Holmes Sellers: Surgery of the Heart and Pericardium.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tuesday, Oct. 14, 5 p.m. Dr. I. Muende, Pathological Demonstrations.

The Edinburgh Postgraduate Board for Medicine has arranged, in connexion with the postgraduate courses in medicine and surgery, a series of open lectures on subjects of wide biological interest to be given in the West Medical Lecture Theatre of the Royal Infirmary on alternate Tuesdays from Oct. 14 to Dec. 9, at 5 p.m. All graduates and students are invited to attend the lectures, details of which will appear in the diary column of the *Journal* for the appropriate weeks.

The Fellowship of Medicine announces the following courses: (1) Obstetrics and gynaecology, at Nuffield Department of Obstetrics and Gynaecology, Radcliffe Infirmary, Oxford, all day from Oct. 21 to 31. (2) Week-end course in rheumatic diseases, at Rheumatic Unit, St. Stephen's Hospital, Fulham Road, S.W., all day Saturday and Sunday, Oct. 25 and 26. (3) Week-end course in general medicine and surgery, all day Saturday and Sunday, Oct. 18 and 19. (4) Course in proctology, at St. Mark's Hospital, City Road, E.C., all day, Oct. 27 to Nov. 1. Full particulars can be obtained from the Fellowship of Medicine, 1, Wimpole Street, London, W.

An additional clinico-pathological meeting will be held on Monday, Oct. 20, at 5 p.m., in the Meyerstein Lecture Theatre, Westminster Hospital School of Medicine, Horseferry Road, S.W., when a sound film on the detection of unsuspected tuberculosis in hospital out-patients (running time 20 minutes) will be shown and generalized amyloidosis in pulmonary tuberculosis discussed.

A concentrated week-end course on the chronic rheumatic diseases for general practitioners and demobilized officers will be inaugurated by Lord Moran, P.R.C.P., at the L.C.C. Rheumatism Unit, St. Stephen's Hospital, Fulham Road, S.W., on Saturday, Oct. 25. Full details of the course can be obtained on application to the Fellowship of Postgraduate Medicine, 1, Wimpole Street, London, W.1.

## APPOINTMENTS

Kenneth Cowan, M.D., D.P.H., has been appointed Senior Administrative Medical Officer to the South-West Metropolitan Regional Hospital Board.

Dr. Cowan has been medical officer of health and school medical officer for Gloucestershire for the past ten years and was formerly deputy medical officer of health for Leicestershire.

KENT AND SUSSEX HOSPITAL.—Honorary Assistant Physician: P. T. Cooper, M.B.E., M.D., M.R.C.P. Honorary Anaesthetist: G. P. Goodwin, M.R.C.S., L.R.C.P., D.A.

MACPHERSON, IAN, M.D., M.R.C.P., Honorary Physician, Leeds Public Dispensary and Hospital.

MILLER, C. M., M.D., M.R.C.P., Assistant Physician, Smithdown Road Hospital, Liverpool.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 wards or less. Extra wards 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

## BIRTHS

ADAM.—On Sept. 18, 1947, to Dr. and Mrs. R. H. Adam, 71, Busby Road, Clarkson, Renfrewshire, a daughter.

CHADWICK.—On Aug. 31, 1947, at Manchester, to Sybil (née Kinsey Williams), wife of Lieut. D. A. Chadwick, R.A.M.C., a daughter—Jacqueline Anne.

FERREIRA.—On Oct. 3, 1947, at the Wimbledon Nursing Home, to Joan (née Hilditch), wife of Dr. Harold Ferreira of 22A, Arterberry Road, Wintledon, a son.

HEAP.—On Oct. 1, 1947, at Scarborough, to Betty (née Heather), wife of Dr. K. I. Heap, "One Oak," Pickering, Yorks., a daughter.

NEAL SMITH.—On Oct. 1, 1947, at Queen Charlotte's Hospital, to Joan, wife of D. J. Neal Smith, M.D., M.R.C.O.G., a daughter—Susan.

SUMNER.—On Sept. 22, 1947, at Newcastle General Hospital, to Audrey (née Hutchison), wife of Dr. John Sumner, M.C., M.D., a son—Jeremy Hutchison.

WOODS.—On Sept. 19, 1947, in Dublin, to Valerie, wife of Dr. F. B. B. Woods, a son.

## MARRIAGE

HARVEY—WOODWARD.—On Sept. 27, 1947, at St. Peter's, Littleover, Norman William Allan Harvey, M.B., B.S., to Betty Woodward.

## DEATHS

DICKSON.—On Sept. 17, 1947, at 95, Rose Hill, Oxford, Francis Henry Dickson, M.B., Ch.B. (Edin.), aged 67.

STROVER.—On Sept. 27, 1947, at 90, Redland Road, Bristol, Henry William Martyn, O.B.E., M.B., Ch.B., aged 71.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

## Abdominal Actinomycosis

**Q.**—A patient with caecal and hepatic actinomycosis has had intensive treatment with penicillin, sulphonamides, and iodides for three months; her sinuses have now healed and she is afebrile, but there is still induration in the right loin. How long should treatment be continued? What is the probability of relapse? Is the condition still considered invariably fatal when the above remedies are used?

**A.**—The advent of penicillin has entirely altered the outlook and prognosis in abdominal actinomycosis: the condition is now much more amenable to treatment and cure. It is, however, necessary to give large doses of penicillin for long periods without intermission—half a million units daily until all evidence of the disease has disappeared. The induration in the loin should serve as a warning that recurrence will take place unless the penicillin treatment is continued. The drug need not be given in frequent small doses; one daily dose of half a million units will serve. It can be given in small bulk, and will not cause discomfort if a few drops of local anaesthetic are added to it. In this case skiagrams of the hepatic region should be taken to see if there is any enlargement of the liver upwards: rupture of a hepatic abscess into the lung sometimes occurs, and this would modify the prognosis.

## Syphilitic Aortitis

**Q.**—Is it correct that in syphilitic aortitis good results have been obtained with penicillin preceded by a course of bismuth? If so, would you give me details of dosage, duration, etc. I believe there is a danger of a Herxheimer reaction in these cases. What precautions should be taken to prevent this, and, should it occur, what would be the immediate treatment?

**A.**—Yes, bismuth and penicillin are indicated, but too much must not be expected in the way of results. First a course of intramuscular injections of an insoluble bismuth preparation should be given, starting with 0.05 g. of bismuth metal and increasing gradually to 0.2 g.; injections should be given every five to seven days; at the same time large doses of potassium iodide should be prescribed up to the limit of tolerance. At the end of three months penicillin may be employed, in small doses at first; for example, 5,000 units three-hourly, increasing gradually to 20,000 units; the total dosage should be 4 mega units if no untoward reactions occur. A severe Herxheimer reaction might be very dangerous; it can be prevented by using mild therapeutic measures at first. Should such a reaction occur symptomatic treatment is indicated.

## Correction of Presbyopia

**Q.**—In the treatment of presbyopia where it may be necessary to incorporate prisms in the lenses to relieve the internal recti—as in instances where the near point has to be brought closer than is ordinarily desirable—it is said that the prisms should be of a strength to bring the near point of convergence to that of accommodation, and that the strength of the prisms normally corresponds to that of the sphere required. By "sphere required" I presume is meant the presbyopic correction. Is this so? Also, should the strength of the prism before each eye be that of the sphere, or should a prism the strength of the sphere be divided between the two eyes?

**A.**—In tasks performed closer to the eyes than that of reading, the use of prisms together with spheres stronger than those required for reading is of definite advantage. In such cases the prism should be equally divided between the two eyes. Tables have been compiled and were printed before the war showing the sphere and prism to be added to the distance correction for varying distances at the ages of 40, 45, 55, and 65

and taking into consideration the interpupillary measurement. Such tables form a useful basis for prescribing, but in every case the problem must be considered on its own merits and no hard-and-fast rule connecting sphere and prism should be slavishly followed.

### Food Allergy

**Q.**—An infant of 13 months who had a very severe attack of gastro-enteritis just after birth suffers from extreme collapse followed by vomiting and diarrhoea almost immediately after being given egg, even in minute amounts; the attack lasts about eighteen hours. On several occasions, unrelated to any specific food, he has had a cutaneous eruption similar to lichen urticatus; otherwise he is perfectly healthy. How should he be treated? Is there any danger in immunizing against diphtheria and/or pertussis, and what preparation should be used?

**A.**—Symptomatically, elixir "benadryl," 0.5 to 2 mg. per lb. body weight daily, divided into four doses, is likely to help the irritation. Thermal factors, environmental factors, and food allergy all play a part in this disorder. Investigation is by trial dieting, eliminating and later reintroducing suspected foods, as skin tests in this condition are not reliable. Treatment consists in elimination of any proved food allergen. Immunization of an allergic child with diphtheria toxoid and pertussis vaccine is without risk.

### Small Stature

**Q.**—Can anything be done about a girl aged 17, just over 5 feet (152 cm.) in height, who appears to have stopped growing? She is at school and her general health is good. Both sides of the family are above average height.

**A.**—In most girls the epiphyses are united at the age of 17, and in many at the age of 15. Growth is therefore unlikely in this case under any treatment. The usual treatment when the epiphyses are ununited—as can, of course, be seen by x rays—is by thyroid extract and injections of anterior pituitary growth hormone. On the whole the latter is clinically disappointing and does not fulfil the high expectations of animal experiments.

### Diaphragm Pessary

**Q.**—When fitting a diaphragm pessary how is the size required by a particular patient decided? How often is it advisable to check the fitting—with special reference to a patient who has had a child (by normal delivery) two months ago?

**A.**—It is customary to choose the largest diaphragm pessary which will reach from the posterior fornix into the small sulcus behind the pubic bone. It should fit tightly but stay up when the patient bears down. By no means all women can wear this type, and a sloping anterior vaginal wall is a frequent contraindication. A "Dumas" type of pessary is then required. Relevant information will be found in the article on contraception in Butterworth's *Encyclopaedia of General Medicine*. The woman could be fitted in the puerperium, but it is often advisable to refit after three or four months, or when the baby is weaned.

### Enteritis and Steatorrhoea

**Q.**—For some years a patient has had alternating attacks of diarrhoea and constipation, diagnosed as intestinal carbohydrate maldigestion. Two months ago there was an attack of acute enteritis with pale, fatty, liquid stools. Improvement has taken place on a fat-free diet, but the stools remain pale and he has lost weight. He has previously been treated with arsenic for the control of a long-standing dermatitis herpetiformis. Has this any bearing on the present condition? What treatment should be prescribed?

**A.**—It is not rare for an attack of acute enteritis to be followed by a period of steatorrhoea. This seldom lasts more than a few weeks, and in most instances the bowel habit and the character of the stools rapidly return to normal. The cause of this transient defect in fat absorption is unknown, but it is noteworthy that tropical sprue may be a sequel of the acute enteritis known as hill diarrhoea. It has been suggested that changes in the flora of the bowel may be responsible for these attacks.

While steatorrhoea continues, it is wise to restrict fat. Symptomatic improvement has followed nicotinic acid (50 mg. four

times daily), and folic acid (20 mg. daily) is worth a trial. Neither of these substances causes a significant increase in the absorption of fat, but this has been noted after full doses of yeast extract. It is improbable that arsenic plays any part in the causation of the symptoms. These therapeutic suggestions are made on the assumption that organic disease of the bowel has been excluded.

### Treatment of Obesity

**Q.**—Do you consider ammonium chloride a better treatment for obesity than thyroid?

**A.**—These substances act quite differently. Ammonium chloride is a diuretic and is given because adiposity is often associated with some element of water retention; and also because low-calorie diets are effective up to a certain point, when weight becomes stationary and no further progress is made. Diuretics are given to remove an accumulated retention of fluid. Thyroid acts by increasing the metabolic rate, but as its effect is on protein its use is not logical in the absence of evidence of associated thyroid deficiency. It is dangerous in larger doses where fatty infiltration of the heart is suspected. In moderate doses it is used as an adjunct to therapy even in the absence of a lowered basal metabolism, and it may be of some help as an auxiliary method of treatment.

### Tobacco and Poliomyelitis

**Q.**—Is there any evidence that non-smokers are more susceptible to poliomyelitis than smokers? Children are non-smokers and are very susceptible.

**A.**—A very large number of possible factors influencing susceptibility to the virus of poliomyelitis have been studied in U.S.A. and other countries where the disease is endemic; there have been many epidemics. It is unlikely that if tobacco smokers were less susceptible to poliomyelitis virus than non-smokers (other than children) it would have gone unnoticed.

## NOTES AND COMMENTS

**Angina Pectoris.**—Dr. C. W. F. McKean (London, W.1) writes: Your questioner (Sept. 13, p. 439) should be reminded to do a W on his patient, as the atypical angina pectoris he describes—sternal pain radiating to the arm, but less severe and of longer duration than true angina of effort—in the absence of hypertensive arteriosclerosis, or valvular disease, is one of the ways in which specific aortitis may present itself.

**Funds for X-ray Plant.**—As a result of an appeal for funds (Sept. 20, p. 476) to provide an x-ray plant for the London Missionary Society £54 15s. has been subscribed. The Victoria Hospital, Kingston-on-Thames, kindly provided an x-ray diagnostic unit, and another £250 is still required to meet the cost of transporting the unit and its transport to India. Contributions would be gratefully received by Dr. Cecil Cutting, London Missionary Society, 42, Broadway, London, S.W.1.

### Corrections

It was Prof. Lambert Rogers who introduced Dr. Albin Blalock, professor of surgery at Johns Hopkins University, Baltimore, for admission to the Honorary Fellowship of the Royal College of Surgeons of England, and not Prof. H. W. Rodgers reported in the *Journal* of Sept. 27 (p. 505).

A small, but vital, printer's error crept into the summary of Dr. McWhirter's paper on carcinoma of the breast (*Journal*, Oct. 4, p. 542, column 2, line 18, "the first-year" should read "the 5-year survival rate was 50.1%."

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 11 1947

## INSURANCE ACTS COMMITTEE

### The Information on Certificates

One of the longest meetings of the Insurance Acts Committee of recent years—lasting four and a half hours—was held, under the chairmanship of Dr. E. A. Gregg, on Sept. 25. The deaths of two members of the committee, Dr. S. E. A. Acheson, a representative of Northern Ireland, and Dr. J. W. Hunter, representative of the Society of Medical Officers of Health, were reported and tributes paid.

Dr. A. Massey, chief medical officer of the Ministry of National Insurance, attended to discuss with the committee a proposal to include in the wording of certificates to be used by general practitioners under the National Health Service Act a reference to the patient's employment. He said that his department, in considering the new National Insurance scheme, had felt that it would be advantageous to obtain from certificates information about morbidity, in which employment was an important factor, which would assist in prevention. The patient's own description of his employment was often too vague to be of much use, but the doctor, as a result of his talk with the patient, might be expected to give a description which would lend itself to better classification. Another point was that in the certificate handed to the patient it was sometimes undesirable to state the illness from which the patient was suffering, and a vague certificate was given. It was now suggested that there should be attached to the final certificate a slip on which the real nature of the illness might be stated and which might be torn off and sent to the Ministry.

It was pointed out in discussion that the useful information from the morbidity point of view was often not the patient's present occupation but his previous one, as for example the phthisical patient who had left coal-mining for gardening. It was also suggested that such a requirement might prove to be onerous in view of the many changes in occupation which a man might have, and the difficulty of some technical descriptions. One member of the committee, while fearing that there might be an enlargement of such duties thrust upon the practitioner, said that he had gathered that the information which the patient gave to his doctor about his occupation was almost invariably more accurate than that which he gave to the insurance agent.

If it could be proved that this information about occupation could be obtained in no other way there was much in the argument that doctors should accede to the request. On the other matter, the statement of the real nature of the illness on the slip to be sent to the Ministry, the question of confidence came in, and Dr. Massey agreed that it required some further thought.

It was mentioned that the Ministry had set up a small committee on the general question of certification, to which the Association would tender evidence.

Prof. G. S. Wilson attended to explain the scope and facilities of the new laboratory service. A report of his statement is given on p. 86.

### Reports to Practitioners

It was reported that the Ministry of Health still considered it not practicable, during the limited time remaining of the present insurance scheme, to adopt the committee's suggestion that the patient's own doctor should be given an opportunity

of arranging for an examination by a specialist in all cases where the regional medical officer considered that a second opinion was desirable. The Ministry was similarly unmoved by the request that the doctor should be allowed to issue a special intermediate certificate in connexion with pregnancy sickness benefit, without waiting for the qualifying period of 28 days to elapse, in cases where the doctor was satisfied that the patient would not be capable of work after her confinement.

Dr. Gregg said that both these questions would be kept on the list and brought forward on every occasion on which they went to the Ministry.

On the findings obtained in mass radiography the Minister was more amenable. He considered it desirable that even negative findings, that the chest condition was normal, should be notified to the patient's doctor. The feeling of the committee, however, was that it was not the best course, as the Ministry proposed, that such negative finding should be recorded on a card to be handed to the patient for the information of his doctor if he had occasion to go to him for advice or treatment, but that the notification should be sent to the doctor direct.

### Week-end Arrangements by Practitioners

The committee considered a scheme put forward by the Birmingham Insurance Committee for week-end rota arrangements by practitioners. It was agreed that the Editor be requested to publish the scheme in the *Journal*, but the committee withheld any comment. One member pointed out the difficulty in rural areas in making arrangements for transfer of telephone calls.

A request from the London Panel Committee for views on the advisability of endeavouring to secure an increase in the existing scale of fees for emergency treatment was considered. Dr. Gregg said that in London it was felt that these fees were too low, but any increase should be on a national basis. The opinion of the Insurance Acts Committee was that the fees should be increased to a figure which would not be an embarrassment in any negotiations, and that panel committees should be communicated with, attention being drawn to the position. Uniformity was felt to be very important.

It was agreed also to take up with the Ministry a request from the London and West Riding Panel Committees for the upward revision of the capitation fee for emergency drugs and appliances. It was pointed out that the drugs had become more expensive. The capitation fee at present varies from 1s. 3d. to 2s. 6d., the higher fee obtaining in areas where local conditions impose upon general practitioners abnormal liability for supply of dressings.

On a resolution from the Somerset Panel Committee requesting action for doctors' priority in the sale of new cars, it was stated that 10,000 doctors were waiting for cars, in which state of affairs, of course, priority ceased to have any effectiveness. It was pointed out that when the basic petrol ration came to an end a new supply of second-hand cars might become available for purchase.

The committee agreed to the principle of "one man, one vote" on national issues—in other words, if a practitioner was on the panel in two areas he should vote only in one. It was remitted to the office to prepare a detailed scheme.

A report on the National Insurance Defence Trust was given by Dr. Bone. Subscriptions during the previous five months had been three times what was received during the whole of last year. The fund was now approaching the half-million.

## PUBLIC HEALTH LABORATORY SERVICE

## FACILITIES FOR GENERAL PRACTITIONERS

Prof. G. S. Wilson, Director of the Public Health Laboratory Service, gave an address at a meeting of the Insurance Acts Committee on Sept. 25 on the scope and facilities which the new service affords to general practitioners. He reminded the committee of the decision, made when war seemed to be impending, to establish an Emergency Medical Service with which, wherever possible, pathological laboratory facilities were to be associated. The Medical Research Council was asked by the Committee of Imperial Defence to run the Emergency Public Health Laboratory Service on a national basis, and the Council thereupon made its preparations, establishing a number of laboratories in different parts of the country, and the service came into operation at the beginning of the war. At the end of the war it was considered inadvisable to discontinue a service which had proved extremely useful, and provision was made in the National Health Service Act for its continuance on a peacetime basis.<sup>1</sup>

The Public Health Laboratory Service, unlike other features of the Act, came into operation immediately, without waiting for any "appointed day." The Medical Research Council agreed to administer the service, at least for an initial period of five years. In taking this decision the Council was influenced by the big opportunities afforded for research not only in the laboratory but in the field. Under the Act there would be two administratively distinct pathological services, one related to hospitals and the other to public health in the field of bacteriology and epidemiology. While the hospital pathological service was concerned essentially with the treatment of the individual patient, the Public Health Laboratory Service concentrated, in conjunction with the medical officers of health, on the diagnosis, prevention, and control of infectious disease in the community as a whole. The hospital pathologist's work was therapeutic; the public health pathologist's work was preventive. The hospital pathology service would come under the Regional Hospital Board; the public health laboratory service would be on a national basis and would be run on behalf of the Ministry of Health. In the bacteriological diagnosis of infectious disease the two services would overlap to some extent, but precautions were being taken to avoid trouble from this cause. Presumably the hospital service would come into operation on July 5; the other service was now being developed. It would provide, so far as possible, free diagnostic facilities for dealing with infectious diseases, including all respiratory and intestinal and other forms of infection, but excluding venereal disease.

The headquarters of the service were in the office of the Medical Research Council, and the main Central Public Health Laboratory—really a congeries of laboratories—was at Colindale. Regional public health laboratories were established in some of the university towns—Oxford, Cambridge, Cardiff, Newcastle—and it was hoped to extend these later on. Meanwhile, other university laboratories were being associated with the service. Area laboratories, roughly equivalent to county laboratories, but not working within strict county limits, were so in existence, and arrangements were being made with hospital laboratories in smaller districts for the examination of public health laboratory specimens. In addition there were a series of reference laboratories, many of them centred at Colindale, for special diagnosis and identification work. For example, the central enteric reference laboratory was engaged in the Vi-phage typing of typhoid and paratyphoid strains and in keeping a record of enteric carriers throughout the country; the *Salmonella* reference laboratory was responsible for the serological identification of organisms of the food-poisoning group, which now numbered over 160; the streptococcal reference laboratory undertook the serological typing of haemolytic streptococci from scarlet fever, puerperal fever, and wound infections, as well as the phage typing of staphylococci, which was becoming of increasing importance in the investigation of

pemphigus and of food-poisoning outbreaks; the virus reference laboratory helped in the serological diagnosis of smallpox, and carried out investigations on influenza and poliomyelitis. There was also a standards laboratory, which supplied diagnostic reagents to laboratory workers, and provided the agents occasionally needed by the practitioner for the diagnosis of trichiniasis, hydatid disease, lymphogranuloma inguinale, and undulant fever.

## Consultative Service

So far as general practitioners were concerned, Prof. Wilson said that what was proposed to be provided was a consultative service. The service hoped to be in as close touch with general practitioners as possible and to help them in the diagnosis of all cases of infectious disease of any public health importance. It was responsible for the distribution of A.P.T. and T.A.F. for diphtheria prophylaxis; and it was supplying now to vaccination officers, and would supply direct to general practitioners as soon as the Act came into operation, vaccine lymph for vaccination against smallpox. Most of the other materials for vaccination against typhoid, cholera, and the like would be supplied probably through the ordinary commercial agencies, and general practitioners might have to make their own arrangements; this was still undecided. He added that a complete service covering the whole country could not be given at the present time, and it might be ten or twenty years before the country was covered adequately; but the service was gradually expanding, and it was hoped that practitioners in areas in which there were laboratories would not hesitate to make the utmost use of them.

In reply to a question on the relation of the new service to the public health service already in existence in large cities, Prof. Wilson said that what had been done with many of the pre-existing public health laboratories was, with the consent of the local authorities concerned, to take them over completely, relieving the local authorities of the responsibility for running them, and employing the staffs already there, supplementing them if necessary. If local authorities preferred to run their own laboratories, of course the new service would not intervene. Asked about the situation in the North of England, he said that there were laboratories at Wakefield for the West Riding and at Northallerton for the North Riding; there was an associated laboratory at Leeds; the Bradford laboratory had just been taken over; and the Hull laboratory had been taken over, though the service there was not yet working. He made it plain that the hospital pathological service and the public health bacteriological service were administratively distinct, although in practice they would doubtless work very closely together, and that—wherever possible there would be one pathological centre for a whole district to which the general practitioner could send his specimens and go for consultation. How far the hospital pathological service would develop on domiciliary lines he could not say. The public health pathological service did not touch on treatment, nor interfere in any way with the general practitioner's handling of the case.

It was pointed out that occasionally there was difficulty of access of general practitioners to the pathological service in hospitals, but Prof. Wilson replied that, while he could not speak for the hospital service, on the public health side general practitioners were welcomed and were perfectly free to consult with the laboratory. He added that there had been no serious competition between the two branches of the service as regards staff, and as soon as the National Health Service was in being with presumably one general salary scale for pathologists and one scale for technicians, there would be no rivalry of any sort.

Prof. Wilson was asked about the prevention of whooping cough. He said that a whole-time worker was organising special vaccination trials. Whooping-cough vaccination had been reported on very favourably in the U.S.A. It was now being tested out in this country with one or two of the American vaccines and other special vaccines. Trials were being made in North London, at Wembley and Tottenham, and also at Manchester and Leeds. But it was an extraordinarily difficult task of investigation to make it was to be properly controlled, that is to say, if the vaccinated and control groups of children were to be perfectly comparable in every respect. They were proceeding satisfactorily. They were trying to make a proper bacteriological diagnosis of every case of whooping

<sup>1</sup> Sect. 17. "The Minister may provide a bacteriological service, which may include the provision of laboratories, for the control of the spread of infectious diseases, and the Minister may allow persons to make use of services provided by such laboratories."

cough. Post-nasal swabs, obtained before the "whoop" started, were very valuable, and special transport for such swabs, as well as for other specimens, was being considered so that they would reach the laboratory on the same day as that on which they were taken if possible, and might be reported on next morning.

A cordial vote of thanks was accorded to Prof. Wilson, who promised to do what he could to circulate to members of the profession a list of centres—necessarily incomplete at present—where specimens might be collected.

## BIRMINGHAM INSURANCE COMMITTEE

### WEEK-END ROTA ARRANGEMENTS BY PRACTITIONERS

*The following notice has been issued by the Birmingham Insurance Committee to local insurance practitioners concerning the formation of a rota of practitioners available for the treatment of insured patients during week-ends.*

Practitioners desirous of entering into arrangements to provide for a rota being formed of practitioners who would be in attendance at their surgeries on Saturday evenings to provide treatment for the insured persons included in the lists of all the practitioners forming the rota for the district, and to provide all emergency treatment required by such persons during the period from 3.30 p.m. on each of the Saturdays on which the rota duty shall fall to 9 a.m. on the Monday following, are required to comply with the following conditions:

(a) A rota shall be formed which shall make provision for at least one practitioner included in the rota being in attendance at his surgery or surgeries at the times to be arranged to the satisfaction of the committee on every Saturday evening. The practitioner in attendance shall provide treatment for the insured persons included in the lists of all the practitioners included in the rota (hereafter referred to as the participating practitioner) who shall attend for treatment. During the periods commencing at 3.30 p.m. on each of the Saturdays on which a practitioner shall be in attendance at his surgery under these arrangements and ending at 9 a.m. on the following Monday such practitioner shall visit and treat any of the insured persons included in the lists of the participating practitioners whose condition so requires at any place where the patient may at the time be within the districts in which the participating practitioners have undertaken to visit patients.

(b) Each participating practitioner shall be responsible for making arrangements for a practitioner to act on his behalf when he is prevented from giving treatment personally to insured persons during any of the periods in which he is responsible, in accordance with the rota arrangements, for providing such treatment.

(c) For a period of four weeks prior to any rota arrangements becoming operative a notice giving particulars of the arrangements shall be exhibited in the surgery of each of the participating practitioners and such notice shall be displayed during the continuance of the arrangements.

(d) A notice shall be displayed in a prominent position at the surgery and shall be visible to callers at the surgery of each of the participating practitioners who are not in attendance on a Saturday evening stating the name, address, and times of attendance of the practitioner responsible for providing treatment for the insured persons on that particular evening and referring all callers to the practitioner in attendance.

(e) In cases in which a surgery of any of the participating practitioners who is not in attendance under these arrangements is left unoccupied the practitioner shall make arrangements for all telephone calls to be diverted to the surgery of the practitioner in attendance during the times mentioned in paragraph (a).

(f) If a participating practitioner desires to withdraw his name from a rota his name shall be removed therefrom at the expiration of one month from the date of the receipt of the notice or of such shorter period as the committee may agree.

(g) These arrangements shall only remain operative for so long as the committee are satisfied that an adequate medical service is being provided for the insured persons included in the lists of the participating practitioners, and the arrangements shall be terminated at the expiration of one month from the date of the receipt by the participating practitioner of a notice from the committee terminating the arrangements.

(h) A notice announcing the discontinuance of these arrangements shall be exhibited in a prominent position in the surgery of each of the practitioners who ceases to participate in the arrangements, and such notice shall be exhibited for a period of one month immediately preceding the date of such discontinuance.

(i) Rota to be formed in accordance with the foregoing arrangements shall consist of not less than four practitioners.

The committee have no power to relieve a practitioner from any of his obligations under the regulations or the terms of service and in particular the responsibility which is borne by each practitioner for all acts and omissions of any practitioner acting as his deputy or assistant.

## HEARD AT HEADQUARTERS

### Intraprofessional Courtesy

It is a pleasant courtesy—but not a compulsory ethical requirement—whereby members of the medical profession refrain from charging a fee when attending another doctor or his family. We like to think that in the vast majority of cases the courtesy is appreciated, and, if opportunity arises, reciprocated. Sometimes the doctor who has performed the service is gratified to receive at Christmas a box of cigars or a book token. But from correspondence which has reached this office it appears that sometimes the courtesy is taken too much for granted. A radiologist who writes to us on the subject comments on the sad lack of manners displayed by some professional colleagues. Perhaps he has a special grievance, because, while in many cases the attendance given by a doctor to a colleague or his family may not involve him in actual out-of-pocket expenses, in the case of the radiologist, whose opinion has to be founded on the use of some rather expensive material and apparatus, it may mean, if the examination is elaborate, an expenditure of perhaps £3 or £4. Our correspondent says that he has carried out x-ray examinations on members of doctors' families, and has reported to another consultant, and sent copies of the report to the husband, sometimes making long-distance telephone calls, "but not one in twenty, if that, have expressed the slightest gratitude." This is a very discouraging testimony, and one can only hope that the experience is exceptional.

### Informing the Patient's Doctor

The Minister of Health has at last fallen in with the suggestion made by the Insurance Acts Committee that patients' doctors should be informed of the findings in all cases of mass radiography examination, not merely when something abnormal is found, but when the result is negative. A letter has been sent out from the Ministry to all the authorities operating mass radiography units to the effect that the Ministry considers it desirable that all persons whose chest condition is found to be normal on examination should be individually notified, to that effect for the information of their own doctors should they have occasion later to need medical attention. A specimen card has been prepared on which it is stated that "Your x-ray film is satisfactory and no further attendance is required," followed by the injunction to keep the card carefully and show it to your own doctor if you have occasion to require any medical attention from him. It will be noted that the information goes to the examinee, not to the doctor direct. On another matter the Minister has not seen fit to give way. The committee had requested that the patient's own doctor should be given an opportunity of arranging for examination by a specialist in all cases where the regional medical officer considered that a second opinion was desirable; but the Minister still considers that it is not practicable to adopt this suggestion during the limited time that the present National Health Insurance Scheme has to run.

### Patients' Occupation

The Ministry of National Insurance is asking the co-operation of general practitioners in stating on the medical certificate the occupation of the patient. As the Chief Medical Officer of the Ministry told the Insurance Acts Committee, occupation is a primary factor in morbidity, and some useful information might be gathered from statistics of occupations of people treated for both major and minor illnesses. But it soon became evident in discussion in the committee that, while doctors may quite readily accede to this apparently simple request, the matter is hedged about with difficulties. Occupations are of infinite variety and many of them have curious technical descriptions. Even in a single trade there are enough separate occupations to cause con-

fusion. We were told, for example, that "cider maker bottle-mucker" is a well-recognized occupation in the Potteries. In Lancashire we have the "flicker," which may have a different connotation in other parts of the country. The Ministry should provide a schedule of occupations, so that it would be sufficient to designate an occupation according to that schedule. Moreover, it is surely not so much the occupation which is concerned in morbidity as the conditions under which the occupation is carried on. What is the use of saying that a patient is a clerk? The important thing is to know whether he is employed in a decent office or in one of those underground unhygienic warrens which are still too common even in the City of London.

### Agenda

When the members of the General Practice Committee of the Association assembled for the first meeting of the new session recently, encouraged by the praise which the Annual Representative Meeting had extended to them—the only standing committee ever to get a vote of thanks—they needed all such fortification in view of the agenda confronting them. The main agenda consisted of 49 closely typewritten foolscap pages, containing 51 separate items of business, each of them highly detailed. Another document added a further 19 pages. There must have been 40,000 words for them to assimilate, enough reading matter to occupy the whole of the journey of the member who had to cover the longest distance—from Glasgow. Of the main agenda 24 pages were occupied with matters arising out of the minutes of the previous meeting. Then there were 15 resolutions from the Representative Body which had been referred to the committee. One item alone—the remuneration of medical officers to emergency training colleges for teachers—spread itself over 6½ pages. A dispute between one of the Branches of the Association and the National Union of Mine-workers over miners' contributory schemes for medical attendance on dependants occupied another 3½ pages.

### TRAVEL ABROAD FOR HEALTH

The recent currency restrictions of the Foreign Exchange Control present a considerable problem, and they will affect sanatorium beds in this country as well as the patients who wish to undergo treatment in Switzerland. It would appear that restriction is inevitable for those who want to travel abroad for health reasons and whose lives are not in danger; but for those who are recommended to go to sanatoria in Switzerland for early treatment of tuberculosis it is a different matter.

About 500-1,000 patients suffering from tuberculosis go annually from the U.K. to Switzerland, where the facilities are adequate and the waiting lists are not unduly long. Patients admitted to Swiss sanatoria do not have to wait more than one or two months after application. These patients, if unable to go to or remain in Switzerland, and if in need of sanatorium treatment, will inflate the already overcrowded waiting lists in Britain, where in some areas nine to twelve months elapse before admission.

The main difficulty is the selection of cases for overseas treatment. The Foreign Exchange Control have made provision for certain cases, but the method of certification is ambiguous. Two conditions must state on a special form that the patient's life is endangered if he or she does not go abroad forthwith. To remain abroad, for a period of so many weeks. This is unsatisfactory, for some would hold the view that the life of any patient suffering from tuberculosis is endangered. But the certificate suggests that only those *in extremis* should be allowed to proceed abroad, yet those cases would be most unsuitable to travel.

The choice, apart from humane considerations, is between allowing the early cases, who under treatment will become economic assets to the country, to go abroad, and risking their becoming a constant liability by keeping them in Britain. It is clearly impossible to provide at short notice a sufficient number of sanatorium beds in this country to accommodate those patients who would in normal times go overseas. If patients are to be allowed to go at all, and from every point of view it is desirable that they should be, their cases should be submitted to a board specially appointed for discrimination.

## Correspondence

### Suspension of Basic Petrol

SIR,—When it is found that some austerity measure is particularly unfair to a certain class of people steps are usually taken to exempt them—for example, cheap tobacco for old-age pensioners, and extra bread and cheese for agricultural workers, etc. The loss of the basic petrol ration affects our profession more than anyone else. It is undeniable that we work longer hours than most people, and are always on call for our patients, so that when we take a few hours of leisure we use our cars to enable us to return with the least possible delay.

Without a basic petrol ration many doctors will be unable to have any recreation, and I hope that the Association will use its influence with the Government to restore to us our basic ration on the grounds that it is a greater hardship for doctors than for the rest of the community.—I am, etc.,

Woburn, Bucks.

WARREN A. BARNES.

SIR,—All through the war doctors paid taxes for their cars as if they were still "private" motorists. The allowance of the small basic ration made it possible for us to imagine once again that our taxation was at least partly justified. If our cars cannot be used at all for any but professional work, how has the Government the face to soak us in taxation, and why are we such softies as not to protest? Even the insurance companies showed appreciation of the situation, but the Government's ways are very hard. If we were using our cars for pleasure alone we could lay them up and save a good deal of money, but we can't, so we are "had" both ways.

As some of your other correspondents have remarked, it was painful to watch the flimsy protests allowed to obtain petrol for some people during the war, while we might have almost unwittingly been judged "of infamous conduct." We don't want to see all this happening again. "Fair's fair all the world over."—I am, etc.,

Coldingham, Berwickshire.

F. O. TAYLOR.

SIR,—With reference to the suspension of basic petrol, I feel that the strongest possible action should be taken by the Association to get this restored to doctors, the elderly, and those in scattered districts. With regard to doctors, no man works in such depressing circumstances. He is constantly in association with disease and death. Unless he has some outlet to counteract this depression both his health and his work must suffer.

In this area during the past two or three years two men in the fifties and sixties have had to give up owing to disease, and two have had periods of absence from their practices, also owing to disease. To this must be added the sense of frustration, as the measure is useless as a means of meeting the crisis.—I am, etc.,

Handley, Salisbury.

G. BAYNTON FORGE.

### National Health Service

SIR,—We have now been negotiated into a national State health service assumedly with the consent and the satisfaction of the majority of the medical profession. What astounds me is that two negotiating parties have agreed to buy and sell goods and/or services without any settled financial considerations as far as we know. It has been agreed that some time in 1948 every man, woman, and child will be a State patient, and every medical man will be a State doctor if he wishes to earn a living by his profession. We are now in the "closed shop."

Those of us who have bought, are buying, or have built up practices, which are probably our only capital assets, have not the foggiest notion of what is to happen to these assets. Are the people who have negotiated us into this condition to be the people who will negotiate our terms and conditions?

After 35 years, two wars, and a Spens Committee a capitation fee which started at 7s. in 1912 has been raised through struggles and stages to 15s.—a figure which, according to the Secretary of the B.M.A., has met with the general satisfaction of practitioners and has been negotiated without prejudice to future arrangements. With all due deference to the knowledgeable Secretary of the B.M.A., it is my humble opinion that it does prejudice future

arrangements, for, as Mr. Lloyd George used the old club figure of 4s. for his basis of the capitation fee of 7s. in 1912, it is all what used to be Lombard Street to a halfpenny orange that the 15s. agreed in 1947 will be used as the basis of remuneration for State G.P.s in 1948. Taking all things into consideration and comparing the 7s. of 1912 or, if you like, the 9s. of 1938 (which was a grossly inadequate figure), the recently negotiated figure of 15s. is shillings below what in fairness it should be. We are the only utility workers in the country to-day who are and have been gallantly doing our best, and we are getting a "raw deal."—I am, etc.,

St. Osyth, Essex.

R. E. CLARKE.

SIR,—The delay in putting to the profession the results of the negotiations with the Minister can now, after so long, only be due to one of two causes: (a) The proposed National Health Service is being quietly shelved—far too prudent a step for a spendthrift Government in spite of the cost and the economic condition of the country. Such a step, moreover, would at the approaching general election lose the votes of so many people dazzled by the idea of "free" medical attention ("What, still another broken promise!"). (b) The Minister, having announced that the Act will come into force next July, is astutely holding things up so that he can invite us to sign on the dotted line without allowing time for individual and collective consideration.

Yes, we know he has promised it, but what on earth does that matter? "Infiltration" has already proceeded apace. Our position is very nearly surrounded and is beginning to crumble.—I am, etc.,

Alesley, Bedfordshire.

M. L. FARMER.

### Working Hours in the N.H.S.

SIR,—Dr. John F. Flanagan (*Supplement*, Sept. 20, p. 74) and others who support nationalization of medicine are trying to make us believe that there will be less work under such a scheme. In fact there would be much more work and probably less workers. How then can this "calling" be any lighter? The public (and ourselves when we chose the career) knows our job is a trial of patience and tiring in many ways.

It is up to groups of doctors through the B.M.A. or otherwise to arrange the five-day week, or at any rate shorter hours. If they do not choose to do this, then it is their own fault. We do not need a further example yet of nationalization after the 1947 debacle.—I am, etc.,

Newquay, Cornwall.

JOHN P. O'SHEA.

SIR,—In the *Journal* of March 22 (p. 391) you kindly published a letter of mine under the heading "An 84-hour Week." There now appears to be a belated realization that a 24-hour day is envisaged for general practitioners.

It is suggested that an emergency night service scheme, similar to the one in the Danish State Medical Service, be incorporated in our Service. This night service is welcomed by doctors and patients alike in Denmark, would be so here, and would go a long way to answer the requirements of your many correspondents on the hours of work under the N.H.S.—I am, etc.,

London, S.W.6.

G. ROSEMONT.

### Working Day in the Services

SIR,—As another under-employed medical officer I write to underline and add to previous comment on this subject. Not even in more than a year's service have I had a full day's work; my average for work of a purely professional nature is 1½ hours per day, with perhaps thirty minutes for paper work. This of course is spread throughout the day and interferes with any secondary industry I might care to develop. I share this work and my consulting-room with a colleague, for whom apparently no work can be found at present. We realize that we are serving the need to "maintain establishment"; we also feel that at the same time we are supporting a top-heavy structure of administrative organization.

Within this organization restrictive practices are at work. I quote from a document recently issued to me: "Under no circumstances will routine pelvic examination be carried out other than by a Specialist Gynaecologist." Too often, when specialists' advice is sought, the Service mind shows itself occupied with the problem of disposal rather than treatment; too

often in simple matters no treatment can be undertaken "until the medical documents are forthcoming."

Now, I have no grievance against conscription. It is eminently reasonable that those of us who were fortunate enough to continue study and qualify in wartime should take the place of men who have served far longer than we. I merely claim that my time and such little skill as I have are being unnecessarily wasted. If this is a foretaste of a full-time health service I shall probably take my professional appetite elsewhere.—I am, etc.,

FL./LIEUT., R.A.F.V.R.

### Buying and Selling of Practices

SIR,—As I see it the subject of continuing the buying and selling of medical practices has reached the height of nonsense in medicine that "Adam's navel" attained in the realm of religion. I understand that in the forefront of the matters under negotiation with the Ministry is this subject. Should the negotiators succeed in their object most of the present generation of practitioners will find that they have become their own executioners.

Look at the position. In round figures about 20,000 doctors out of a total of 60,000 after being appointed would each have to buy, or hold, that job at a cost of £3,000 to £6,000, a sum not only dead for the remainder of his career but the interest on which could not be deducted for income tax purposes (of course borrowed money would carry a rebate). An even more serious position is involved in that the paying off of this debt would be well-nigh impossible on projected incomes, particularly with high income tax, exorbitant car and house prices, etc. Would it not seem prudent for a young man to seek employment among the more privileged 40,000? Or is there some hidden glamour in G.P. which compensates for the financial strait-jacket?

Again, take the question of distribution of doctors. Where there is a surplus a doctor retiring would not be replaced. How would he be bought out? Or take the reverse case of additional doctors being introduced to an area. From whom would they buy? Then there is linked up with this last point the present shortage of doctors. It is estimated that an extra 30,000 will be required to work the N.H. scheme. There is little doubt that a majority of these would be essential for G.P. Now if we assume even 10,000 introduced, that would mean the capital values of the existing 20,000 practitioners would be reduced by at least one-third in the next ten years, since we are working in a fixed economy—i.e., unless some genius devises a method of bartering "capites." Apart from this devaluation, the present dispensation is hardly encouraging with regard to the availability of several thousand pounds for such a risky investment. It will be obvious that the proposition works equally unfavourably for both seller and purchaser.

Now, it is contended that buying one's practice gives greater independence. I cannot see this. I can see that without full co-operation of the Executive Council the acquisition of capital after a sale could be a very risky business, and it seems too much to expect the Council to act as a transfer agent. There is another aspect which scarcely enhances the vaunted independence: suppose differences arose with an Executive Council, would the fact that several thousands of pounds were at stake make for greater freedom?

In the light of this reasoning what would be achieved by purchasing a medical practice? Certainly not ownership, since control is vested in the E.C., and certainly not freedom. After an essentially clumsy, meaningless, and expensive procedure the unfortunate doctor would only have provided for his own neck a millstone. Since the question under consideration here holds such a prominent place in negotiation there must be another side. A presentation of this side will be greatly appreciated, especially as many doctors are beginning to feel that it would be more reasonable to negotiate acceptable terms for Government purchase.—I am, etc.,

Southport.

S. H. STEWART.

### Compensation for I.M.S. Officers

SIR,—The *British Medical Journal* has reported in some detail the tributes which have been paid to the retiring Indian Medical Service. Kind words are, however, not enough, and all of my colleagues with whom I have been in contact consider that the terms of "compensation" offered to the I.M.S. are ridiculous. Only a small number of officers qualify for the maximum of £6,000, and these are those officers who enlisted shortly before the war. Many in their forties will qualify for less than half this plus a small pension, and if £2,500, which they could draw under existing rules, is deducted from this the net compensation becomes very small indeed. Furthermore, as "Also I.M.S."

points out (Sept. 13, p. 66), the cash grant when paid is attached to a string and may be withdrawn if the officer accepts service under the Crown, whatever the definition of this.

No doubt the British Medical Association has reasons for the apparent delay in representing the matter to the Government, but the members who are affected would like to be convinced that there have been strong reasons for not opening at least preliminary negotiations before this, and it would seem that greater publicity could have been given in the *Journal* to the complete absurdity of these terms and to the fact that no separate scale was drawn up for medical personnel. It is true that most of the medical officers affected will ultimately be able to find appointments or practices, but no scheme is in existence at present to help them, and they are left entirely to their own devices and need fair compensation. It is presumed, however, that, since the Government retains an interest in the compensation paid, it will not reasonably be able to claim that the terms so hastily announced are final.—I am, etc.,

I.M.S.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*County Borough Councils.*—Barnsley, Barrow-in-Furness, Gateshead.

*Metropolitan Borough Councils.*—Finsbury, Fulham, Hackney, Poplar.

*Non-county Borough Councils.*—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallsend.

*Urban District Councils.*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

*Scottish Burghs.*—Motherwell, Wishaw.

## Association Notices

### Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

(1) The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

(2) Any member of the Association who is engaged in general practice is eligible to compete for the prize.

(3) The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not therefore be omitted when it bears directly on their facts, their interpretations, and their conclusions.

(4) Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual General Meeting of the Association to be held in 1948.

(5) No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prize-winner in any year is not eligible for a second award of the prize.

(6) If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay, the decision of the Council on any such point shall be final.

(7) Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

(8) The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

(9) Inquiries relative to the prize should be addressed to the Secretary.

### Nathaniel Bishop Harman Prize

The Council of the British Medical Association is prepared to consider a first award of the Nathaniel Bishop Harman Prize in the year 1948. The value of the prize is approximately £100.

The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

Essays must be forwarded to reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual Meeting of the Association to be held in 1948. Inquiries relative to the prize should be addressed to the Secretary.

CHARLES HILL,  
Secretary.

### B.M.A. LIBRARY

The Association's Library is to be transferred from its present accommodation in the main building at B.M.A. House to the first and second floors of the Garden Court wing. To facilitate the removal the Library will be closed from 12.30 p.m. on Saturday, Nov. 1, until 9.30 a.m. on Monday, Nov. 17.

### Diary of Central Meetings

OCTOBER

29. Wed. Council, 10 a.m.

### Branch and Division Meetings to be Held

**HYDE DIVISION.**—At Hyde Municipal Offices, Wednesday, Oct. 15, 8.30 p.m. Dr. T. H. Chadwick: Anaesthetics in General Practice.

**NORTH OF ENGLAND BRANCH.**—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, Oct. 16, 7.15 p.m., Clinical Demonstration by Dr. W. G. A. Swan: Thyrotoxic Heart Failure; 8.45 p.m., Address by Dr. C. C. Ungley: Neurological Disorders in Pernicious Anaemia.

**WINCHESTER DIVISION.**—At Royal Hotel, Winchester, Wednesday, Oct. 15, 8.15 p.m. Third Annual Medico-Legal Dinner, Address by Dr. Donald Teare: Forensic Experiences.

General practitioners of West Bromwich, Staffs, have arranged an off-duty rota. Twenty practitioners are divided into groups of five, the four men on duty at any given time taking all the calls. The scheme covers week-ends—that is, 1 p.m. on Saturday to 9 a.m. on Monday—and also bank holidays. The Post Office is co-operating by switching over incoming telephone calls to the practitioners on duty.

LONDON SATURDAY OCTOBER 18 1947

## THE AETIOLOGY AND PROPHYLAXIS OF PUERPERAL SEPSIS\*

BY

JOSEPH W. BIGGER, M.D., Sc.D., F.R.C.P., F.R.C.P.I.

*Professor of Bacteriology and Preventive Medicine, Trinity College, Dublin*

As this Congress is being held to celebrate the two-hundredth anniversary of the foundation of the Rotunda Hospital it is not, I hope, inappropriate to attempt to correlate the battles in the long war against puerperal sepsis with the history of the hospital. I propose to divide the two hundred years of the hospital's existence into four periods each of half a century.

The first half-century, 1745-95, presents a melancholy succession of epidemics of childbed fever alternating with brief interludes during which the prevalence of the disease was endemic rather than epidemic. In founding a lying-in hospital, Mosse was trying a more dangerous experiment than he realized. Childbed fever existed in the homes of rich and poor alike in the eighteenth century, but it was not then a very prevalent condition. When the attendants were aged wise women, with an amateur rather than a professional status and a strictly limited clientele, the danger of transfer of infection from one woman to another was slight and epidemics were unlikely to occur. Mosse's plan of herding in one building a number of parturient women and entrusting the supervision of their deliveries to professional midwives had inherent in it the seeds of disaster. So long as no case of childbed fever occurred all was well, but a single case had as its almost inevitable sequel an epidemic.

The rise of the man midwife was in itself responsible for an increase in the number of cases of puerperal sepsis. The man midwife undertook the care of a far larger number of labours than did the woman, and to the risk of transferring the seeds of sepsis from uterus to uterus he added the further risks of transferring by his hands to the birth canal of his patient these seeds derived from other fertile nurseries—wounds with their "laudable pus," droplets from the throats of scarlet fever patients, corpses in the anatomy room of the medical school. The wonder is not that puerperal sepsis was constantly present in the Rotunda, as it then was in every other lying-in hospital, but that these institutions did not acquire an even more evil reputation and that they and their staffs escaped from the fury of the mob, incensed at the slaughter of so many innocents.

In the next half-century (1795-1845) two remarkable Masters, Labatt (1814-21) and Collins (1828-33), stand out above the others. They sought, not entirely unsuccessfully, to combat the disease by such limited degree of isolation as was available, by scouring of furniture, by washing and stoving of bedding, by fumigation of wards, by applications

of chloride of lime, and by whitewashing. They anticipated Holmes and Semmelweis in suspecting that puerperal fever was infectious, that infection was conveyed from the woman suffering from puerperal sepsis to the healthy parturient woman, and that the transmitting agent was far too often the hands of the doctor.

The third half-century, 1845-95, started badly. Reactionaries such as Denham (1861-8) and Johnston (1868-75) opposed the new ideas of Labatt and Collins and of Holmes and Semmelweis, but slowly those ideas spread, and when in 1879 Pasteur dramatically demonstrated the cause of childbed fever as "chapelets en grain," the time was ripe and a new era was born. Pasteur inspired Lister, and the third half-century ended nobly in the Rotunda with Atthill (1875-82), Macan (1882-9), and Smyly (1889-96), under whom, within a period of less than twenty years, scepticism and opposition gave place to a whole-hearted acceptance of Listerism, and the antiseptic era reached its peak.

The fourth half-century (1895-1945) brings us almost up to to-day. In no previous half-century had similar discoveries been made in aetiology, therapeutics, and prophylaxis. So numerous were the advances that it is difficult even to catalogue them. At the beginning of this period bacteriologists had largely accepted the streptococcus as the cause of puerperal sepsis, but it was hard to keep one's faith when streptococci were so frequently present without sepsis. With Schottmüller's application of culture on blood agar to the differentiation of *Str. haemolyticus* from *Str. non-haemolyticus* a real advance was made. Now all was well: puerperal fever was due to *Str. haemolyticus*. But doubts again appeared. A haemolytic streptococcus could be cultivated from the lochia of a woman who was certainly not suffering from puerperal sepsis, who was not even morbid. Further subdivision of the haemolytic streptococci was urgently required. Fermentation of carbohydrates was used by many workers, including myself, but without either satisfaction or enlightenment. Then serological methods, for which credit must be accorded to Lancefield (1928, 1933) and Griffith (1926-8), were introduced, and almost at once the dark places were illuminated. We now group the haemolytic streptococci by Lancefield's method and recognize an organism of group A as the *Streptococcus pyogenes*, the main cause of puerperal sepsis. By Griffith's technique we subdivide *Str. pyogenes* into more than a score of types, and so, not rarely, it is possible to trace to its source the streptococcus responsible for a case of sepsis.

In therapeutics, vaccines and antisera had their day: but only a few enthusiasts had faith in them, and both are now

\*A paper read before the International Congress of Obstetricians and Gynaecologists, held in Dublin, July 7-11.

discarded. In 1935 came Domagk's "prontosil," to be followed hot-foot by the polyonymous sulphonamides. In 1929 Fleming discovered and described most of the properties of penicillin, but it was only after ten years that the greatness of his discovery was realized. It required the vision and persuasiveness of Florey and a world war to make available the first, and still the greatest, of the antibiotics.

In the field of prevention progress was steady if not spectacular. The application of Lister's antiseptic methods to midwifery ended for all time the major epidemics of puerperal fever characteristic of the practice of the Rotunda, as of other lying-in hospitals, in the eighteenth and the early nineteenth century. The combination of antiseptics and asepsis prevents the transfer of infection from patient to patient by the hands or instruments of doctor or nurse. But sporadic cases still occur and, much more rarely, small epidemics. Once the infectivity of puerperal sepsis had been realized the transfer of the causative organism from the uterus of one woman to that of another could be stopped relatively easily. Comparatively little effort yielded a large return, but puerperal sepsis did not cease to exist.

The uterus is a hollow viscus in relatively free communication with the exterior at a situation on the surface of the body where bacteria of various types abound. After childbirth it contains in its interior blood clot, an excellent nutrient for bacteria, and this is in contact, at the placental site, with underlying tissue temporarily deprived of the protective covering of epithelium. The uterus itself and the surrounding parts have recently suffered various insults incidental to the process of childbirth. The fire is set: only a spark is required to start a conflagration. Others who follow me will deal with the nature of the conflagration and how it may be extinguished. My concern is with the spark which may kindle the fire, its nature and source, and how it may be kept at a safe distance.

The most important cause of puerperal sepsis to-day is *Str. pyogenes*. There is little doubt that the same organism was responsible for the epidemics of the eighteenth and nineteenth centuries, but the sources have changed. Then the main source was the uterus of the septic patient. Other sources were septic wounds, sore throats, erysipelas, and impetigo. Transmission was accomplished, all too easily, by the unwashed hands of the doctor. Now conditions are entirely different. There are far fewer cases of puerperal sepsis to act as sources of infection, the obstetrician's hands are much less often contaminated with *Str. pyogenes* from other infections, and the barriers of washing, antiseptic lotions, and rubber gloves are interposed to prevent the transfer of the organism to the genital passages of the woman at the time of childbirth. When a group of cases occurs in a ward at intervals of a few days there is a presumption that the infection has been transferred from one to the other—not usually, it should be said, owing to a lack of cleanliness of the obstetrician's hands but to some less obvious break in the essential barrier between patient and patient. The ideal method of avoiding case-to-case transfer of infection is to provide a separate room for each woman admitted. The next best is prompt isolation of any woman on the first suspicion of sepsis: morbidity demands isolation. But there is a period, possibly only of hours, before sepsis suggests its presence by morbidity, and during this period *Str. pyogenes* is multiplying in and being discharged from the affected uterus. We cannot make a diagnosis of sepsis early enough to avoid all risk of spread, so we employ additional defences. These are isolation, as complete as local conditions permit, and the making over to each woman admitted of a set of all essentials of toilet and

hygiene. The dangers of the communal bed-pan are lessened by disinfection: they are still further reduced if a bed-pan is reserved for each woman and if it is disinfected.

Limitation of vaginal examination, a strict ritual of hand and glove preparation, the wearing of gowns, and disinfection by steam of all instruments eliminate relatively easily the major risks of introducing streptococci into the birth canal.

At one time it seemed possible that puerperal sepsis would become extinct, but the curve showing its prevalence, which declined sharply as a result of the application of antiseptic and aseptic precautions to midwifery, failed to reach the zero line. There is a hard core of puerperal sepsis, and only by the greatest exertions can this hard core be reduced. An explanation of the sporadic case of puerperal sepsis which for a time appeared adequate was that the source of infection was endogenous—that is, that the *Str. pyogenes* was present in the vagina before the onset of labour and that from that situation it spread to the then highly vulnerable uterus after delivery. Some twenty-five years ago this seemed reasonably probable. Support for the theory was given by the finding of haemolytic streptococci in the flora of the vagina, both before and after labour, in from 3 to 6% of parturitions. But when our fumbling attempts to group haemolytic streptococci on the basis of fermentative capacities were replaced by surer serological methods and *Str. pyogenes* was accurately delimited, it was found that the haemolytic streptococci of the vagina were never, or practically never, of group A. The journey of that organism to the uterus is a longer one than from the adjacent vagina.

The proximity of the anus to the vulva suggested the possibility of infection of the uterus being derived from the faeces. This actually occurs, but not in the case of *Str. pyogenes*. This organism never gives rise to the carrier state in the intestine, and only very infrequently does it occur there as a pathogen.

### Throat Carriers

We now know that the main reservoir of *Str. pyogenes* is the human throat. There it flourishes as a pathogen, producing scarlet fever or simple sore throat, and, still more commonly, there it lurks as a saprophyte on a mucous membrane which appears slightly, if at all, abnormal. The rate of throat carriers of *Str. pyogenes* varies greatly with time, population, place, and season, but a conservative estimate is that some 5% of a group of people harbour *Str. pyogenes* in their throats. Having traced the chief organism of puerperal and, indeed, of all types of sepsis to the not obviously abnormal throat, little imagination is required to picture its transfer to the uterus. Every time we cough or sneeze, shout or speak loudly, we spray out from our mouths and noses thousands of small droplets of saliva and mucus. If the sprayer is a throat carrier of streptococci these organisms leave his body in enormous numbers in the droplets. Good manners demand that, when coughing or sneezing, the hand or handkerchief be held before the face, and so the hand is contaminated directly from the droplets or indirectly from the handkerchief or the pocket into which it is put. It may be further contaminated by contact with objects on which droplets have fallen.

The hands of the doctor are, as we have seen, usually adequately prevented from becoming the transmitting agent of the streptococcus; but there are other hands, and especially there are the hands of the woman herself. If she is a throat carrier of *Str. pyogenes* her hands may easily transfer the organism to her vulva: but even if she is not a carrier her hands may transfer the organism, picked up from the air, from bedding or clothing, or from the

ther source. The other hands to be considered are those of the nurse. When carrying out treatment involving contact with the genital tract they should be, and presumably be, just as carefully prepared as are those of the doctor; but the nurse has many duties—dressing and washing the patient, making her bed, handling her bed-pan, and adjusting the vulval pad—and some of these involve either direct contact with the vulval region or contact with something which later makes such direct contact.

The hand has been dealt with first because it is the main vector of streptococci on their journey from the mouth and nose to the uterus, but transfer may occur in other ways. Few doctors or nurses sneeze upon the vulvae of their patients, and so direct transfer by droplets from throat to genital tract is rare, but direct transfer from throat to throat does occur. A carrier, whether patient, doctor, nurse, or visitor, may introduce *Str. pyogenes* into a ward, where it may establish itself in the throats of several inmates, each of whom constitutes a fresh focus of infection. Sooner or later droplets fall to the ground, the bed, or other surfaces, where they dry and enrich the dust with their streptococci. *Str. pyogenes* is usually considered to be a rather delicate organism, but when dried in dust it can survive for a period to be measured in weeks rather than days.

#### Droplets and Dust

The dangers of droplets and dust can be and should be reduced by the wearing of adequate masks and by the application of dust-controlling oils to floors and bedding. Only exceptionally should it be necessary to resort to disinfection of the air in a ward by ultra-violet radiation or, more simply and economically, by disinfecting mists. Valuable as these measures are, they come into operation at too late a stage. They seek to limit the diffusion of *Str. pyogenes*, but our aim should be to exclude that organism completely from our wards.

Each person regularly visiting a ward in a maternity hospital should have a throat swab examined for *Str. pyogenes* every week. If gentian violet blood agar is used it is possible, within 24 hours, to isolate streptococci from a throat and to identify those which are haemolytic even when very few are present. All found harbouring these organisms should be put off duty for 24 hours while the haemolytic streptococci are being grouped. If they are of group A—that is, if they are *Str. pyogenes*—the off-duty period should continue until in three consecutive daily examinations the throat is found to be free from that organism. If the streptococcus does not belong to group A the carrier presents but a slight danger and may be returned to duty.

This control should be applied to all members of the staff, whether doctor, nurse, or maid, whose duty takes them into a ward used for women before, during, or after labour. I fully realize how unpopular this would be and how liable it might be to disorganize the usual routine of a hospital; but a carrier of *Str. pyogenes* is such a menace that, in my opinion, eradication of puerperal sepsis will not be possible without it. Since there is an almost universal tendency to regard oneself as indispensable, efforts may be made to obtain a falsely negative result by various subterfuges, which must be rigorously guarded against. The duration of the carrier period may be greatly reduced by local application of a sulphonamide or penicillin. I do not advocate these substances for the prevention of the development of the carrier state.

Casual visitors, who should be reduced to a minimum, present a smaller problem, but still a problem. They should wear masks and gowns and should not be allowed to approach the patient too closely. I scarcely dare to advo-

cate that, during the visit of the husband or mother of the patient, a glass screen should be interposed between her visitor and herself and that conversation should be conducted by microphone, but it would be a rash man who would say that such precautions will not ultimately be instituted.

What of the throat of the patient, which we have so far neglected? A *Str. pyogenes* of the same type has so often been found in the throat and septic uterus of a patient as to suggest that in such cases the uterus became infected from the throat. The alternatives that the throat was infected from the uterus or that both were infected from another person cannot, however, be overlooked.

*Str. pyogenes* in the throat of a woman at childbirth constitutes a danger to her own uterus and also to the uteri of other patients. That danger may be guarded against, in part, by bacteriological examination of throat swabs, but an obstetrical hospital is often an emergency hospital in that the patient is not always, or not even usually, admitted sufficiently long before labour to permit the bacteriologist to report whether she is a carrier of *Str. pyogenes* or not before delivery. The history of the Rotunda could furnish details of delivery occurring at every stage of the patient's journey from her home to the labour ward. The ideal arrangement is, as I have already stated, a separate room or cubicle for every patient. The second best is isolation, as complete as possible, from other patients of all new admissions until they have been found not to be carriers of *Str. pyogenes*. A patient found to be a throat carrier of *Str. pyogenes* should be isolated completely from all other patients and provided with her own nurses for as long as she is a carrier. Local treatment of her throat should be promptly instituted, and if she is still a carrier at the onset of labour her uterus should be safeguarded by systemic administration of penicillin.

The only other precaution to be considered is the general prophylactic use of chemotherapy. Sulphonamides have been used to some extent for this purpose, but the results have not been encouraging. Penicillin has not, so far as I am aware, been extensively reported upon as a prophylactic. I certainly would not advocate its routine use, but, if a case of puerperal sepsis should occur in a hospital, I believe that every woman admitted should receive systemic penicillin from the onset of labour until five days after delivery. I do not believe that the introduction of antiseptic substances into the vagina before or after delivery should be required for the prevention of puerperal sepsis due to *Str. pyogenes*. The advisability of such prophylactic methods as a guard against other organisms will be considered later.

Up to the present I have dealt with puerperal sepsis as if it were a specific disease like scarlet fever, due always to a haemolytic streptococcus of group A. I have done so because the epidemics of the past and the majority of cases of what I may call classical puerperal sepsis of to-day are due to this organism. But other bacteria must also be considered.

Let us deal first with those organisms so commonly found in the vagina ante partum as to constitute its normal bacterial flora. The most numerous of these are lactobacilli and anaerobic streptococci. It is probable that these came originally from the faeces, from which they may again be reintroduced from time to time, for they readily adapt themselves to the conditions present in the vagina. The lactobacilli may at once be exonerated. So far from being dangerous, by their powers of glycolysis leading to acid production they are highly beneficial commensals. The anaerobic streptococci are much less innocent and, indeed, present a special problem which will be considered later.

The richest bacterial flora of the body is found in the faeces, and the proximity of the anus to the vulva makes it obvious that the complete exclusion of faecal bacteria from the birth canal would be quite impossible. Coliform bacilli, so characteristic of the faeces, are but rarely found in the vagina ante partum. Their numbers increase somewhat post partum, but it seems clear that they are merely saprophytic in the lochia and are very rarely, if ever, the primary cause of puerperal sepsis, although by their presence they may have some enhancing effect on the virulence of other organisms.

Disease, and indeed disease of severe and often fatal type, may be produced by *Cl. welchii* and *Cl. tetani*. These organisms may be derived from the faeces, but, since their highly resistant spores have been found in cotton-wool and in sanitary pads prepared from it, an obvious alternative source of infection is available. Danger from this source must be guarded against by thoroughly efficient heat sterilization of cotton-wool used in connexion with midwifery. These clostridia have slight invasive power and present little danger provided there is no retention of lochia, no necrosis of tissue, and no extensive multiplication of other bacteria which might render conditions suitable for their development.

The faeces may be the source of many other bacteria sometimes to be found in the vagina ante partum and, in still larger numbers, post partum, but even in the post-partum uterus they have little if any pathogenic power—they are mere saprophytes.

It is curious that *Staphylococcus pyogenes*, such an important cause of sepsis elsewhere, is so rarely incriminated in puerperal sepsis. Cases of undoubted infection produced by it are recorded, but much less frequently than its ubiquity would suggest. Midwifery practice cannot ignore this organism, on account of its frequent association with sepsis of perineal lacerations and its marked tendency to cause thrombosis. Its reservoir is the nose, in which, as also on the skin and particularly the skin of the hands, the carrier condition is established. The wearing of adequate masks and of rubber gloves, and preparation of the hands, are probably adequate safeguards against it. *Staph. albus*, so slightly pathogenic as to be regarded as a saprophyte, may be found in the lochia but is not important.

Haemolytic streptococci, other than *Str. pyogenes*, which gave rise to so much confusion before the introduction of Lancefield's serological grouping, have quite often been isolated from the lochia of women who show no evidence of puerperal sepsis. Their pathogenic powers are much more feeble than those of group A streptococci, and in the uterus they usually behave as saprophytes. Occasionally, however, one or other gives rise to serious and even fatal sepsis. Streptococci of these groups show a marked tendency to spread from the uterus to the blood stream, causing fatal endocarditis. Streptococci of groups C and G, like those of group A, are unable to survive long in the vagina, and so in order to cause puerperal sepsis they must be introduced shortly before, during, or soon after delivery. The usual source of both is the human throat, for the organisms are harboured there in the carrier state or as causes of mild tonsillitis. Direct infection from the horse, in which group C organisms cause strangles, is improbable. Streptococci of groups B and D are occasionally found in the vagina, where they can apparently persist as saprophytes, and so have an easy route to the uterus after delivery. Direct infection of the uterus post partum by milk of cows suffering from bovine mastitis, which is caused by group B streptococci, is not a likely accident. Group D streptococci are commonly present in the faeces, from which methods of transfer to the uterus are obvious.

The measures suggested to reduce the dangers of infection by group A streptococci apply to exogenous infection by other haemolytic streptococci foreign to the vagina (C and G) and should prove adequate for the purpose.

### Endogenous Infection

We are now left with the difficult problem of endogenous infection of the post-partum uterus by organisms of the vagina and particularly by anaerobic streptococci and by aerobic streptococci of groups B and D. Again I wish to emphasize the frequency with which these organisms are found in the uteri of women whose puerperium causes their obstetricians not a moment's anxiety. They are not commonly the cause of puerperal sepsis, and in the uterus they usually behave as saprophytes. Only in a small proportion of cases in which they are present in the uterus do they give rise to morbidity, and in only a small proportion of such cases do they actually cause sepsis. Of the two, the anaerobic streptococci are of much greater importance. They are, in fact, second only to *Str. pyogenes* as causative organisms of puerperal sepsis. They are rarely present in the lochia in pure culture in cases of sepsis, but are usually accompanied by other organisms, such as *Staph. albus* or diphtheroid bacilli, which, alone, are devoid of pathogenic power. It may be that the combination of one or more saprophytes with anaerobic streptococci endows the latter with abnormal pathogenicity. While the streptococci are endogenous the other bacteria are exogenous, and thus all the precautions which are effective in excluding bacteria from the genital tract should be of value in reducing sepsis due to endogenous anaerobic streptococci.

Prophylaxis by the application of antiseptic substances to the vagina has been fairly extensively, but not very critically, tried. I am somewhat prejudiced against this method, but some American experiences seem to show that it is of value, and it certainly appears to be safe. If any such application is to be made it should, in my opinion, be made before the onset of labour rather than after. In place of mercurochrome, which has been used for the purpose, I would advise a combination of penicillin, a sulphonamide, and proflavine. The first two are suggested because some of the organisms against which protection is sought are sensitive to one and some to the other. Proflavine is added to deal with bacteria resistant to both. The combination is unlikely to damage tissue and so open fresh portals to infection, but there is a danger that by inhibiting the growth of lactobacilli it may deprive the birth canal of a valuable means of protection.

I do not wish it to be thought that I am a strong advocate of this procedure, and I suggest its use only because we have no other method of protection against endogenous infection. If it is to be used at all, it should be so used as to demonstrate beyond doubt whether it is of value or not. This requires a large series of treated cases with an equal number of strictly parallel controls so as to yield statistically significant figures.

I have attempted to lay before you the essentials of the bacteriology of puerperal sepsis, and I have ventured to make recommendations which might, I believe, reduce still further the present satisfactorily low level of the disease. I propose to conclude with a warning. The continuation and extension of the precautions which have been so successful will in time make puerperal sepsis such a rare condition that obstetricians even of considerable experience will never have seen a case and will tend to regard it as a disease as extinct as cholera. It will then be very hard to maintain, day by day, month by month, and year by year, all the elaborate, time-consuming, and irritating precautions which we now know to be essential and which have given

the victory, but which to the young obstetrician will appear but meaningless ritual. Then there will be a tendency, which it will be hard to resist, to relax some of the precautions, but so long as *Str. pyogenes* continues to exist the throats of the people such relaxation will inevitably be followed by the reappearance of puerperal sepsis, the story of which is reflected in the history of the Rotunda hospital.

## PENICILLIN AND THE TREATMENT OF INFECTED HANDS IN OUT-PATIENTS

BY

FRANK D'ABREU, Ch.M., F.R.C.S.

Assistant Surgeon, Westminster Hospital

CHARLES M. FLOOD, M.B., B.S.

Surgeon Lieutenant, R.N.V.R.; late Acting Assistant Surgical Registrar, Westminster Hospital

AND

HAROLD B. HEWITT, M.B., B.S.

John Burford Carlill Institute of Pathology, Westminster Hospital

Penicillin is widely used in the treatment of the infected hand. It has been employed as a cream or powder for local application, and by direct injection into the theca in cases of suppurative tenosynovitis. In this review of cases treated at the Westminster Hospital it is our aim to assess the value of a method of administering systemic penicillin which can be used on out-patients. Only two of the patients treated with penicillin were admitted to hospital. This was from necessity rather than choice in the first instance, but later, when supplies of penicillin became available, out-patient treatment was deliberately adopted to save blocking ward-pressed bed space.

Eighty-five per cent. of all cases reviewed, and all cases receiving penicillin, were seen and treated by us throughout. In the remainder incision was done by casualty officers, but after-treatment was prescribed by us. This insured uniformity for the purpose of assessment. The cases are considered under two groups: Group I consisted of 168 cases treated without systemic penicillin, and Group II of 17 cases treated with systemic penicillin. Within each group the following types of lesion are differentiated: (1) paronychia and pulp-space infections; (2) tenosynovitis; (3) palmar-space infections.

It is not feasible to give penicillin at four-hourly intervals to out-patients, and it was therefore hoped that a therapeutically adequate serum level might be maintained by very large doses, given morning and evening by intramuscular injections of aqueous solutions or beeswax-oil suspensions. The aqueous solutions produce high serum penicillin levels of brief duration, whereas the wax-oil suspensions produce a lower but more prolonged serum level and were found clinically to be more efficacious. No untoward effects, such as urticarial reactions or marked pain, were noted.

### Diagnosis

(1) Pulp-space infections and paronychia were usually only too obvious, as the average duration of symptoms before the patient arrived at the surgery was six days.

(2) Tenosynovitis was diagnosed by the following criteria: swelling of the whole finger, which was held in a semi-flexed position; great tenderness on pressure over the tendon sheath; and severe pain on attempted passive extension.

(3) Palmar-space infection (middle and thenar spaces) was diagnosed by diffuse tenderness, convexity of the palm overlying the affected space, and gross dorsal oedema.

### Treatment

Palmar-space infections were drained by incising into the web, passing a Spencer Wells forceps into the space, and inserting a corrugated rubber drain deep into the space, to be left in place for three days. In the tenosynovitis cases incision of the tendon sheath was not needed. When the inflammation was secondary to superficial infection the latter was drained by through-and-through incisions, with administration of systemic penicillin in Group II cases. When secondary to puncture wounds, penicillin only was used, without incision. Pulp-space infections were treated by bilateral incision with through-and-through drainage. In most cases of paronychia the entire nail was removed, as attempts to save part of it resulted in slower healing with a distorted nail and nail-bed.

The dressing applied at operation was changed after three days, when any drain was removed; the wound was then dressed with 17½% sodium sulphate and left for four days. Subsequent dressings, if required, were done at intervals of a further five to seven days. Soaking in hydrogen peroxide to facilitate removal of hardened dressings was reduced to a minimum. Some wounds were dressed with gentian violet, soda sulphate and acriflavine, "tulle gras," or penicillin cream, but the impression was that the medication made little difference to the rate of healing. All septic hands were kept in a sling at least until the first dressing was done. Adequate analgesics were given on the first two to three days after incision, but, if incision had been adequate, little was needed after twenty-four hours. Most noticeable was the great relief of local pain on starting systemic penicillin. Patients were instructed to keep the dressings dry and undisturbed. This ideal could not be attained by all of them—for example, mothers of young children. Such patients were instructed to remove the wet sodden dressing and replace it with a clean piece of dry lint or gauze with no ointment of any kind. Otherwise all dressings were done separately from the rest of the surgery cases, with sterile dressings by a "clean" nurse. No patients were discharged until they were able to do full work with either no dressings at all or a dressing of such size that it would not interfere with their manual skill or render them liable to accident due to clumsiness because of the bandage—an important consideration, as many of these patients were skilled workers.

### Results

An analysis of the 168 cases treated without penicillin is given in Table I. The period of unfitness for work is

TABLE I.—Details of 168 Cases Treated Without Penicillin (Group I)

Lesion	No. of Cases	Av. Duration of Symptoms before First Attendance (Days)	Day of Incision after Treatment Started				Average Time Unfit for Work (Days)
			Same Day	1st	2nd	3rd	
Paronychia and pulp-space infections ..	135	6.1	91 (67.4%)	23 (17%)	10 (7.4%)	11 (8.2%)	21.0
Tenosynovitis .. ..	16	5.5	9 (56%)	5 (31%)	2 (13%)	—	17.5
Palmar-space infections .. ..	17	4.6	9 (53%)	4 (24%)	3 (17%)	1 (6%)	16.5

Average days unfit for work, 20.3.

calculated from the first hospital attendance till discharge. The shorter convalescence of the tenosynovitis and the palmar-space infection cases is explained by the fact that, though the lesions were more serious, it was possible to send a man back to work with a strip of "clastoplast" over his finger or palm when it would have been impossible with a dressing on his finger tip.

In the 17 cases in Group II two forms of penicillin were used—the ordinary water-soluble penicillin and a suspension of penicillin in beeswax and oil. Patients in bed were given intramuscular injections of 30,000 units of the former four-hourly. Out-patients were given massive doses, up to 300,000 units, of water-soluble penicillin morning and evening, or 100,000 to 150,000 units in beeswax and oil at similar intervals. Details are set out in Table II. These cases

TABLE II.—Details of 17 Cases Treated With Penicillin (Group II)

Case No.	Lesion	Days of Symptoms before First Attendance	Day of Incision after Treatment Started	Days Unfit for Duty	Treatment with Penicillin (Units)
1.	Pulp infection or paronychia	5	Same day	10	7 × 300,000 W.S.
2	"	5	"	8	6 × 125,000 B.O.
3	"	6	"	7	8 × 150,000 B.O.
4	"	4	1st	4	4 × 300,000 W.S.
5	"	4	Same day	9	4 × 300,000 W.S.
6	"	4	"	8	300,000 W.S.; 3 × 150,000 B.O.
7	Tenosynovitis	6	"	12	6 × 150,000 B.O.
8	"	2	Not incised	3	1 × 500,000 B.O.
9	"	3	"	8	6 × 125,000 B.O.
10	"	3	Same day	10	8 × 300,000 W.S.
11	"	5	"	8	4 × 300,000 W.S.
12	"	1	Not incised	8	4 × 100,000 B.O.
13	"	14	Same day	22	4 × 300,000 W.S. (b.d.) (bed 5 days)
14	Palmar-space infection	4	1st	12	6 × 200,000 W.S.
15	"	2	Not incised	8	4 × 125,000 B.O.
16	"	3	2nd	41	860,000 (30,000 4-hourly) (bed 5 days)
17	"	5	Same day	8	4 × 150,000 B.O.

W.S. = water-soluble penicillin. B.O. = penicillin in beeswax and oil.

received treatment with penicillin because they were clinically more serious than those in Table I. In spite of this the duration of treatment was considerably shorter.

The three cases below are described, as they represent the two extremes in the duration of incapacity. Case 8 was able to return to duty only two days after receiving an unintentionally large dose of penicillin, while the other two patients were away from their work for 22 and 41 days respectively.

**Case 8.**—This was a nurse who two days previously had run a needle through her left index finger. When seen she had every sign of a severe suppurative tenosynovitis of the finger. By an error she received a dose of 500,000 units in beeswax at one injection—five times greater than intended. Twenty-four hours later every sign and symptom had completely disappeared, and two days later she returned to full duty.

**Case 13.**—This was the worst case of tenosynovitis seen in nine months. The patient was a soldier who had complained of symptoms suggestive of a pulp-space infection for a fortnight but had nevertheless been on full duty, including work as a porter at Billingsgate during a strike. He had been carrying crates of fish the night before he was sent to hospital with all the signs of suppurative tenosynovitis. He was ambulant and fit for discharge to light duty after five days in bed, but it was thought wiser to keep him in "protective custody" for a further seventeen days.

**Case 16.**—This patient had a severe palmar-space infection which was almost healed on discharge from hospital to the out-patients' department after five days. Contrary to advice, while still under treatment he returned to his work as a cook and dishwasher with the result that his wound became sodden and re-infected and his convalescence was prolonged to 41 days.

If Cases 13 and 16 are excluded the remaining fifteen cases give an average duration of days unfit for work as follows:

Type of Lesion	No. of Cases	Average Loss (Days)
Paronychia .. .. .	7	9.9
Tenosynovitis .. .. .	5	7.4
Palmar-space infection ..	3	9.3
Total .. .. .	15	8.9

#### Notes concerning Serum Penicillin Levels obtainable with Wax-Oil Suspensions

Serial serum penicillin levels were estimated in one case (No. 13) following a single intramuscular injection of 150,000 units of penicillin in beeswax and oil; these are shown in the Chart. Estimations made at random on other cases conformed with this curve. In one case in which an estimation was made twelve hours after a single injection of 150,000 units the neat serum was found to have no inhibitory power. In a further case (No. 8) a single intramuscular dose of 500,000 units was given: no inhibition was detectable nineteen hours after injection.

Chart showing serum penicillin levels following a single intramuscular dose of 150,000 units of penicillin in beeswax and oil.

It is clear from these few observations that a practically continuous level of penicillin, averaging only 0.08 unit per ml., can be maintained throughout the twenty-four hours by giving late evening and early morning doses of 150,000 units of penicillin in wax-oil suspension. It is to be noted, however, that the peak level obtainable with such a scheme is only 0.32 unit per ml. From the gratifying results achieved in the series of cases here reported it would appear that the need for higher peak levels has not arisen. But it is most necessary to remember that organisms only slightly more resistant than the Oxford staphylococcus would be quite unaffected by the levels obtained with this mode of treatment. Moreover, such levels do not provide a sufficient "head" for the penetration of necrotic tissue. For these reasons the use of wax-oil preparations should be abandoned if no response is apparent at the end of forty-eight hours. It should be noted that, clinically, nearly as good results were obtained with 300,000 units of penicillin in watery solution twice a day. Serum penicillin estimations were not made on cases so treated.

#### Commentary

Since the disability from a septic finger treated without penicillin lasts nearly as long as that ensuing in the average case of appendicitis any form of treatment that will appreciably reduce this time is justified. In the above series the period of disability has been reduced by 56%—from 20.1 days to 8.9 days. Though this series be small, it justifies in our opinion the use of penicillin in all severe or potentially severe cases of septic hands and in all cases needing incision. The dosage will vary with the clinical picture, but the minimum dosage should be 125,000 units of penicillin in oil or 300,000 units of water-soluble penicillin morning and evening for at least forty-eight hours. At the time these observations were begun it was impossible to carry out this as a routine owing to the shortage of penicillin in oil and the expense of massive doses of water-soluble penicillin.

As it is possible to treat these cases in the out-patients' department there is a considerable saving in bed space.

well as in man-hours. Even better results would be obtainable if patients could be seen in the earlier stages of infection. Of the cases detailed in Table I, 65% needed immediate incision; in the three cases in Table II in which penicillin treatment was started less than three days after the onset of symptoms incision was unnecessary. This once again emphasizes the need for early diagnosis of the various infections of the hands and for appreciation of their serious nature.

### Summary

A review is presented of 185 cases of infected hands seen in the surgery of Westminster Hospital—168 treated without, and 17 with, penicillin.

Cases treated without penicillin included 135 of paronychia and pulp-space infection, with an average loss of 21 days' duty; 16 cases of tenosynovitis, with an average loss of 17.5 days; and 17 cases of palmar-space infections, with an average loss of 16.5 days. The average loss of duty for these 168 cases was 20.3 days.

The penicillin-treated series comprised 7 cases of paronychia and pulp-space infection, with an average loss of 9.9 days' duty; 5 cases of tenosynovitis, with an average loss of 9.9 days (excluding Case 13, 7.4 days); and 4 cases of palmar-space infection, with an average loss of 17 days (excluding Case 16, 9.3 days). The average loss of duty in these 17 cases was 10.9 days. If the two unusual cases, Nos. 13 and 16, are excluded, the final average is reduced to 8.9 days—a saving of 56% compared with the non-penicillin series.

On the basis of these results it is suggested that the administration of penicillin in all severe infections of the hand, both in the early stages and after any necessary surgical intervention, should be adopted as a routine method of treatment.

In practice a dosage of 125,000 units in oil or 300,000 units in aqueous solution twice daily has been found adequate.

We are indebted to Mr. G. T. Mullaly, Senior Surgeon, Westminster Hospital, whose enthusiasm and interest made this experiment possible; to Prof. R. J. V. Pulvertaft, who made penicillin in beeswax-oil available at a time when supplies were limited; and to the nursing staff of the surgery for their co-operation in carrying out treatment.

One of us (C. M. F.) is grateful to the Medical Director-General, Royal Navy, for permission to publish.

The President of the Medical Defence Union, Mr. St. J. D. Buxton, speaking at the Annual Meeting on Sept. 16, said that during the preparation by the General Medical Council of a Bill to amend the Medical Acts, representatives of the Medical Defence Union (together with those of the sister societies) had been received by the President of the G.M.C. and a subcommittee. Many of the recommendations made by the Union had been well received, but there was not agreement on all matters. In view of a clause in the Bill allowing appeal to a court from a decision by the G.M.C., the position of any member who had been defended by the Union was somewhat anomalous. In order that he should remain a member during the time allowed for decision as to whether an appeal should be lodged and during the hearing of such an appeal, the Articles of Association would be amended. Speaking of the National Health Service Act, he said that legal representation would be permitted on specified occasions, when practitioners were summoned regarding professional procedure and conduct. The Council periodically had to consider whether the Union could defend members against whom proceedings were being taken by patients in a matter not directly one of professional principle. Although the Council might wish to assist the member, the Union's Memorandum would not permit of the risk being covered by the Union. Hence it was recommended that members should take out a policy with a reputable insurance company to cover injury to patients, not connected with professional affairs, when on the practitioner's premises. Those who read the medico-legal matters in the medical and lay press would be aware of the importance of an action concerning assistants' agreements. He advised any members employing or seeking to employ an assistant, and all assistants who were members of the Union, to seek the Union's advice regarding the wording of the agreement, as the Council had obtained leading counsel's opinion and the Secretary was in a position to submit a suitable clause. With regard to swabs, it was noticeable that the retention of swabs in the pharynx after nose and throat operations had recently been more frequent than in the abdomen.

## RELATION OF ABACTERIAL PYURIA TO REITER'S SYNDROME

BY

G. H. BAINES, F.R.C.S.

Assistant Surgeon, Birmingham United Hospital

Abacterial pyuria has been discussed in several recent papers. Its general features are now well recognized, but its aetiology remains obscure. Probably the most commonly held theory is that it is due to a virus infection.

That Reiter's syndrome might be associated with a sterile cystitis has been known from the first. Later, Colby (1944) described three cases with renal symptoms. His second case is of particular interest, since it demonstrates the development and final resolution of a hydronephrosis. This has often been noticed as a renal complication in abacterial pyuria. In addition one kidney was removed because it was thought to be tuberculous. Section of this kidney showed a thin parenchyma with a dilated pelvis and calices and numerous scattered haemorrhages, but no evidence of tuberculosis. Unfortunately a report of the microscopical appearance is not given, but so far as it goes the condition seems to be similar to that described by Donovan (Moore, 1943) in a similar case later proved to be abacterial pyuria. Cystoscopy in Colby's case showed a diffuse reddening of the bladder. No specific treatment was given and the condition cleared up, but there was a relapse four years later. Prostatitis was present in two of Colby's cases, and an abscess formed and discharged in one. Hollander *et al.* (1945) noted a residual prostatitis in four of his cases.

Joint effusions have been reported in several cases of abacterial pyuria lately. If the cases reported below had come under observation at a time when the urethritis and cystitis were present but before the arthritis developed they would undoubtedly have been classified as abacterial pyuria, not as Reiter's syndrome. It would appear that there is nothing to distinguish the sterile urethritis, cystitis, prostatitis, and pyelitis found in Reiter's syndrome from abacterial pyuria. It has repeatedly been stressed that all cases of abacterial pyuria respond to N.A.B. (Baines, 1947; Moore, 1943; Vassallo, 1946). I have found the same response, so far as the urinary symptoms are concerned, in those cases of Reiter's syndrome that I have treated with N.A.B. The joint lesions did not appear to be greatly affected, though they all cleared up more quickly than might have been expected, and no new lesions were seen after the completion of the N.A.B. treatment. No relapses have been seen up to the time they were lost sight of (six to nine months). In so variable a disease this observation is not of much value. It should be noted that Reiter found arsenic, in the preparation used by him, ineffective, as also have some other workers. The failure of the joints to respond was not unexpected, and finds a parallel in the effect of arsenic on the genital tract lesions of abacterial pyuria.

I have suggested elsewhere (Baines, 1947) that abacterial pyuria is a coital, if not a venereal, disease. Vassallo (1946) came to the same conclusion. He assumed that the urethritis and cystitis were parts of an ascending infection. I have gone further and suggested that the whole urinary and genital tract may be infected by an organism gaining entrance through the urethra. It seems possible that the other symptoms seen in Reiter's syndrome may be a further extension of the same process. In the investigation into abacterial pyuria mentioned above it was thought that there was a characteristic cystoscopic picture in this condition. Two of the cases reported below underwent cystoscopic

examination in the acute stage and the findings were exactly similar to those seen in abacterial pyuria.

Lever and Crawford (1944) pointed out that the whole triad of Reiter's syndrome is not always present. This may be due to the urethritis or conjunctivitis not being severe enough to attract the patient's attention. Careful questioning will sometimes elicit a positive history that is not obtained by casual inquiry. However, at the present time many cases of large-joint arthritis of febrile non-rheumatic type are being seen in hospital and no cause found for them. So common were these in one military hospital that a special investigation was set on foot, the results of which are to be published elsewhere (G. Hearn and C. Tinker—personal communication). It is possible that some of these really belong to the same group.

I have not had the opportunity of examining large numbers of women, but the condition appears to be unknown in them. Hollander stresses the fact that although large groups of women were living under the same Service conditions as the men, he did not see a single female case. No undoubted case is reported in the literature. Dienes and Smith's (1942) series of women investigated for L organisms contained some with genito-urinary infections of a non-specific type associated with arthritis. This heavy preponderance of men is also seen in abacterial pyuria. This is a matter of some importance. If the view of the coital nature of the infection in both these diseases is upheld the organism should be found in both male and female tracts. It is possible that it is a normal inhabitant or common infector of the female, who is relatively immune to it. Urethritis in the female commonly goes unnoticed. Further investigation of the apparently minor lesions of the female genital and urinary tract would be interesting, though it is unlikely to progress far until a specific organism can be isolated. Women with arthritis should probably have a more detailed search made for associated lesions.

#### Aetiology of Reiter's Syndrome

Reiter himself attributed the condition to *Spirochaeta forans*. This has been a persistent suggestion, but there has never been any further evidence in favour of it.

More recently it has been suggested that it is due to a virus-like organism. This is probably based on Collier's (1938) work. He found a spontaneous transmissible arthritis in *Rattus norvegicus*, and was able to isolate inclusion bodies from them. He was also able to produce a similar disease in rats by injecting fluid from the joints or blood from a case of human acute rheumatism. This work was confirmed by Beeuwkes and Collier (1942), who gave warning that the results should be regarded with caution until similar inclusion bodies could be demonstrated in humans without transmission through rats, since spontaneous virus disease is very common in these animals. Findlay and co-workers (1939) confirmed these results and were able to show that the organisms resembled the virus of pleuropneumonia. Preston (1942) agreed with this, and incidentally pointed out that the reaction was a pyogenic one resembling human pyogenic arthritis rather than rheumatoid arthritis. Abscesses were sometimes found throughout the body of experimental animals, especially at the site of needling for injection purposes. This is of special interest, since one of the objections raised to a virus aetiology for Reiter's syndrome and abacterial pyuria is the fact that they are essentially purulent diseases; whereas virus diseases are not commonly so. Dienes (1940) and Dienes and Smith (1942) isolated pleuropneumonia-like organisms (L organisms) from the cervical, vaginal, and urethral secretions of women, and from the urethra and prostatic secretions of men. Some of these women had

gonorrhoea, non-specific infections, or arthritis, but some appeared to be normal. All the men had symptoms of prostatitis. Beveridge (1943) found L organisms in 10 out of 24 cases of non-specific urethritis. Klieneberger-Nobel (1945) found L organisms in 40% of patients under treatment for venereal diseases, 33% of patients attending with non-venereal gynaecological conditions, and in 14% of normal ante-partum women. Salaman and others (1946) found L organisms in 6% of normal women and 14% of normal men. The incidence was no higher in men with non-specific urethritis, but was 44% in women with non-specific cervicitis, possibly due to the greater difficulty in excluding gonorrhoea in women. If there was associated gonorrhoea (or *Trichomonas* infection) the incidence rose to 34% in men and 60% in women. If both gonorrhoea and *Trichomonas* were present it was 100%.

This fits in very well with the findings of Dienes and Smith (1942) quoted above, and of Coutts (1946). Denfield's (1946) observations in Nigeria may be of some interest in this connexion. He regards Reiter's syndrome as an allergic reaction to repeated attacks of gonorrhoea. It seems more probable that there is some sort of co-mensalism and that the L organisms (if indeed they have anything to do with the disease) grow more freely in the presence of other organisms.

It is perhaps permissible to speculate somewhat at this point. In my paper on abacterial pyuria I came to the conclusion that it was almost certainly acquired by coitus though not necessarily by extramarital infection. This was based on the almost constant history of recent intercourse, both marital and otherwise, in a series of cases occurring in an army stationed abroad. Urethritis was found in almost every case, though it varied from frankly gonococcal, through post-gonococcal and non-specific ones, to a mild mucoid discharge. In some cases there was a shred of evidence that there had ever been any extramarital intercourse, and the urethritis developed after home leave. One was driven to the conclusion that infection might be due to a normal inhabitant of the vagina. These cases were by no means common compared with those that were frankly venereal. This parallels the statistics of affairs found by Salaman (1946) and by Klieneberger-Nobel (1945), with L organisms present in about 10% of normal women and about 60% of those with gonorrhoea. Kristjansen's (1930) case is of some interest in this connexion. His patient developed a non-specific urethritis and arthritis a week after intercourse with a girl known to have a vaginal discharge, which was repeatedly found to be negative for gonorrhoea. Another man subsequently developed urethritis without arthritis following intercourse with her. There is thus a recurrent suggestion that there is some vague connexion with gonorrhoea; but that cases occur without it is not to be doubted. In this the clinical and pathological findings agree. Salaman has made an alternative suggestion that L organisms are stages in the life cycle of the gonococcus.

In view of the suggested mode of infection another organism which must be considered is *Trichomonas vaginalis*. This was strongly pressed as a likely cause of abacterial pyuria by Lydon (1945), but other workers have failed to find it in this condition, nor are the symptoms the usual ones of known *Trichomonas* infection in the male. Incidentally this organism does not usually respond to N.A.B. It is more probable that *Trichomonas*, when present, is a co-infectant. Its relation to L organisms is mentioned above.

One other organism has been mentioned. Coutts (1946) attributes Reiter's syndrome to the virus of lymphogranuloma venereum, and states that he found positive

rei tests in the condition. In the majority of his cases there was an associated gonococcal urethritis. As Coutts (1943) points out, double infections are not uncommon in venereology, and it is possible that yet another organism was acquired at the same time as his two other common infections. He also found a similar condition in women (Coutts, 1944), and in the so-called Behcet's syndrome. Frei tests are not infrequently reported as positive in Reiter's syndrome. This may be due to the fact that it is probably not entirely specific for lymphogranuloma. Some of the viruses of atypical pneumonia, and possibly psittacosis, appear to have antigenic affinity with that of lymphogranuloma (Sargent, 1945).

### Case I

The patient, a male aged 40, five years previously developed non-gonococcal urethritis one month after exposure. This responded to sulphonamides. Shortly afterwards he had a dry pleurisy which lasted only a fortnight. He remained well for two years, until he again developed pleurisy. This cleared in six weeks, but twice relapsed at intervals of a month. Full investigation revealed no cause for this. Shortly afterwards he had a recurrence of his urethritis, and at the same time developed a painful arthritis of his left knee. Tuberculosis was suspected. X-ray examination revealed an area of trans lucency at the upper end of the tibia which was not thought to be responsible, and the nature of which was not known. Lymph-gland biopsy was carried out and showed only "chronic inflammatory change." Guinea-pig inoculation with gland extract was negative. He also had a mild conjunctivitis at this time. Both this and the urethritis cleared up and the knee settled completely in about three months.

He had no further trouble until two weeks before his present admission, when his discharge recurred. Ten days later he developed a bilateral conjunctivitis and arthritis of the left shoulder and ankle and right elbow. Most of the inflammation was periarticular. There was some frequency of micturition and occasional "stammering" but no pain.

**Investigations.**—Urethral discharge and prostatic bead: pus + + + +; no gonococci; Gram-positive cocci; culture of *Staphylococcus albus*. Midstream urine: normal; dark-ground, no spirochaetes. Swab from eye: diphtheroids. Blood count: normal. E.S.R.: 29 mm. in 1 hour. Serum agglutinations for dysentery: negative. X-ray examination of joints revealed nothing abnormal. Cystoscopy: the bladder contained a large amount of pus which, in the absence of any sign of inflammation and a clear efflux from both ureters, must have come from the posterior urethra, which was markedly inflamed.

Once again the condition settled down without specific treatment, and at the end of a month he was nearly normal.

**Comment.**—This appears to be a classical case of Reiter's syndrome following on a non-specific urethritis. There have been three relapses in five years, with complete recovery on each occasion. The association of pleurisy may be of interest. It has not previously been reported as part of the syndrome, and may in fact have nothing to do with it. I have seen one other case in which a severe fibrinous pleurisy with marked x-ray changes was associated with a very acute abacterial pyuria. Further observations are required.

### Case II

A man aged 25, with a healthy history; no dysentery. Six weeks before admission he developed a watery discharge after several extramarital exposures. This was non-gonococcal (smears and culture), and cleared up with sulphonamides. Two weeks later he began to have haematuria, dysuria, and frequency (D/N=30/20). A fortnight before admission he developed bilateral conjunctivitis, and four days later his left ankle became swollen. During the following week the other ankle and both knees were involved.

On admission he had a mild conjunctivitis, and a peri- and intra-articular arthritis of the joints mentioned. Rectal examination showed a tender boggy prostate. Urethral smears were

repeatedly negative for gonococci, but contained a lot of organisms and grew staphylococci and *Ps. pyocyanea* on culture. Urine: pus + + + +; culture sterile. Cystoscopy: fluffy oedematous cystitis with multiple discrete ulcers closely resembling those seen in abacterial pyuria. The gonococcal flocculation test and Wassermann reaction were negative, as was the Frei test. Stools and agglutinations were negative for dysentery. The blood count was normal, and the E.S.R. was 18 mm. in 1 hour.

He was treated with penicillin, 1,000,000 units, and sulphathiazole, 30 g., without effect. He was then given N.A.B., 0.3 g., three doses at four-day intervals. Improvement in the urinary symptoms was rapid, and he was normal by the tenth day. There was a slight flare-up of the joints after the second injection, and at this time the E.S.R. was 30 mm. in 1 hour. From this time improvement was rapid and he was able to get up in a fortnight, being discharged a few days later. Cystoscopy sixteen days after N.A.B. was started showed a dramatic change in the bladder, which was now normal apart from slight congestion of the vessels.

**Comment.**—The urinary picture is that of abacterial pyuria, and is associated with conjunctivitis and arthritis. The joints were responding to rest, but the urinary lesions were untouched till N.A.B. was given, when the expected dramatic response was found. Thereafter the joints rapidly settled. It is not possible to say if the N.A.B. had any effect on the joints since they vary so much spontaneously. The flora of the urethra was not regarded as being of much importance in view of the sterile urine and characteristic cystoscopic findings.

### Case III

Two months previously the patient, a man aged 22, had been treated with penicillin for acute gonorrhoea. The urethritis never cleared and he began to have haematuria, dysuria, and frequency of micturition. He was given a course of sulphathiazole, which stopped his discharge, but this recurred a week before admission. Four days later his shoulder swelled and became painful. Two days after this the left knee was also involved.

On admission he had an irregular temperature of 100°–103° F. (37.8°–39.4° C.). There was a mixed intra- and extra-articular arthritis of the shoulder and knee. The leucocytes numbered 17,000; E.S.R. 30 mm. in 1 hour. Urine: pus + + + +; culture sterile. Repeated urethral smears were negative for gonococci. Mild conjunctivitis appeared on the following day; this lasted for four days, but recurred three weeks later and again disappeared. During the succeeding days various other joints were involved. The pain and swelling flitted from one to the other and recurred.

Cystoscopy showed severe patchy cystitis—parts of the apex and lateral walls being clear—maximal round the ureteric orifices; multiple plum-coloured small ulcers; the general appearance being one of pink fluffiness characteristic of abacterial pyuria. In view of this he was treated with N.A.B. in the usual way. The urinary symptoms cleared up within a week.

The E.S.R. rose to 95 mm. in 1 hour on the eighteenth day and thereafter fell. His joints slowly recovered, and he was able to get up at the end of two months, being discharged a month later.

During the course of his illness he had three attacks of nose-bleeding. It is possible that these were due to involvement of the nasal mucosa, but no ulceration could be seen in the nares.

**Comment.**—This case was actually the first one seen. The patient was examined at a time when abacterial pyuria was being investigated, and it was clear that so far as his urinary lesion was concerned there was no difference from the other cases we were seeing. (The original presence of gonorrhoea we regard as of no importance, since it is a not uncommon co-infectant in cases of abacterial pyuria. The reasons for thinking that this is so are given in full in the paper (Baines, 1947) on this subject.) This is why we started treating these cases with N.A.B. in spite of the

bad reports from the earlier workers. We found that the urinary lesions clear up in Reiter's syndrome, just as they do in abacterial pyuria. It is difficult to assess the effect on the joints, since these are so variable in any case, but we are inclined to think that, at any rate, no further involvement occurs after the use of N.A.B. An adequate opinion cannot be given until much further trial has been made. One wonders whether the joints may not be an allergic reaction to the primary urethral infection. The effect of N.A.B. on the urethral lesion is in any case obscure (in contrast to the effect on the bladder).

#### Case IV

A man aged 43 had been treated with penicillin for "urethritis" six weeks previously. Since the dose given was not the standard dose for gonorrhoea it is probable that a firm diagnosis was not made. The urethritis cleared up but relapsed a few weeks later, and at this time he had a mild conjunctivitis which lasted about a week. Shortly after this he began to have painful and frequent micturition. Within a few days he developed an arthritis of his left knee. During the next ten days various other joints became involved, including the right knee, ankles, big toe, shoulder, elbow, and spine.

On admission he was febrile—100°–101° F. (37.8°–38.3° C.) and in great pain. All the accessible joints had the same appearance, being hot, tender, and with intra- and extra-articular swelling. Urine: pus +++; culture sterile. Repeated urethral smears and prostatic beads were negative for gonorrhoea. The gonococcal flocculation test and Wassermann reaction were negative.

In view of the possibility of gonorrhoea, even in the absence of any positive findings (but after primary penicillin), he was given 1,000,000 units of penicillin and 30 g. of sulphathiazole concurrently. This had not the slightest effect. His urethritis and haematuria got worse. The joints varied from day to day. He then had a course of N.A.B. The urinary lesions cleared up in a few days and did not relapse. The joints continued to vary but improved slowly from this time, and he was able to get up in six weeks. When discharged to light duty a month later there was still some residual stiffness, and a little thickening round the ankles. A skiagram of the big toe showed a destructive arthritis of the metatarso-phalangeal joint; the other joints were normal.

*Comment.*—This case is somewhat similar to the previous one. It is obviously not absolutely possible to rule out gonorrhoea, but we do not regard this as essential. The presence of abacterial lesions responding to N.A.B. makes it pretty certain that even if gonorrhoea was originally present it was a dual infection. It certainly illustrates the difficulties of diagnosis. However, the remarkable recovery of these cases suggests that the condition is not gonorrhoeal in origin.

#### Case V

This patient, a man aged 26, had had a non-gonococcal urethritis and epididymitis three months before admission. Two weeks before admission he had a sore throat, and 12 days later he developed a mixed peri- and intra-articular arthritis of both knees and one ankle. There was a mild irregular fever. The urine was normal, and prostatic bead, W.R., and G.F.T. were all negative. E.S.R., 36 mm. in 1 hour. With rest in bed there was some improvement, but a week later he had an acute flare-up with pyrexia to 101° F. (38.3° C.). The leucocytes numbered 8,900. E.S.R., 80 mm. The joints continued to vary, the arthritis shifting from one to another and also involving the shoulder. The E.S.R. slowly sank. Since resolution seemed to be very slow he was given a course of N.A.B. After this the temperature remained steady, and the E.S.R. fell to 8 mm. Convalescence was uninterrupted.

*Comment.*—This case is probably not one of Reiter's syndrome. It is included to illustrate the difficulty in knowing what should be classed under this heading, and as an illustrative case of a type now common. The arthritic

lesions were typical enough of the variety seen in Reiter's syndrome, and it followed a non-specific urethral infection. Conjunctivitis was not seen, but this is often absent. N.A.B. was given to discover if it could be used in any way as a therapeutic test; but it was impossible to say what effect, if any, it had in this case. Certainly the condition settled rapidly after it had been given, but it was already beginning to do so before treatment was started. Until some specific test is evolved or an organism found, this difficulty will continue. All that one can hope is that in queer cases of arthritis the diagnosis will be considered and adequate investigations be made.

#### Summary

Reiter's syndrome is a convenient diagnosis for cases of arthritis associated with lesions of the mucosal surfaces. Whether it is a single and real entity will not be proved till a causative organism can be identified and Koch's postulates fulfilled.

There is enough evidence to show that it is neither gonococcal nor dysenteric in origin. The reasons for regarding it as being due to a virus are attractive, but at the moment there is little real evidence on this point.

I have tried to show that there is some reason for believing that the primary lesion is probably urethral. The importance of this has not been adequately stressed in the past. There is no apparent difference between the genito-urinary lesions of Reiter's syndrome and those of abacterial pyuria. It has been suggested that the latter is sometimes associated with other lesions of the genital tract, and this may be but another facet of a widely invasive disease.

Treatment is most unsatisfactory. It is exceedingly difficult to assess. The only thing which seems certain is that the urinary lesions when present in the florid state clear up with N.A.B. just as they do in abacterial pyuria. How far this affects the joints is open to doubt, and we must await the passage of time and a careful follow-up of many cases. It has been condemned in the past.

It is perhaps worth calling attention to the not uncommon cases which resemble Reiter's in one or more respects but can hardly be included with certainty. Many of these are associated with non-specific lesions of the genito-urinary tract. Too frequently it has been assumed that these are all gonococcal. This is probably not true, and they should repay a more careful study. Certainly the urethra and prostate must be searched in every doubtful case of arthritis. Greater knowledge will surely follow better investigation.

I am greatly indebted to Prof. A. P. Thompson for permission to use Cases I and II, which were under his care; also to his residents, Drs. Hayward and Fisher, who undertook most of the tests and investigations in these two cases.

# PHOTOSENSITIVITY TO SUNLIGHT FROM USE OF PROPHYLACTIC SULPHONAMIDES

## ITS RELATION TO VACCINATION REACTIONS

BY

GEOFFREY WATKINSON, M.D., M.R.C.P.

*Squadron Leader, R.A.F.; Medical Specialist*

AND

BARCLAY R. HILLIS, M.B., Ch.B.

*Flight Lieutenant, R.A.F.*

On an R.A.F. station during April and May an outbreak of streptococcal tonsillitis occurred, 65 cases being admitted to the isolation block in a period of 61 days. In the same period 7 cases of rheumatic fever developed, apparently as a sequel to a preceding throat infection. In an attempt to control the epidemic it was decided to administer prophylactic sulphanilamide tablets to a body of men exposed to the infection and to compare the incidence of infection in those receiving the drug with the incidence in those untreated.

The drug appeared to control the epidemic, for in the period of prophylactic therapy the cases occurring in comparable numbers of treated and untreated personnel were reduced to one-third in treated cases, and remained at eight-ninths of the previous admissions in those unprotected. The treatment, however, produced a high incidence of toxic effects, shown by transient photosensitivity rashes occurring only in personnel who had recently been vaccinated and coinciding with the development of the pustular stage of the vaccination lesion.

### Clinical Observations

The personnel studied comprised a training wing of a Royal Air Force unit. They received prophylactic sulphanilamide tablets in a dosage of 2 g. daily; in all 470 men were treated. While under training routine vaccination was performed, T.A.B. inoculation being no longer undertaken as a routine. The majority of the men received the tablets for 10 days (total 20 g.), when because of the high incidence of rashes the treatment was suspended. All men under treatment were questioned individually as to their regularity in taking the tablets and were asked if they had previously received sulphonamides orally or locally; they were also examined for rashes and the state of their vaccination lesions was noted. No history of previous sulphonamide therapy was obtained in any of the cases, while a few of the men admitted to taking less than 5 g. of the drug. Two such cases developed rashes at the height of their vaccination reactions.

Environment, diet, the effects of vaccination alone, and other factors which might have contributed to production of the rashes were excluded by a study of a large control body of men on the station subjected to identical living and training conditions in whom no rashes occurred. These controls comprised approximately 2,250 men not receiving prophylactic sulphanilamide and not recently vaccinated, and 1,500 not receiving sulphanilamide but recently vaccinated.

### Rashes Encountered

The development of the rash coincided in all cases with the development of the pustular stage of the vaccination lesion and occurred exclusively in areas exposed to sunlight. The cases, owing to standard Service dress, showed a striking similarity in the areas involved. These consisted

of the head and neck except a small V-shaped area on the forehead shaded by the forage cap; the arms and forearms unprotected by rolled-up sleeves; and, in a few cases, a small band round the ankles where the sunlight had penetrated the gaiters. A few men had sunbathed during the period of administration and had developed more extensive rashes in the areas exposed.

The rash consisted of small dusky-red papules on a dusky erythema, which in severe cases coalesced into a confluent large macular lesion. Severe cases developed a marked conjunctivitis with or without oedema of the eyelids. In four cases areas of small vesicles developed. The rash faded in less than a week, leaving brownish desquamating areas. The rash was intensely pruritic.

Rashes developed in 136 (34.6%) of the 470 personnel treated, a much higher incidence than reported by previous workers. The high proportion of rashes, we submit, is due to the combination of three factors—the sulphanilamide, excessive sunlight, and associated vaccination reactions.

The cases affected have been divided into three grades of severity: by "severe" rash is meant a confluent macular lesion on head, neck, and arms, associated with conjunctivitis, with or without oedema of the eyelids, fever, and constitutional disturbance; by "moderate" is meant a maculo-papular lesion involving the same areas but unassociated with fever and constitutional disturbance; and by "mild" is meant a small localized papular and erythematous lesion without general reaction. Of the 136 rashes 23 were severe, 43 moderate, and 70 mild.

### Relation to Vaccination Reactions

The 470 cases receiving prophylactic sulphanilamide were divided into four groups showing decreasing incidence of rashes; they varied only in the time at which vaccination was performed. All cases received 10 days' sulphanilamide, and were divided as follows:

*Group A.*—In this group 213 men received sulphanilamide from the first to the tenth day after vaccination—i.e., *when the reaction was developing*. An explosive outbreak of 106 (49.3%) rashes occurred on the tenth day, coinciding with the development of the pustular stage of the vaccination lesion. Of these rashes 20 were severe, 35 moderate, and 51 mild. The degree of rash appeared to be directly related to the severity of the vaccination reaction.

*Group B.*—This group consisted of 99 men who were vaccinated after receiving prophylactic tablets for eight days, the tablets being suspended two days later—i.e., *when vaccination reactions developed eight days after the treatment was suspended*. Despite the suspension of the tablets 26 rashes developed (26.3%), again coinciding with the development of the pustular stage of the vaccination lesion. Of these rashes 3 were severe, 8 moderate, and 15 mild.

*Group C.*—This contained 87 men who received prophylactic sulphanilamide from the fifteenth to the twenty-fourth day after vaccination—i.e., *when the vaccination reaction had subsided*. A much lower incidence of rashes was encountered, only four (4.6%) mild rashes developing. In all these cases it was found that the vaccination pustule was still unhealed; no rashes occurred where the lesion had become inactive.

*Group D.*—Ten days' prophylactic sulphanilamide was given to 71 men who had *either refused vaccination or in whom the vaccination had failed*. No rashes occurred in this group—stressing that in the absence of vaccination toxic effects would have been minimal.

These results are summarized in the Table.

### Discussion

Many observations concerning the prophylactic use of sulphonamides in the control of rheumatic fever, meningitis, and streptococcal and other infections are on record, these

Table of Results

Description of Cases	No. of Cases	Vaccinated	Rashes Developing	Incidence	Degree of Rash		
					Severe	Moderate	Mild
Group A	213	Day after starting tablets	106	49.8%	20	35	51
Group B	99	2 days before tablets suspended	26	26.3%	3	—	15
Group C	87	15 days before receiving tablets	4	4.6%	—	—	4
Group D	71	Failed or refused	Nil	Nil	—	—	—
Total ..	470	—	136	34.6%	23	43	70

drugs being effective protective agents and having been administered to large numbers of men with minimal toxic effects. Thus Coburn (1944) in the control of streptococcal infections administered sulphadiazine in doses of 1 g. daily for several weeks to some 250,000 personnel of a naval establishment. Mild evanescent drug rashes occurred in 0.2–0.7% of cases, necessitating suspension of the therapy in 0.3%. The rashes developed after two to three weeks' administration of the drug, when 7–20 g. had been given. Severe drug rashes occurred in 0.005%.

Similar figures are reported by Holbrook (1944), who administered daily 1-g. doses of sulphadiazine to 40,000 troops with only 33 rashes (0.08%). Lee (1944) reviewed reactions following the mass administration of a single 2-g. dose of sulphadiazine to 25,000 men and women, in whom 128 reactions developed, fifteen being classified as mild cutaneous rashes and four as severe cutaneous eruptions. Other workers dealing with the use of prophylactic sulphonamides quote an incidence of skin lesions of 0.03% in 18,000 men who received 4 g. of sulphadiazine in one day (Painton, 1944) and a 0.38% incidence of toxic effects, nature unspecified, in 9,000 men of the A.A.F. who received 3-g. doses of sulphadiazine twice weekly (Warren, 1944). The most recent series, that of Billow and Albin (1946), quotes an incidence of 63 rashes in 20,000 troops receiving daily doses of 1 g. of sulphadiazine (0.32%).

Our incidence of rashes (34.6%), therefore, was very much greater than ever previously reported in the use of prophylactic sulphonamides, the higher incidence, we submit, being due to a coincidence of the drug's administration and vaccination. In a search through the literature we could find no reference to this relationship.

The personnel receiving the therapy were divided into four groups according to their relation to the time of vaccination. The first group developed their vaccination reactions while the drug was being administered and showed the highest incidence of rashes (49.8%). The second group, in whom pustular vaccination lesions developed some eight days after the drug had been suspended, surprisingly developed rashes in a large percentage (26.3%). In this group the latent period between the suspension of the drug and the development of the rash was therefore much longer than previously reported, among others by Erskine (1942) and Park and Platts (1942), who described photosensitization rashes developing 48 hours after the drug had been suspended. In the third group, in whom vaccination reactions had subsided, four (4.6%) rashes occurred only in cases where the vaccination pustule remained unhealed. No rashes were present in a fourth group of 71 men in whom vaccination had failed or had been refused. It would appear, therefore, that a toxin eliminated from the vaccination pustule combined with the sulphonamide had acted as a powerful photosensitizer.

The rashes encountered conformed to descriptions given by other workers. Photosensitivity in sulphonamide therapy

was described first by Goodman and Levy (1937) and Ballenger *et al.* (1937) among others. Park and Platts (1942) recorded 27 cases, and Peterkin (1945), in a review of 500 sulphonamide rashes seen in North Africa and Italy, classified 361 (72.2%) as light-sensitization rashes. He described four types of light-sensitization rash—erythematopapular, vesicular, severe (which showed bullae, crusting, and oedema), and telangiectatic. In his series the severe type was the most common, comprising 61.8% of the total rashes. In the present series all but four cases were of the erythematopapular type, the remainder being vesicular. The presence of conjunctivitis sometimes associated with oedema of the lids was mentioned by Lee (1944) in his description of rashes occurring in his series. These symptoms appeared in all our severe cases. The conjunctivitis combined with a rash suggested rubella in some of our more diffuse cases, this point of differential diagnosis being described also by Billow and Albin (1946). Peterkin (1945) in his discussion on photosensitivity stated that duration of sensitivity may vary between forty-eight hours and two and a half years. He also stated that patch-testing gave erratic results, tending to be positive only in areas affected by the rash. In none of our cases did the rash recur on further exposure to sunlight, and patch-testing, both in areas affected and in those unaffected by the rash, gave uniformly negative results in 30 of the severer cases, stressing that the lesion was a transient photosensitivity rather than a true sulphonamide dermatitis.

Opinions vary whether any one sulphonamide compound is more prone to reactions. Erskine (1942) considered the incidence of toxic effects to be equal in the various compounds employed. In the 27 cases recorded by Park and Platts (1942) 21 were due to sulphanilamide. Peterkin (1945) considered sulphanilamide most likely to cause reactions, and attributed this fact to its wider use as a local application. Sulphanilamide was used in the present series in the interests of economy, and, although the dosage was heavier than that employed by some workers, it in no way exceeded the dosage used by Thomas (1944) in the prophylaxis of recurrences of rheumatic fever over a period of seven years. Aberrations of chemical constitution in the drug which might have contributed to the toxic effects were excluded by analysis kindly performed on tablets of the same batch by Messrs. Boots Pure Drug Co.

Three hypotheses have been advanced concerning the mechanism of sulphonamide photosensitivity. The phenomena of sensitization due to previous oral or local administration have been long recognized, but no history of previous therapy could be elicited in any of our cases. Secondly, Rimington and Hemmings (1938) found that an increased output of porphyrins occurred in sulphanilamide therapy together with coproporphyrin I, which is a photosensitizer. The amount excreted varied considerably in individuals and contributed to their proneness to toxic reactions. Facilities for the estimation of the urinary output of porphyrins were unfortunately not available, and no further observations could be made on this point. Our work would seem to support a third hypothesis put forward by Erskine (1939), who considered that drug reactions are due to the liberation by the drug of toxins from a buried toxic focus. In our series the vaccination pustule may have acted as an inflammatory focus from which toxins were liberated by the sulphonamide, causing photosensitivity.

There would seem, therefore, a considerable risk of light sensitization rashes if sulphonamides are administered, even in small dosage, in the presence of an active vaccination pustule, and their use in recently vaccinated ambulatory personnel is not advocated. Fortunately all the rashes developing were evanescent; but true sulphonamide sensi-

tivity remained a possibility, and subjects with rashes were advised to warn doctors in the future of the possibility of their being sensitized. The mechanism of the phenomena is obscure, the drug, the vaccination lesion, and light all playing a part.

### Summary

In the control of streptococcal infections in an R.A.F. station prophylactic sulphonamides were administered in a dosage of 2 g. daily for ten days to 470 personnel.

A high incidence (34.6%) of photosensitization rashes occurred, due to a combination of three factors—the sun, vaccination, and sulphanilamide.

The highest incidence of rashes was found in men recently vaccinated, and coincided with the development of the pustular stage even when this occurred after the drug had been suspended. No rashes appeared in personnel in whom vaccination had failed or was refused.

The literature relating to toxic reactions occurring in the use of prophylactic sulphonamides and to sulphonamide photosensitivity is discussed.

The evidence produced shows that a combination of sulphanilamide administration to ambulatory personnel and vaccination will cause a high incidence of transient photosensitization rashes.

Our thanks are due to the Director-General Medical Services, Royal Air Force, for allowing us to publish this article; to Air Vice-Marshal Rook, Consultant in Medicine, Royal Air Force, for his comments on the paper; and to Wing Commander S. B. S. Smith, who extended to us facilities for the study of the personnel treated.

## BELLADONNA POISONING

BY

M. HAMILTON, M.B., M.R.C.P.

Flight Lieutenant, R.A.F.V.R., Graded Medical Specialist

AND

A. B. SCLARE, M.B., Ch.B., D.P.M.

Flight Lieutenant, R.A.F.V.R., Neuropsychiatrist

Glaister (1944) states that cases of accidental poisoning by belladonna preparations are comparatively rare. The following case is, we think, unusual enough to merit publication.

### Case Report

A corporal in the Polish Air Force, aged 42, was admitted to a Royal Air Force hospital at 11.20 p.m. on Nov. 4, 1946. He was unable to give a clear account of himself, and the history was obtained from a sick-quarters orderly. The patient reported to the station sick quarters at 4.15 p.m. complaining of vague abdominal discomfort. He was given some medicine, stated to be a gastric mixture. About 7 p.m. others sharing his billet noticed his confused state and took him to the sick quarters, whence he was transferred to hospital. Before admission he was given omnopon, 1/3 gr. (22 mg.), and scopolamine, 1/150 gr. (0.43 mg.).

On admission he was found to be in an extremely restless and agitated condition. While awaiting transfer to a ward he

wandered aimlessly round the reception-room, picking up every object he encountered, including a telephone directory and the curtain, and attempting to eat it. He was unable to appreciate his surroundings, and failed to recognize the friends who accompanied him. His speech, which was thick and confused, consisted of an unintelligible jargon. His gait was reeling and incoördinate. In the ward he strongly resisted attempts to undress him. Resistance was accompanied by vague gestures of physical violence, which soon gave way to an air of fatuous resignation.

On physical examination the face was markedly flushed, the mouth dry, and the tongue coated with a heavy brown fur. The breath was not offensive. The temperature was 98.4° F. (36.9° C.). The pulse rate was 122, and its rhythm and tension were within normal limits. The blood pressure was 150/90. Examination of the heart, chest, and abdomen was negative. On admission the respiratory rate was 20. The bladder was distended, being felt 3 in. (7.5 cm.) above the symphysis pubis. The pupils were circular, equal, and widely dilated, with only a thin surrounding rim of iris. They reacted sluggishly to direct and consensual light. There was no nystagmus, and eye movements were full. The fundi were normal. There was a generalized muscular hypertonus, amounting almost to spasticity. The tendon reflexes were exaggerated. The abdominal reflexes were elicited with difficulty, and the plantar responses were flexor. Some ill-sustained ankle clonus was observed, but no patellar clonus. Sensory examination was unsatisfactory owing to the mental state.

Attempts to pass a gum-elastic catheter failed owing to an obstruction in the region of the membranous urethra. However, some 30 minutes later he passed a large quantity of urine, a specimen of which contained no chemical abnormality. In view of the widely dilated pupils, flushed face, dry mouth and tongue, mental state, tachycardia, and distended bladder, a tentative diagnosis of belladonna poisoning was made. As the patient soon became more rational and co-operative, no active measures were indicated. He slept well, and no further confusional symptoms occurred.

On awaking the following morning he was somewhat bewildered, and was amnesic for the events of the previous evening, the last episode he remembered being the administration of some "black medicine." Physical examination was now entirely negative apart from the pupils, which were still somewhat dilated and reacted sluggishly to light. He was mentally alert. Information was received that the "black medicine" was not, as intended, 10 min. (0.59 ml.) of tincture of belladonna, but 10 min. of the liquid extract of belladonna. On Nov. 6 he was mentally and physically normal, and was returned to his unit. Five months later he was in good health. He stated that 10 to 15 minutes after taking the medicine he noticed difficulty in focusing near objects, presumably due to failure of accommodation. A dose of 1 min. (0.059 ml.) of liquid extract of belladonna by mouth produced no ill-effects, except slight dryness of the mouth occurring after one hour and persisting for about 45 minutes. There was no change in pulse, respiration rate, or size of the pupils. It is therefore concluded that there was no element of idiosyncrasy.

### Discussion

In this case acute symptoms of belladonna poisoning, followed by rapid recovery, resulted from the administration of a dose which was small compared with that in previously recorded cases. The dose was 20 times that intended: 10 minims of the extract being equivalent to 1/15 gr. (4.3 mg.) of alkaloids, while 10 minims of the tincture is equivalent to 1/300 gr. (0.22 mg.) of alkaloids, calculated as hyoscyamine. Clinically the case conformed fairly well to standard descriptions, but the disordered behaviour, the hypertonus, and the transitory urinary retention (due, presumably, to spasm of the external sphincter) were noteworthy.

Most of the cases described in the literature have followed the external applications of belladonna preparations. Moorhead (1919) described two cases following the absorption of belladonna liniment through the unbroken skin after

massage. Métivier (1935), Duggan (1937), and Hopkins and Robyns-Jones (1937) recorded cases due to the instillation of atropine eye solutions. The last mentioned occurred with washing out the eye with 1% atropine solution after an iridectomy operation. Carter (1940) described the case of a man who swallowed 5 drachms (19.4 g.) of the liniment (equivalent to  $1\frac{1}{2}$  gr. (90 mg.) of alkaloid) in mistake for a cough mixture. The onset of symptoms was delayed 10 hours, and complete recovery followed treatment by spinal drainage, morphine, and physostigmine.

Glaister comments on the variations in dosage found to cause symptoms: 2 gr. (0.13 g.) of atropine have proved fatal, while recovery has followed a dose of  $5\frac{1}{2}$  gr. (0.35 g.). Although in our case the amount was ten times the pharmacopoeial dose of the liquid extract (1 min.), the dosages in previously recorded cases have generally been much higher. It appears, therefore, that symptoms of poisoning accompanied by a gross mental disturbance can result from only a moderately excessive dosage.

### Summary

A case of accidental belladonna poisoning is described, presenting as an acute confusional state.

The onset of visual symptoms occurred within half an hour of taking 10 minims of the liquid extract, while the onset of general symptoms was delayed for three hours.

Recovery occurred within twelve hours without active treatment.

Subsequent testing for idiosyncrasy proved negative.

We wish to thank Group Captain C. G. J. Nicolls for permission to publish this paper and Prof. J. Glaister for his helpful advice.

## SUPPRESSION OF SYPHILIS AND PRECOCIOUS TERTIARISM

BY

JAMES MARSHALL, M.D.

Director, Venereal Diseases Clinic, Royal Northern Hospital,  
London

In cases of early syphilis treated with penicillin in standard doses (2,400,000 units or more) relapse or failure of treatment may be manifested in the following ways (Marshall, 1945): (a) Surface relapse. The relapse lesions may be "primary" or "secondary" in type and have occurred, in patients treated personally, between 59 and 200 days after treatment (average 83 days). (b) Serological relapse, which may occur with or without signs of surface relapse. (c) Sero-resistance. (d) Less common types of treatment failure include neuro-recurrence, ocular and osseous relapse, and persistence of *Treponema pallidum* in surface lesions in spite of treatment.

Precocious tertiarism has not, until now, occurred as a manifestation of relapse in any of the patients I have treated with penicillin alone. This phenomenon has usually been seen in the past in patients who had been inadequately treated for syphilis by a few injections of a trivalent arsenical unsupported by bismuth. It is presumed that the rapid destruction of the spirochaetes by arsenicals deprives the body of its one primordial and essential stimulus to fight

the infection on its own account—namely, the presence over a long period of the pathogenic agent (Stokes *et al.*, 1944).

There is good presumptive evidence that the administration of an inadequate dosage of penicillin in the following case of early syphilis has upset the normal response of the body tissues to infection with *T. pallidum*.

### Case Report

A man aged 30 was first seen in June, 1947, and attended for examination because his wife had been found, at routine antenatal test, to have latent syphilis. (He had been married for one year, and, as a pre-marital serum test for syphilis is obligatory for women marrying serving American soldiers, it can be presumed that his wife was then healthy.) He had not previously shown any manifestations of any venereal disease and gave the following history.

In November, 1945, while on active service in Italy with the U.S. Army, he developed a very itchy rash on the sides of the neck, anterior borders of axillae, trunk, and genitals. The limbs, apart from the upper thighs, were unaffected. The rash did not begin on the genitals and he could not recall any genital ulceration before this time. His last exposure to infection was, he thinks, some six to nine months previously. A diagnosis of scabies was made and he was treated intensively with benzyl benzoate on several occasions over three weeks without relief. At the end of this time he was given 15 or 16 injections of penicillin over two or three days. Individual doses were of 40,000 units, presumably in aqueous solution. The effect was the disappearance of the rash and of the itching in a few days.

It was a routine procedure in his unit for all men to have a serum test for syphilis every six months. He had had tests with negative results in July, 1945 (before the rash), and again a month or two after penicillin treatment.

From November, 1945, he remained in apparently good health, without any skin lesions, until about five weeks before he first attended my clinic. He then developed a rash on his forehead. A few days afterwards a similar rash appeared on his chin, followed a little later by lesions on the penis. Two weeks after the first signs there appeared a spreading lesion of a different type on his left thigh. In the earliest days he had had a sore throat. He had had a serum test for syphilis at a U.S. Army dispensary about a week before he attended, and this was reported as positive.

On examination there were surface lesions of the face, penis, left thigh, and buccal mucosa. The facial lesions consisted of a band of dusky erythema, an inch (2.5 cm.) wide, extending all along the hair margin of the forehead, sealing at the edges and closely studded with pinhead pustules; there was a similar circular patch, one inch in diameter, on the centre of the chin. The mouth showed superficial ulceration of the mucous membrane of the left tonsil and of both commissures of the cheeks. On the shaft of the penis were numerous small purplish oval or circular papules, some eroded, of the type commonly associated with relapsing early syphilis.

On the anterior surface of the middle of the left thigh was a lesion of a different type. This was a roughly circular brown sealing patch, about two inches (5 cm.) in diameter, with a serpiginous edge. The edge showed signs of active spread and had scattered reddish-brown or bluish nodules with superficial scaling. The whole lesion was, clinically, a typical superficial nodular cutaneous gumma. There was moderate enlargement of the lymph glands of the posterior triangle of the neck, of the epitrochlear glands, and of the inguinal glands on both sides.

Dark-ground examination of serum from a penile lesion showed no *T. pallidum*, but in view of the positive serum test, confirmed locally, treatment was not delayed. It was not possible to arrange for lumbar puncture before beginning treatment.

The treatment given on the first day consisted of 0.09 g. "neohalarsine" and 0.2 g. bismuth oxychloride. Three days later the pustular lesions of the face had disappeared, leaving areas of erythema dotted with brownish pigmented spots. The penile lesions had disappeared and the lesion of the thigh was

apparently unaltered. Penicillin treatment was purposely delayed so that non-specific effects could be excluded. Ten days after beginning treatment, penicillin in oil-wax suspension having been superimposed on the arsenic-bismuth therapy, only scattered pigmentation remained on the face and the gummatous lesion was obviously healing rapidly.

### Conclusions

It seems probable that in November, 1945, this man had secondary syphilis, possibly masked by scabies, and that the small amount of penicillin (about 600,000 units) given at that time was sufficient temporarily to suppress the disease. The relapse lesions, appearing 18 months later, were of a secundo-tertiary type.

This case suggests that penicillin in inadequate dosage over a short period can, like the arsphenamines, produce the phenomenon of precocious tertiarism. It illustrates the importance of making an accurate diagnosis in any dermatological condition before using penicillin by injection.

## NICOTINAMIDE AND BLOOD SUGAR

BY

J. N. CUMINGS, M.D.

Clinical Pathologist, National Hospital, Queen Square, London

The effect of nicotinamide (N.A.A.) on blood-sugar levels in normal controls and in diabetic patients has been discussed by Neuwahl (1943), Gordon (1946), and Wade (1947). In view of the different results obtained it would appear worth while to record the following observations, which were made at a time when investigations regarding co-enzyme were taking place.

Three fasting normal subjects were given 0.5 g. of N.A.A. by mouth, and all experienced slight effects such as flushing of the face. Blood-sugar estimations were made by Folin and Wu's method, and co-enzyme was estimated by that of Hoagland *et al.* (1942). The results obtained were all identical in type, and the following table shows one curve that was obtained.

Time	Blood Sugar	Blood Co-enzyme
Fasting	0.105 g. %	4.3 mg./100 ml.
1 hr. after 0.5 g. N.A.A.	0.093 "	4.0 "
1 1/2 hrs. "	0.098 "	4.3 "
2 hrs. "	0.103 "	4.0 "
2 1/2 hrs. "	0.089 "	4.4 "

Two other normal subjects were each given 0.5 g. of nicotinamide and nicotinic acid, and neither showed any variations in blood co-enzyme up to six hours. Another normal subject showed no variation in blood co-enzyme content during the two hours of a blood-sugar curve following 50 g. of glucose by mouth. The blood sugar ranged from a fasting level of 0.099 g. % to a maximum height of 0.186 g. %.

Neuwahl showed two types of response to nicotinamide in normal subjects. One figure demonstrated a marked fall in blood sugar after 0.4 g. N.A.A. intramuscularly and also after 0.25 g. intravenously, whereas in another figure there was a considerable rise in blood sugar after 0.45 g. intravenously. He also showed that 0.06 g. N.A.A. and 2 units of insulin produced a greater fall in blood sugar than did 2 units of insulin alone. Burke and McIntyre (1939), however, had demonstrated earlier that the effect of insulin given to rabbits is not so great—i.e., the blood

sugar is depressed less—in those receiving nicotinamide acid.

Wade has recently shown that nicotinamide produced no alteration in the blood-sugar curves of diabetics following 50 g. glucose, even though his patients had received 1.8 g. of nicotinamide daily for 14 days prior to the second blood-sugar curve.

From these results it would appear that, in general, nicotinamide is without effect on the blood-sugar levels in normal subjects or in diabetic patients. The absence of any effect on the blood co-enzyme content is possibly a further proof of this fact.

This work was undertaken while holding an expenses grant from the National Hospital Research Fund, for which my thanks are due.

## Medical Memoranda

### Transient Hemiplegia following Injection of Sodium Morrhuate

The following case seems to be sufficiently unusual and disturbing to merit publication.

#### CASE REPORT

A married woman aged 32 complained of a small area of varicose vein situated between the knee and the ankle of her right leg. This was not causing any inconvenience, but the appearance was aesthetically objectionable. The injection of 0.25 ml. of sodium morrhuate 5% into the vein as initial treatment caused no general disturbance. One week later 0.75 ml. of the same solution was injected. On this occasion the patient complained of giddiness after approximately two minutes. She then fainted; but she recovered rapidly, and the incident was considered to be due to excitement common to any injection.

The following week 0.75 ml. of the solution was injected into the section of the vein which remained unsclored. Once more nothing occurred for two or three minutes, when the patient fainted again. On this occasion, however, she did not recover consciousness as before, but sank into a state of deep coma. This rapidly merged into a generalized tonic spasm plus slight clonus of the facial muscles. At this stage the patient was pulseless and cyanosed. The tonic spasm persisted for about five minutes and then gradually changed into a state of semicoma. Vomiting now became severe and persistent, but the pulse was more satisfactory. The more anxious moments of the incident appeared to be passing.

The state of semicoma, however, persisted, and further improvement was barely appreciable for about half an hour. At that time it was observed that a complete hemiplegia had developed, involving the right arm, the right leg, and the left side of the face. The patient was then removed to hospital, still in a state of semicoma.

Two hours later the paralysis of the arm and leg had passed off, a limited degree of paresis of the left face still remaining. The patient was able to speak, but articulation was indistinct. In a further four hours the hemiplegia had completely cleared, tendon and surface reflexes were normal, and all movements were complete. Her speech had recovered and the mental state was excellent. Twenty-four hours after admission to hospital she was discharged, recovery being complete.

#### COMMENT

Alarming incidents following the use of sodium morrhuate have been reported occasionally in the medical press, but it is doubtful if the dangers of unusual sensibility to this common preparation are fully appreciated. A case of transient hemiplegia following its use must be exceedingly rare. The satisfactory outcome could not have been foreseen during the severe phase of the coma, and the clinical findings at that stage suggest that recovery was fortunate rather than inevitable. It would appear that the pharmacognosics of sodium morrhuate should be reassessed before its continued use as a sclerosing agent in the treatment of varicose veins be recommended.

W. S. GARDNER, M.B., Ch.B., F.R.F.P.S.

## Reviews

### THE NEW BIOCHEMISTRY

*Dynamic Aspects of Biochemistry.* By Ernest Baldwin, B.A., Ph.D. (Pp. 457. 21s.) Cambridge: At the University Press. 1947.

This is an excellent book and it is to be hoped that its publication will substantially foster the development of the new attitude to biochemistry which is now making itself apparent in many different ways. Traditionally the author of a textbook of biochemistry (or of so-called physiological chemistry or chemical physiology) devotes a large part of its space to an account of the chemistry of the ingredients of living matter, giving proportionately little attention to discussion of the mechanisms involved in building up and maintaining the activity of the living system and to the all-important biological catalysts involved therein—the enzymes. It is true that until the last ten to fifteen years there was little other than conjecture that could be included in the latter category, but within the past two decades much information has become available on the nature of enzyme systems, their mechanism of action, and, most important, their modes of interaction. With this fundamentally new matter to be digested it was clear that a book would have to be written in which all the traditional ideas of the textbook treatment of the subject were abandoned and the whole story was built around the fundamental unit of biochemical function—the enzyme system.

The writing of such a book Dr. Baldwin has achieved in a masterly fashion; his treatment of a complex subject is excellent and the book is extremely readable. In a book with such a new attitude much of the background information on the chemical nature of the *Bausteine* of living systems has perforce been omitted, and the beginner should use this volume to supplement a textbook of the type usual at present. It cannot be emphasized too strongly, however, that Dr. Baldwin's book provides a survey of the dynamic core of biochemistry such as is to be found nowhere else, and it will be of the greatest importance to all those interested in the subject. The diagrammatic representations of many of the cyclic processes in biological systems are particularly clear. The exposition is not limited to man and the higher animals, but includes much important and relevant information about biochemical mechanisms in bacteria and other lower forms of life.

According to Dr. Baldwin's preface elementary biochemistry is taught at Cambridge in two courses. The first and older of these, chemical physiology, forms part of the course in mammalian physiology and caters primarily for the needs of medical and veterinary students. For these, according to Dr. Baldwin, there already exists a wealth of textbooks, which he neither hopes nor desires to supplant by the present volume. While agreeing that his volume should not supplant the older books, particularly for medical students, the reviewer is convinced that the newly developing dynamic spirit of biochemistry will ultimately but inevitably fashion all the textbooks of the future, so that the distinction between them and the later editions of Dr. Baldwin's book will become much less formidable. The present growing understanding of the biochemistry of the normal naturally leads to the elucidation of the biochemical basis of deranged function, and the logical development of therapeutic measures thus becomes possible. For the medical man Dr. Baldwin's book provides a masterly and unique treatment of this most important and rapidly developing background of medical art and science; this is a book he may read with profit and with pleasure.

F. G. YOUNG.

### RECENT SURGERY

*The 1946 Year Book of General Surgery.* Edited by Evarts A. Graham, M.D. (Pp. 679; illustrated. 21s.) Chicago: The Year Book Publishers, Inc. London: H. K. Lewis and Co.

The 1946 issue of this well-known book is, like the previous volumes, edited by Evarts Graham, and we have nothing but praise for his choice of material for inclusion. The cover sheet contains the customary "Quiz": we must confess to being quite unable to answer the majority of the questions without referring to the contents of the book.

It is difficult to appraise adequately a book which is itself a digest of the year's surgical literature. Its emphasis is naturally upon American writings. Among the hundreds of articles summarized we were particularly interested in those concerned with the successful use of vitallium tubes for establishing portocaval anastomoses, new methods of dealing with troublesome verrucae pedis, the creation of an artificial ductus arteriosus in pulmonary stenosis, and the intraperitoneal use of skin grafts to reinforce intestinal anastomoses. There is a disproportionately large number of articles on the treatment of pilonidal sinuses, which suggests that a reliable method of curing this refractory condition has yet to be discovered. The illustrations, usually reduced from the original, are nevertheless clear and helpful.

NORMAN C. LAKE.

### TEXTBOOK OF NEURO-ANATOMY

*The Anatomy of the Nervous System.* By Stephen Walter Ranson, M.D., Ph.D. 8th ed. Revised by Sam Lillard Clark, M.D., Ph.D. (Pp. 532. 417 illustrations, 14 in colour. 32s. 6d.) Philadelphia and London: W. B. Saunders Company. 1947.

This useful and well-known textbook continues to be popular. The Professor of Anatomy in the Vanderbilt University School of Medicine at Nashville has prepared this edition. The most substantial change from the previous one, and a great improvement, is the rearrangement of the text. Dr. Clark has collected the descriptions of gross anatomy into a single chapter near the beginning of the book, and brought forward the chapter on the meninges and blood vessels so that it lies next in sequence. There is some lack of balance here, for the accounts of arterial distribution within the brain are so brief as to appear almost perfunctory in comparison with some other parts of the book.

The removal of "clinical illustrations" from an inconspicuous position in a chapter formerly entitled "A Laboratory Outline" to a special chapter emphasizes their value in the presentation of neurological anatomy. In a future edition we should like to see a more detailed account of the spinal reflexes and the related structural pattern, discussed in a manner similar to that used for the brain-stem reflexes, and also a fuller and more up-to-date discussion of neurobiotaxis.

Prof. Clark has included the results of some new work, but we notice some important omissions—for example, the work of J. Z. Young on peripheral nerves. There is no reference to recent work on the nervus terminalis or to Boyd's work on the innervation of the carotid sinus. The author represents the arachnoid mater as enclosing both buccal and neural portions of the hypophysis, without referring to Wislocki's views. We also looked in vain for reference to recent work on the vascular relations of the neural hypophysis and the hypothalamus. On the other hand there is a relatively full account of the nuclei of the thalamus and hypothalamus, incorporating recent work by Ingram and Le Gros Clark. The book is attractively printed, and it should retain its reputation as an elementary work of reference and a textbook for students of neuro-anatomy.

A. B. APPLETON.

### BROWN-SÉQUARD

*Charles-Édouard Brown-Séquard. A Nineteenth Century Neurologist and Endocrinologist.* By J. M. D. Olmsted, M.A., Ph.D., D.Sc. (Pp. 253. \$3.00 or 16s.) Baltimore: Johns Hopkins Press. London: Geoffrey Cumberlege (Oxford University Press). 1946.

The author can congratulate himself upon his inspiration, for the personality of Brown-Séquard holds special attractions for a biographer. It is surprising indeed that no other medical historian, except the Mauritian Rouget, has attempted to record the vicissitudes and peregrinations of this 19th century neuro-physiologist. The background is unusual. Born a British subject, of a French mother and an American father, in the isle of Mauritius, with Irish blood somewhere in the offing, Brown-Séquard spent his days in restless unsettlement, surrying between the Indian Ocean, Paris, North America, Dublin, and London. He is reported to have crossed the Atlantic sixty times. In the U.S.A. he held chairs in Richmond, Philadelphia, New York, and Boston. During his sojourn in London he acquired a fashionable practice in Wimpole Street, but holds a more lasting claim upon our respect for his founding, with Dr. Jabez S. Ramskill, the National Hospital for the Paralyzed and

Epileptic in Queen Square. This was in 1859. Three years later this pioneering couple of neurologists had taken on three junior colleagues—Sir William Ferguson, J. Z. Laurence, and J. Hughlings Jackson. But Brown-Séquard was off again by 1863. Possessed of a demon which drove him to work at physiological experimentation, at a great pace and at high pressure, he abandoned clinical practice. His earlier researches were concerned with the sensorial effects of partial section of the spinal cord, and they form an important chapter in the physiology of the nervous system. Later investigations, though ingenious and stimulating, were less successful, for he possessed grave defects as a detached observer; only too often were speculation and enthusiasm to lead him astray. It seems probable that an important cause of his being a rolling stone was that he was repeatedly forestalled in his career by his senior colleague Claude Bernard. North American colleges and universities were to him an inadequate substitute for a professorial appointment in his beloved Paris, and it was not until the age of 61, on the death of his rival, that he was appointed to the Chair of Medicine at the Collège de France. His three marriages—and he outlived all three wives—his cult of rejuvenation with testicular autografts, his pursuit of lost causes in physiology, are aspects of a vivid picture of a striking neurologist—brilliant but a little mad.

Such is an outline of the material which Prof. J. M. D. Olmsted, the author of this short biography, has had at his disposal. The product is a delightful trio of addresses, the Noguchi lectures of Johns Hopkins University. They form a scholarly and stimulating contribution to 19th century medical history.

MACDONALD CRITCHLEY.

## OBSTETRICS AND GYNAECOLOGY

*The 1946 Year Book of Obstetrics and Gynaecology.* Edited by J. P. Greenhill, B.S., M.D., F.A.C.S. (Pp. 655; illustrated. \$3.75 or 21s.) Chicago: The Year Book Publishers. London: H. K. Lewis and Co. 1947.

This book will be welcomed in academic obstetrical and gynaecological circles. The volume, compact and handy, contains an accurate review of the previous year's publications, original work receiving due emphasis, with an excellent index of subject matter and authors' names. The abstracts are well chosen, and sufficient attention has been paid to the papers published in Great Britain. Among others the studies of Theobald, Dick Read, Stanley Way, McAfee, Browne and his co-workers, Vatan, and R. C. Thomas are adequately considered. The paper of Edward Davis and Greedy might have been presented more fully, for their study of maternal mortality at the Chicago Lying-in Hospital is one of the most instructive publications of recent years. Gunnar Teilmann's valuable papers are perhaps not sufficiently emphasized, and the abstract is not very clear. It must be admitted, however, that the original papers are not easy to understand. We should mention particularly the work of Varangot and his co-workers on the use of sparteine sulphate and that of Edward Davis and Edith Potter on intrauterine respiration, as well as papers on the transmission of penicillin to the foetus *in utero*, and on the excretion of penicillin in human milk. There is the usual annual review of the treatment of trichomonad infections and of dysfunctional uterine bleeding.

Greenhill's comments have matured with time and are admirable in the present volume. His plea for conservatism in midwifery is sustained and his observations on Miller's extraordinary paper are well worth reading. Editorial comments demand shrewd judgment and they do not always withstand the passage of time. One remembers McClintock's comments in his edition of Smellie. This book is worthy of its predecessors, and indeed in many ways is an improvement on them.

WILFRED SHAW.

*Pye's Surgical Handicraft* has reached its 15th edition and is again edited by Mr. Hamilton Bailey. There are nearly 800 illustrations and in every section an attempt has been made "to present technical procedures pictorially." A few of the illustrations are in colour and the colour is not very good. Apart from this the production is excellent and Mr. Bailey and his team of contributors will obviously be called upon to prepare a 16th edition within the next two or three years. The publishers are John Wright and Sons, Ltd., and the price is 25s.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Loose-Leaf Specialties in Medical Practice.* Renewal Pages Edited by Edgar Van Nuys Allen, M.D. Vols. I and II. New York and Edinburgh: Thomas Nelson. 1947.

Includes new material on antihistamine compounds, antibiotics, the vitamins, and carcinoma of the prostate.

*Bone Dysraphies.* By F. Y. Khoo. (Pp. 169. No price.) Chengtu, China: The Canadian Mission Press. 1945.

A review of bone dysraphies, with extensive references to the literature.

*Chiropractic: Theory and Practice.* By Franklin Charlesworth, F.Ch.S. 3rd. ed. (Pp. 406. £2 2s.) London: Charlesworth and Wiles. 1947.

A textbook of chiropractic, with an introductory account of anatomy and physiology, and many illustrations.

*Modern Development of Chemotherapy.* By E. Havinga, H. W. Julius, H. Veldstra, and K. C. Winkler. (Pp. 175. 15s.) London: Cleaver-Hume Press, Ltd. 1946.

Research into the sulphonamides carried out in Holland during and since the war.

*Contribution à la Connaissance de l'Avitaminose C chez l'Homme.* By J. V. Espin. (Pp. 46. No price.) Paris: Librairie Maloine. 1946.

A monograph on vitamin C deficiency in man, with case histories.

*Tratado Práctico de Hemoterapia.* By Dr. E. S. Sammartino et al. (Pp. 831. No price.) Buenos Aires: Vazquez. 1947.

Discusses blood transfusion, the sources and storage of blood, blood groups, and transfusion reactions.

*Tuberkulöse Reinfektion beim Rinde und ihr Einfluss auf die Resistenz.* By E. Gräub, P.D. (Pp. 93. 12 Swiss francs.) New York and Basle: S. Karger. 1947.

A monograph on tuberculosis in cattle, with an appendix on tubercle bacilli in milk.

*Psychologie du Suicide.* By Gabriel Deshaies. (Pp. 375. 360 francs.) Paris: Presses Universitaires de France. 1947.

The hereditary, social, and psychological factors determining suicide are discussed, as well as methods adopted and the "death instinct."

*On the Problem of Poliomyelitis.* By Bertel S. Son Bertenius. (Pp. 212. No price.) Lund, Sweden: Carl Bloms Boktryckeri. 1947.

A monograph on the incidence and characteristics of outbreaks of acute anterior poliomyelitis.

*Estudio de las Contralateralizaciones, Especialmente Precoces, en los Procesos Pulmonares Tuberculosos de Apariencia Radiológica Unilateral.* By Dr. F. Tello-Valdivieso. (Pp. 77. No price.) Madrid: Publicaciones del Patronato Nacional Antituberculoso. 1946.

An account of tuberculous lesions occurring in both lungs in cases where x rays reveal them on only one side

*La Tuberculosis Pulmonar Inadvertida y los Reconocimientos Radiológicos Seriados.* By Dr. Jose Zapatéro. (Pp. 119. No price.) Madrid: Publicaciones del Patronato Nacional Antituberculoso. 1946.

A monograph on unsuspected tuberculosis discovered by mass radiography.

*The Essex County Health Handbook.* By William A. Builough, M.B., M.Sc., D.P.H. (Pp. 72. No price.) Cheltenham and London: Ed. J. Burrow and Co., Ltd. 1947.

An illustrated pamphlet intended to inform the lay public about the health facilities provided by the Essex County Council.

*Recent Advances in Medicine.* By G. E. Beaumont, M.A., D.M.(Oxon.), F.R.C.P., D.P.H., and E. C. Dodds, M.V.O., D.Sc., Ph.D., M.D., F.R.C.P., F.R.I.C., F.R.S.Ed., F.R.S. 12th ed. (Pp. 422. 21s.) London: J. and A. Churchill. 1947.

Includes new material on synthetic antimalarial drugs, antibiotics, vitamins, thiouracil, primary atypical pneumonia, homologous serum jaundice, and thiocyanates for high blood pressure.

## GENETICS AND SCIENCE IN THE U.S.S.R.

After the Russian revolution the philosophy of dialectical materialism, as elaborated by Marx and his followers, became official in Russia. In theory this might have been expected to affect the development of the natural sciences. In practice, at least for some time, nothing of the kind seemed to happen. The collection of factual information, and its interpretation still seemed to be independent of the religious or philosophical views of the investigator; a Catholic, a Protestant, an agnostic, or a Communist confronted with the same problem still approached it in the same way, within the limits of human error obtained the same results, and then proceeded to draw the same conclusions. Doubtless this was because all these people, in their scientific work, tacitly accepted some form of realist or materialist philosophy. The present generation does not perhaps recall sufficiently often that this attitude of detachment is, in its modern phase, of comparatively recent growth; it is, after all, not very long since the controversies on the theory of evolution. The emergence of a new and militant religion, for it is no less, might well be expected to disturb the philosophic calm, and it would perhaps naturally be expected that the first effect would be seen in the biological field, in the consideration of the evolution and development of the living organism and of its relation to its environment.

It was in biology, and especially in genetics, that the new attitude first seems to have become apparent. The non-Russian scientific world during the last twelve or fifteen years has been startled and confused by the echoes of controversy within the U.S.S.R., a controversy conducted with a vigour that has apparently culminated on occasion in violence. The secrecy that surrounds many Russian activities, the language obstacle, the difficulty of obtaining Russian publications, their unfamiliar form, ignorance of the background, attempts to interpret the Russian writings on Western lines, have all been responsible for much bewilderment. A useful service has, therefore, been performed by the Imperial Bureau of Plant Breeding and Genetics, which has published *The New Genetics of the Soviet Union*, a thorough and fully documented account,<sup>1</sup> by Dr. P. S. Hudson and Mr. R. H. Richens, of the Russian controversy. The authors, in tracing the history of this new development, in expounding the views of the opposing schools, and in bringing forward certain tentative objections to what appears to be the dominant view, have made every effort to be clear, temperate, and impartial. The result is

a masterly and remarkably concise monograph which every biologist should read—and not only every biologist, for it will help all those who wish to understand modern Russian thought in relation to biology and so to medicine.

The leader of the new Soviet genetics is the botanist Lysenko, his principal lieutenant being Prezent. Following some earlier work of distinction, Lysenko (with Prezent) published in 1935 a book which challenged many of the generally accepted fundamentals of genetics as held outside, and also largely inside, the Soviet Union. The attack has gathered force through the years, and there have been bitter arguments at successive genetic conferences. The chromosomes and the genes have been thrown overboard altogether as of no more than trivial significance; it is held that the "pure line" does not exist; that self-fertilization necessarily leads to deterioration; that the cross-bred individual possesses all the potentialities of both parents (i.e., that cross-breeding is an additive process); while any segregation in the F<sub>2</sub> generation is simply a loss by subtraction. The distinction between phenotype and genotype is denied. Inherited characters can be transmitted via the sap from stock to scion in grafts. Lysenko has elaborated a theory of nutrients (this word being used in a very wide sense), organic structures being regarded as having arisen by the conversion of individual "elements" of the environment into the living substance of the plant, which is credited with the capacity for selecting those elements which will confer advantage on the progeny. As a special case of this theory it is supposed that, when offered the choice of mixed pollen grains, the ovum of the plant tends to select one which will confer selective advantage upon the progeny, and certain experimental results have been adduced in support.

The organism, for Lysenko, does not endure as an immutable entity. It is regarded as a stream of stages, each but a momentary reality and engendering from its assimilative union with the environmental nutrients the following stage. The whole flux of stages is the concrete reality, not a hypothetical static entity, the genotype. Moreover, the flux proceeds cyclically, each cycle representing one generation, the similarity between consecutive cycles depending on the assimilation of appropriate nutrients.

The fact that parents tend to produce offspring like themselves is attributed to a principle of "conservatism," which may, however, be "shattered" by adverse environmental conditions, hybridization, or grafting. The authors of the monograph, advancing temperate criticisms of these and other views, repeatedly point out that the theories are often elastic—i.e., that appeal to unknown factors is used to explain away any apparent discrepancy. Thus it is held that earliness—i.e., maturity early in the season—is biologically valuable, and as it is also held that in a cross the potentialities of both parents are fully present, and that the most valuable will be "dominant" and expressed, it follows that the F<sub>1</sub> plant cannot be later than the earlier parent. Further, as segregation on inter-crossing the F<sub>1</sub> plants is held to be due to a subtractive process, it also follows that no F<sub>2</sub> plant can be later or earlier than the parental type. Confronted with exceptions to these rules, Lysenko and his school explain that they would have held only that some (unspecified) biological conditions were wanting.

<sup>1</sup> School of Agriculture, Cambridge, England. May, 1946. Price 6s.

The biologist of traditional outlook confronted with such revolutionary ideas would first want to review the evidence, attempt to repeat the experiments, and to devise critical tests which might be expected to decide between alternative explanations. He would be somewhat deterred by the slightness of the evidence at some points, this being complicated by the fact that the Lysenko school forbids the use of statistical methods; by the elastic nature of some of the theories to which reference has already been made; and by the failure to take into account the immense advances in knowledge in genetics and cytology of the past thirty years—for it is the genetics of 1910 that is under attack. Nevertheless, he would probably feel that certain points brought forward and certain experimental results were worth further investigation. For example, there is the possibility that, after all, mutation may not be a process devoid of direction, a possibility also raised by recent work outside Russia. But simply to adopt such an attitude would be naïve, and the authors of the monograph cannot be acquitted on this score. They conclude:

An attempt has been made to present all the evidence as it appears in the published writings of Lysenko and his school, and to analyse both the merits and defects of his arguments. It is earnestly hoped that by so doing much misunderstanding will have been removed and geneticists of each school will be encouraged to examine their own and each others' data in an unprejudiced light. This should lead ultimately to a synthesis of what is best in both schools, thereby achieving that comprehensive understanding of genetical questions which is the aim of both bodies of investigators.

But is not this to ignore the difficulty of finding a common ground? As the authors themselves make clear, much of the argument of the Lysenko school lies outside the field of accepted Western scientific thought, being alogical—not, that is, illogical, but deriving from beliefs not shared by those who do not accept dialectical materialism. There is the appeal to authority, to Marx, to Darwin, and to the other writers of the accepted books. There is the analysis of the presumed motives and state of mind of opponents and reference to their material circumstances. It is held to be a strong point against hitherto accepted genetics that Mendel was a monk, and Mendelism is charged with being the attempt of clerical reactionary elements to replace the materialistic biological system of Darwin by a veiled form of idealism. Lysenko accuses his principal Russian opponent of to-day of writing as he does through anger at the contempt shown to genetics by the Lysenko school, and through indignation that people of humble origin should presume to criticize the dicta of a closed society of self-regarding geneticists. In condemning Vavilov's Law of Homologous Variation and his theory of Centres of Origin, Prezent in 1939 pointed out that Vavilov was a disciple of Bateson, the notorious anti-Darwinian heresiarch. Timiojavez (an accepted authority) was said to have dubbed Bateson an "irresponsible ignoramus, an unbridled scholastic realist, and a cleric of science." Hence Vavilov's theories too must stand condemned. Accusations of fraud seem not infrequent. The Lysenko school has many opponents, but of course they too preface their arguments by statements of faith in dialectical materialism and are concerned to show that Mendelism

and formal genetics when properly interpreted are not inconsistent with that philosophy nor with the accepted writings. Argument on factual grounds comes second. Whether the biologists of other countries can usefully plunge into these spirited exchanges, and whether they will be thanked if they do, seems doubtful. It would no doubt be useful to send observers, though perhaps these should be philosophers and professors of comparative religion rather than men of science in the Western sense.

It remains to add that the teachings of the Lysenko school are not yet part of the canon of the faith; and, of course, may never be. Official encouragement, however, has not been lacking. At the genetical congress of 1939 the Commissar of Agriculture is reported to have said that "the People's Commissariat of Agriculture of the U.S.S.R. supports Lysenko in his practical work and in his theoretical views and recommends the breeding-stations to apply his methods in seed production and breeding work." Lysenko became President of the Lenin Academy of Agricultural Sciences in 1938, replaced Vavilov about 1940 as Director of the Institute of Genetics of the Academy of Sciences, and has twice been awarded the First Stalin Prize and also the Order of Lenin. He is Vice-Chairman of the Supreme Soviet. Some at least of his opponents, however, have not ceased to criticize his views, though apparently avoiding controversial issues to a certain extent. Zhebrak has published letters in the foreign scientific press stressing this opposition and stating that a belief in many at least of Lysenko's theories is not obligatory. But Zhebrak, according to the *Manchester Guardian*,<sup>2</sup> is now being subjected to a heresy hunt. Three Communist poets have accused him of being in "complete solidarity with the most reactionary American professors." The *Guardian* gives the following quotation from an article in *Pravda*.

Zhebrak as a Soviet scientist should have unmasked the class meaning of the struggle which is taking place around questions of genetics. But, blinded by bourgeois prejudices, by detestable fawning on bourgeois science, he has adopted the attitude of the enemy's camp. . . . It turns out there is a so-called pure science for Zhebrak. . . . It appears that there is no progressive Soviet biological science; there is no reactionary biology in the world. . . . How unsightly is the role of Zhebrak!

In a review in *Nature*<sup>3</sup> about a year ago Prof. Eric Ashby, who has visited the U.S.S.R. and conversed with Lysenko, wrote: "As to the present state of the new genetics in the Soviet Union, it is safe to assume that Lysenko's school is well past its zenith." But the *Pravda* attack on Zhebrak suggests that genetics is once again becoming an acute political issue in the U.S.S.R. Indeed, according to an article in *The Times*<sup>4</sup> the cultural curtain between the East and the West is once more to become so opaque—as to justify the description "iron." The Praesidium of the Soviet Trade Union Central Council has issued a decree condemning "adulation and servility towards things foreign and towards the putrefying reactionary culture of the bourgeois West." Russian press articles condemn by name Soviet men of science and inventors "thirsting for praise from foreign scientists and pseudo-scientists." What has happened to geneticists when Russia

<sup>2</sup> Sept. 26, 1947.<sup>3</sup> 1946, 153, 286.<sup>4</sup> Oct. 4, 1947.

is seized with a paranoid psychosis is revealed—we believe for the first time—by Dr. C. D. Darlington, F.R.S., the well-known Cambridge geneticist, now Director of the John Innes Horticultural Institution. In an article published last week he tells a story that can "be told and interpreted on sufficient documentary authority." N. I. Vavilov, subsequently opposed by Lysenko, was appointed by Lenin President of the Lenin Academy of Agricultural Sciences in 1921. During the following twelve years, Darlington writes, "Vavilov's work was one of the most impressive signs of the scientific prosperity of the Soviet Union." Vavilov's work was an inspiration to many Dutch, American, and British scientists. After 1928, under the Stalin regime, Marxist orthodoxy began its ideological incursions into the domain of science. "A Government," Darlington writes, "which relied on the absence of inborn class and race differences in man as the basis of its political theory was naturally unhappy about a science of genetics which relies on the presence of such differences amongst plants and animals as the basis of evolution and of crop and stock improvement." In 1928 a new genetic prophet was found in the person of Lysenko. Vavilov (who had been nominated President of the International Genetics Congress of 1939 in Edinburgh) was arrested in 1940 and later condemned to death—allegedly because of espionage for Britain. When the Moscow prisons were evacuated in 1941 Vavilov was sent to a concentration camp, where he died. Before this the cytologist G. A. Levitzky and his pupil N. P. Avdoulov were sent to labour camps in 1932, and at the same time B. S. Chetverikov, "pioneer of population genetics," and W. P. Efroimson were sent to Siberia. In 1935 the two geneticists I. J. Agol and L. P. Ferry were put to death. In 1937 the head of the Institute of Medical Genetic Research in Moscow, S. G. Levit, was also put to death. Other biologists and geneticists were sacrificed on the altar of the new Russian religion. "In a word," Darlington writes, "after thirteen years of persecution, the great fellowship of Russian biological research, formed in the revolution, had been crushed and broken." And Darlington adds later: "Never before has science offered so many martyrs to its cause, men, too, honoured and beloved throughout the world." Darlington has done a great service to truth in putting these facts on record, facts which many have been uneasily aware of and which some have almost hoped would lie buried in history. For persecution of a similar nature we have to go back to the days of the Inquisition, and such persecution must be interpreted as religious and not political. And we may believe that many men of science and medical men in the U.S.S.R. secretly condemn these acts as strongly as we do openly in this country, where we have the precious liberty to condemn such acts publicly.

It is still difficult to discover just what progress is being made in Russian science and medicine, and the position is obscured by the fact that Soviet propaganda distorts the truth in a way that can only be described as naïve. For example, Prof. Ashby, who was attached as a scientist to the Australian Legation in Moscow in 1944, records in his interesting book *Scientist in Russia*<sup>1</sup> how Prof. Z. V.

Ermolyeva was acclaimed in 1945 as "the discoverer of the new drug penicillin," and Pravda referred to her "greatest discovery . . . Soviet penicillin," adding that it had also been discovered by Fleming. Fleming's penicillin, no doubt, had the demerit of being bourgeois and capitalist. Ashby nevertheless has nothing but praise for "the good Soviet scientist," whom he found to be very well informed on foreign work. Soviet scientists, he said, were eager for contact with workers in other countries—but the Kremlin imposes its veto. Until there can be free interchange of ideas by personal contact between Russian scientists and medical men and their colleagues in other countries ignorance and misunderstanding will prevail. And if the value of a man's scientific work is to be judged in terms of his political faith, as in the strange and tragic story of Lysenkoism, then mutual understanding will indeed be hard to come by.

## ROAD ACCIDENTS

It is many years since public opinion demanded that a man on foot holding a red flag should walk in front of motor vehicles. We laugh now at that precaution, but the alarm felt in those days has been more than justified by the subsequent slaughter on the roads which we complacently accept as a normal part of social life. Just before the recent war there were about a quarter of a million road accidents a year, 6,500 of them fatal. During the war, deaths on the road numbered more than 40,000, or about two-thirds of the total caused by bombing. In 1946, 5,062 were killed. The prevailing indifference to this avoidable loss of life is worth investigation, if only for the reason that measures taken to prevent it require, if they are to succeed, something more than public approval—namely, the active co-operation of all road users. In addition, if there are reasons for people not wishing to pay attention to the problem, a knowledge of them is essential if education and propaganda are to uproot them. Outbreaks of food-poisoning are front-page news; so at the moment is the poliomyelitis epidemic, though its effects will no doubt be numerically far less tragic than those of the year's road accidents. Railway accidents, aeroplane crashes, ships lost at sea, mining disasters, all cause alarm and are investigated by courts of inquiry, yet the lives lost are comparatively very few.

There are two obvious reasons for this disparity of interest: first, the public sees the external cause of the catastrophe—a defective water supply, a faulty signal, a pilot's error. The public itself, or the individual newspaper reader, feels no responsibility for it. Secondly, the impact of these events is enhanced by their suddenly occurring at a particular place and time. On the other hand road accidents concern all road users; responsibility for them cannot readily be attached to a particular person or organization; and, more insidious, they are happening everywhere and every day: they are commonplace. To these two causes of apathy we might add a third, suggested by Dr. Soddy in the lecture printed at p. 623 of this issue.

Many people find driving fast an outlet for their aggression. Directing a powerful machine brings deep satisfaction to minds that cannot control their own powerful and immature instincts. Many people unconsciously share the desire for this form of self-expression, and, though they unconsciously realize its dangers, whether car owners or not they condone it. It is important to investigate motives such as these, for with the modern techniques of propaganda available, by which the unconscious levels of people's minds may be systematically appealed to—for once in a thoroughly good cause—it should not be difficult to arouse enthusiasm for reducing road accidents. It may not be too fanciful to suggest that when a potential suicide crosses a road along which a potential homicide is driving the chance of survival is slight.

The Committee on Road Safety, which was appointed in 1943, has recently issued its Final Report.<sup>1</sup> It believes that the propaganda carried out since the war "has had a good effect," and it advocates the continuance of such measures as well as of education for road safety in schools. It proposes a number of new regulations to control the activities of pedestrians, bicyclists, and motor drivers, and recommends the collection of facts for statistical analysis. It also advises that motor-cars should be subjected to periodic testing at special inspection stations.

The fact that a small proportion of road users are to blame for a large proportion of accidents has been recognized for some years. Psychological tests have been successfully used by private and public concerns to detect "accident-prone" employees, but the Committee sees certain difficulties in using them to eliminate accident-prone drivers. Such tests could not, of course, detect all drivers prone to accidents for psychological reasons, for the man who has a grudge against authority may be as dangerous on the road as a man whose ability to judge distance is faulty; yet he is unlikely to be detected by any psychological test used at present. It would be administratively impracticable to apply intricate tests to all new drivers. If applied to drivers who had been involved in one or more accidents it would be necessary to apportion blame accurately—an exceedingly difficult task. The Committee therefore recommends that further research into the possibility of determining accident proneness by test is desirable.

We have no precise knowledge of the part played by alcohol in road accidents. In 1938 the ratio of motor drivers convicted of being under the influence of drink to other road users convicted of drunkenness in public places was 1 to 19. It is possible that alcohol would more often be found in the victim than in the slayer, if it were looked for. However, according to Sidney Smith,<sup>2</sup> fewer accidents are the result of intoxication than is commonly believed. The Committee advises displaying propaganda on licensed premises, but makes no definite recommendation on the introduction of blood tests. Other points of medical interest are the Committee's proposal—in which they refer to Sir Hugh Cairns's work, an account of which appeared in this *Journal*<sup>3</sup>—that a crash helmet for civilian motor-

cyclists should be developed; and that it is desirable, but not enforceable, that first-aid equipment should be carried on all vehicles. Medical men particularly might bear the latter suggestion in mind.

No single measure will eliminate road accidents, and if their numbers are to be diminished at all we must submit to more restrictions of our personal liberty, whether drivers or pedestrians. A few may ask, Is it worth it? The nation must make the decision, and it can do so only if it is presented with the facts: on the one side the loss of more life, on the other the loss of more freedom. As medical men we must be deeply perturbed by such a cause of death, and also by the amount of work involved in treating such injuries.

### CHOLERA

The cholera epidemic in Egypt is now in its fourth week and in one day recently was responsible for 112 deaths, 7 of them in Cairo. Cases have appeared in Suez and a single notification from Kena suggests that the epidemic, which had been restricted to Lower Egypt, may spread to Upper Egypt. Outbreaks of cholera involving some thousands of cases have also been reported from the East Punjab and Delhi and from other areas where a mass migration of refugees is now taking place. In India cholera takes a heavy toll of human life every year, especially in the Ganges valley. Fairs, religious festivals, and political gatherings are only too often the scene of great outbreaks of cholera in a land in which flies abound and where drinking of the heavily polluted water of sacred rivers and ponds is a necessary religious rite. In the Punjab the recent floods have further contaminated existing water supplies, and sanitary arrangements and, indeed, habits are almost non-existent.

Clinically cholera varies in intensity from a mild diarrhoea to the fulminating form with early collapse and death from intense toxæmia. Untreated cases have a mortality rate of from 80% to 5%, the latter figure being found towards the end of an epidemic. In evaluating new methods of treatment it is therefore necessary to treat large numbers of patients of approximately the same age and social status at the same stage of the same epidemic, giving the treatment under trial to alternate cases only. In the early part of this century Sir Leonard Rogers introduced his well-known fluid-and-salt-replacement treatment in Calcutta. This still remains the basis of treatment to-day. Even in mild cases there is marked depletion of the blood and tissue fluid volume and loss of the essential salts. Marriott's recent Croonian lectures<sup>1</sup> demonstrated clearly the urgent need for a general understanding of the principles involved. Cholera is an outstanding example of rapid water and salt depletion, with the addition of a severe toxæmia produced by the vibrio.

The recognition by Rogers so long ago of the importance of water and salt replacement in cholera has saved countless lives, but the need for a minimum amount of apparatus and for skilled attendants has led to the treatment being carried out imperfectly in small towns and often not at all in rural areas. Many a devoted missionary in India and China has performed wonders with a teapot, a piece of rubber tubing, a hollow needle, and water drawn originally from a village well. To obtain the best results, however, hospital conditions are desirable, with adequate facilities for sterilizing large quantities of pyrogen-free water, for keeping constant watch on the blood pressure and the specific gravity of the blood, for measuring the output of urine, and for disposing safely of excreta. The use of a

## THE HARVEIAN ORATIONS, 1656-1947

## A STUDY IN TRADITION

BY

W. J. BISHOP, F.L.A.

AND

F. N. L. POYNTER, B.A., F.L.A.

(From the Wellcome Historical Medical Museum)

The first Harveian Oration was given by Dr. Edward Emily in June or July, 1656, and the 233rd will be delivered by Dr. C. E. Lakin on St. Luke's Day, Oct. 18, 1947.

The Harveian is one of the oldest and probably the most widely known of all the many eponymous orations and lectures connected with the medical institutions of Great Britain.

William Harvey gave to the College of Physicians during his lifetime his patrimonial estate of Burmarsh, in Essex, then valued at £56 a year. In the deed of trust dated June 26, 1656, he directed that "once every year there shall be given . . . an oration in Latin publicly in the said College, wherein shall be a commemoration of all the Benefactors of the said College by name . . . with an exhortation to the Fellows and Members to search and study out the secrets of Nature by way of experiment." An honorarium of £5 was to be paid to the Orator, and only in 1939 was this raised to ten guineas. For many years it was apparently the custom to nominate as Orator the most senior of the Fellows who had not held the office, but latterly the appointment has been made on other grounds than that of mere seniority. The actual appointment, which was originally vested in the President, the two senior Censors, and the two senior Elects (an order which died out in 1860), is now made by the President alone.

There are gaps in the yearly sequence of Orations, for in the first fifty years of its existence only twenty were delivered and only seven published. The last fifty years, on the other hand, presents an unbroken continuity, in spite of the two most disastrous wars in the world's history; but the second of these did force the College to make one great departure from tradition when Sir Edmund Spriggs delivered his Oration at the Royal Infirmary, Manchester, on St. Luke's Day, 1944.

## A Few Interesting Facts

In earlier times Fellows were not infrequently called upon to deliver the Oration more than once. Two Harveian Orations were given by each of the following: Samuel Collins (1665, 1682), Charles Goodall (1694, 1709), Anthony Askew (1758, 1762), William Cadogan (1764, 1792), Sir Henry Halford (1800, 1835), and Sir James Alderson (1854, 1867). Walter Charleton was Orator three times, in 1680, 1701, and 1705, but the record is held by Walter Harris, with four Orations, delivered in 1699, 1707, 1713, and 1726. Charleton thought it a fact sufficiently remarkable to mention on the title-page of his second and third Orations that his age was 81 and 85 respectively at the time of their delivery. As contrast to this is the extreme youth of others, such as Charlton Wollaston, who was Harveian Orator (1763) at the age of 30 and died a year later.

Some very interesting sidelights on medicine as a hcredit profession emerge from a study of the list of Orators. Willi Heberden the elder was Orator in 1750 and his son William 1809; John Latham in 1794 and his son Peter Mere in 18; Richard Warren in 1768 and his son Pelham in 1826; Geo Rolleston in 1873 and his son Sir Humphry in 1928. Sir Russell Reynolds (H.O. 1884) was the grandson of H. Reynolds (H.O. 1776), but the most extraordinary instance provided by the Monros, four generations of whom gave Oration: James (1737), John (1757), Donald (1775), and Edw Thomas (1834); moreover, all four were noted alienists and held the office of Physician to Bethlem Hospital.

Of the 232 Orations known to have been given since 1656, have been printed, either separately or in a medical journal. The more recent are common enough, but some of the old Orations are very rare. They were divided by Osler into three groups: (1) Those which simply fulfil Harvey's injunction (2) real contributions to the literature of the physiology of

circulation; and (3) those which the Orator, after a preliminary words of praise discourses upon the work which he is most interested in. Not all of them fall naturally into one of these groups. At various times, especially in the period 1750-1850, the Harveian Oration fulfilled many of the functions of the Presidential Addresses, which were given regularly until about 1870. In addition to the praise of benefactors many Orators comment on current trends in medical politics and education and include obituary notices of tributes to Fellows recently deceased. Several Orators have made valuable contributions to the biography of Harvey or the history of the discovery of the circulation. Among the best Orations in this respect are those of Sir H. Acland (1865), Sir G. Paget (1866), Owen Rees (1869), T. K. Chambers (1871), G. Rolleston (1873), Sir E. Sieveking (1877), J. Ogle (1880), Sir H. John (1882), Sir J. R. Reynolds (1884), J. F. Payne (1896), R. Crawford (1919), H. Spencer (1921), Arnold Chap

(1922), Sir W. Hale-White (1927), Sir H. Rolleston (1928), and Sir W. Herringham (1929).

The Oration has been delivered by some "so obscure as to make their appointment to that post their only claim to fame and by men of such reputation as to make it their smallest task to distinction." The names of Akenside, Arbuthnot, Galen Mead, Heberden, and Baillie are known to all; but who has heard of John Hawys, Charles Bale, Robert Hopwood, and Charles Feake?

## Some Early Orators

The first Oration, that of Edward Emily (1617-57), was delivered some time between June 21 and July 28, 1656. The text has not survived, but Emily is said to have expressed himself a little too freely on the subject of the Army and the Commonwealth, a dangerous topic in 1656, and a vote of censure was passed and duly recorded in the Annals. Indiscretion led to the ruling that all future Orators submit their papers to the President for his approval, but this has long been ignored.

The second was given by Edmund Wilson (c. 1615-57) in June, 1657, a few days after the death of Harvey. It was published, but it is known that Wilson took the opportunity to deny the spreading rumour that Harvey, to lessen his suffering, had hastened his death by taking opiates. It is a curious

Title-page of the first printed Harveian Oration

coincidence that the first two Harveian Orators died within a few months of fulfilling their office.

Daniel Whistler (1619-84), the third Orator (1659), is remembered for the first clinical description of rickets. He held in succession the offices of Registrar, Treasurer, and President of the College, not entirely to the advantage of the College funds, and his conduct was censured in the Orations of Walter Harris (1707) and John Hawys (1721); but his friend Evelyn thought him "good company and a very ingenious man." Thomas Cox (1615-85), Orator in 1660, is warmly referred to by Thomas Sydenham as "the patron and promoter of my first endeavours."

The fifth Oration, that of Sir Edward Greaves (1608-80), delivered on July 25, 1661, was the first to be printed. It appeared as a slim quarto of 32 pages in 1667. According to Sir Norman Moore, it "contains a few facts and many conceits, but some of these are happy. He says that before Harvey the source of the circulation was as unknown as that of the Nile, and compares England to a heart, whence the knowledge of the circulation was driven forth to other lands." The original manuscript is in the British Museum (Sloane 302).

The sixth Orator, Nathan Paget (1615-78), was the familiar friend of Milton, and among the guests at his Oration was John Evelyn, who records the fact in his Diary. Let it be recorded to the honour of Samuel Collins (1617-85), Orator in the Plague Year of 1665, that he was one of the physicians who remained in London throughout the epidemic. Happily, he survived to deliver the Oration a second time, in 1682.

#### Notable Orations

There are many remarkable features about Richard Mead's Oration of 1723. Not only was it the first to appear in an English translation (1763) but a French version appeared as late as 1774. The Oration proper, a brief argument in defence of the status of the physician in Greece and Rome, has been confused by eminent medical historians with the *Dissertatio de nummis* with which it was first published. This illustrated essay on ancient medical coins was not even Mead's own work, but that of Edmund Chishull, divine and antiquary (1671-1733). Mead's remarks on the high prestige of the ancient physicians led to a "pamphlet war" with Conyers Middleton, the Cambridge antiquary. In 1761 the elder Heberden found among the Harleian MSS. a final unpublished "Defensio" of Middleton's in which Mead was referred to in the most generous terms. He had a "few copies printed to be given away," and so publicly vindicated the honour of the medical profession and of one of its staunchest champions. The Oration (1751) of the eccentric Sir William Browne (1692-1774) is one of the finest from the typographical point of view. It has a handsome engraved title-page and the first page of the text bears a head-piece representing the Sheldonian Theatre at Oxford, the Senate House at Cambridge, and a view of the old College of Physicians in Warwick Lane. The Oration of Robert Taylor (1755), one of the most polished and elaborate of any, was the medium for disseminating the favourable opinion of the College with respect to inoculation for smallpox.

#### Contemporary Comment

With the rise of the medical journals in the early part of the nineteenth century we are provided with a wealth of contemporary comment on the Orators and their Orations. These are always interesting and sometimes startling. Thus, the *Lancet* of June 29, 1833, records that "the Harveian Oration was delivered at the College of Physicians, Pall Mall East, by Dr. Paris, on Tuesday afternoon last. It consisted of the usual twaddle uttered on such occasions. The meeting ended in a jollification, and the proceedings have been duly recorded in the theatrical portion of the columns of the daily journals."

Perusal of John Elliotson's Oration of 1846, which is a veritable apologia for mesmerism and for his own conduct with regard to it, recalls one of the bitterest episodes in British medical history. The Oration was delivered in Latin, but in order to give his views wider publicity Elliotson had it published in both Latin and English versions simultaneously. Apart from topical references to the cholera epidemic of 1849 (Wilson, 1850), the Crystal Palace (Spurgin, 1851), medical politics

(Alderson, 1854), and the Indian Mutiny (Wood, 1858), there is little of note in the few remaining Latin Orations. The last of these to be printed was that of A. J. Sutherland in 1863, and in the following year Robert Lee delivered the last Oration in Latin. This was not printed, but the original manuscript is preserved in the College Library.

Sir Henry Acland in 1865 made the final break with tradition by delivering and printing his Oration in English, and since that date no Orator has ventured to use the Latin tongue. The effect of this has been to instil reality into what had become a rather stultified performance, and the fine series of English Orations since that date contain many valuable observations on the advances made in physiology and clinical medicine, for of recent years Orators have taken the rational course of departing boldly from the somewhat narrow bounds laid down by Harvey in 1656, a course of which the great experimenter would surely have approved.

We are indebted to Dr. E. Ashworth Underwood, Director of the Wellcome Historical Medical Museum, for permission to reproduce the title-page of the very rare Harveian Oration of Sir Edward Greaves from the copy in his care.

## PSYCHOLOGICAL ASPECTS OF ACCIDENTS AND ACCIDENT PREVENTION\*

BY

KENNETH SODDY, M.D., D.P.M.

Medical Director, National Association for Mental Health

Up to now there have been few organized attempts to understand either the emotions and instinctive impulses underlying road accidents or the social forces involved. Perhaps we have not sufficiently regarded accidents as an integral part of our community life. There is a temptation to regard them almost as interlopers, and it may be for this reason that they have not been studied systematically in their natural setting in the community.

Laboratory experience has demonstrated some relationship between accidents and fatigue, lack of experience, and poor general health. Road accidents, in particular, tend to occur more commonly among drivers who are not in good health or who are unskilful, among older people and the inexperienced young drivers, and among those with delinquent records. It is noticeable that nearly all these classes include complex combinations of human attributes or influences. Then there is so-called "accident proneness" to be considered. Scientific studies of drivers showed in one case that 10% of a group of drivers was responsible for 60% of all its accidents; and in another that 20% of the drivers had an accident rate 3½ times as high as the remainder. Certain laboratory tests of quickness of reaction and of muscular co-ordination have shown that poor performance in the tests was four times as common among the accident-prone group as among the remainder. Less decisive correlations were obtained with tests of intelligence and of temperament.

Accident proneness is related to lack of quickness, slow reaction time, poor muscular co-ordination, poor intelligence, instability of temperament, and distractibility. Once again, every one of these factors is complex and by no means constant in each individual all the time. For example, what is meant by instability of temperament and distractibility? During the recent war, when the Army had to select many thousands of men to become drivers, it was found that a combination of laboratory tests with careful assessment of past history and of present temperament achieved an encouraging success in reducing both the period of training and the occurrence of accidents during training. On the whole, men and women of under 40, with good civil records, a healthy attitude towards military service, with average intelligence, enjoying good health, and who did well in the tests, were the most successful. However, this type of person is wanted for every other responsible job, and

\*Abridged from a paper read to a joint session of the Safety Education and the Home Safety Sections of the Royal Society for the Prevention of Accidents' Silver Jubilee Congress at Brighton on Oct. 8.

perhaps common sense would have got us as far. But much has been learnt in establishing even this piece of exact knowledge.

One large-scale inquiry into the causes of military road accidents over a period of six months failed to reveal any accident-prone drivers, but it may be that the period of time was insufficient. It did reveal certain accident-prone military units, and this observation opens up a whole new field for speculation: Why is it that certain groups of men are more liable to accident than others working under identical conditions?

### The Sociological Approach

Accidents need to be studied as social events. They occur as integral parts of our daily life in the community; we expect them and make provision for them, and they are as much social events as any other happening in the group. Practical difficulties arise out of the need to study large numbers of people in order to provide enough accidents from which to draw conclusions, to keep them under notice for a long time, to study relatives and friends of the principals, and to study the onlookers. Moreover, the public dislikes being studied; which means that any project will need to be introduced with great wisdom and care.

The tests of temperament and emotional stability used up to now have mostly been of a static, question-and-answer type and have not given decisive results. The method of study needs altering to include a systematic study of the emotional life of participants and their past history up to the critical moment when they all converged for the final drama. The onlookers (the people in the street) must not be left out, for they were present and may be an influence to be reckoned with. Lastly, and most important, our study should include facts and ideas not only as they appear to a dispassionate outside observer but as they appear to the people involved in the accident themselves. Fantasy plays a large part in the lives of most of us; and fantasy distorts objective reality all the time and in ways that few of us clearly appreciate.

The differences in attitude shown by pedestrians, motorists, and cyclists owe much to distortion by fantasy. Therefore it is vitally important to learn more about what being on the road does to the individual who is walking, driving, riding, or merely standing and looking on, and to find out how road users influence each other. Much can be learnt by studying children, whose component forces are apt to appear with less concealment than those of adults. It is easy to see how the natural properties of childhood lead to danger. This subject was dealt with by Dr. Susan Isaacs in a paper read to the Royal Society for the Prevention of Accidents in 1938, and I cannot do better than paraphrase her main conclusions.

### Child Psychology and the Road

Isaacs drew attention to the adventurousness of young children, their impulsive curiosity and need to gain mastery of things. They possess a relative lack of prudence and forethought, a span of attention too narrow to take in all the details of a crowded street, and a rudimentary perception of space and time—i.e., they cannot estimate the speed of an oncoming car.

Other observers have noted the child's lack of understanding of mechanical cause and effect and of impersonal events: to a young child the wind is a person or is blown by a person; he endows all outside happenings with a personal and often human significance.

Dr. Isaacs observed that toy cars and trains are used by young children to symbolize their parents and friends and often their own feelings. The boy who crashes his toy car noisily into his sister's doll's-house symbolizes a wealth of feeling. From this it is only a short step to the child's endowment of real vehicles on the road with his own feelings or with the attributes of his parents. For him traffic may represent formidable objects of great power—like Daddy when he is angry, or his own internal feelings of anger which are so terrifying to him.

Dr. Isaacs pointed out that children make a positive contribution to their own danger. The child's normal sense of helplessness contributes to bravado: he must test himself and the traffic (which may symbolize his fantasied fears). The child who is unsettled or insecure or basically not happy in his

relationships at home is particularly prone to bravado, to suspicion, or to test out whether the oncoming car (which may represent a parent) will respect him or not. He may wish to defy, attack, or annoy the motorist, who in the child's mind may not be clearly distinguished from the policeman or a fussy mother. Even more than this: there may well be a real and deep desire to be hurt. Just as some children attract bullying, others invite punishment. In human nature, the not uncommon impulse of a child to displace his parent is followed by a great sense of anxiety and guilt—traditionally in mythology, usurpation of the father's position is punishable by death.

What happens if a young child by the side of the road has a sudden impulse to defy a car because in fantasy it represents his own father? The situation is potentially dangerous, and it becomes more so if the impulse is as quickly followed by remorse, by a desire to throw himself at the mercy of the car or even to invite punishment. It may be argued that this line of thought is leading us into deep waters, but such mechanisms and symbolical actions are not uncommonly encountered in disturbed and maladjusted children. Dr. Isaacs sums up the situation with moderation by remarking that some children have deep impulses stronger than their powers of intelligent control.

The importance of admitting the possibility of these childish mechanisms lies in the way such attitudes tend to linger on and influence adults in strangely uneven and unexpected ways. Most grown-ups are aware of little islands of childishness within themselves; many will pride themselves on retaining some of the magic of childhood. This state of incomplete maturity or lack of perfect balance makes it doubly important to recognize that reason and conscious knowledge do not govern everything; and that accidents should be understood, if possible, not only in their total social setting, but also in terms of what they really meant to the participants and what the parties meant to each other in fantasy as well as in fact.

### Type of Inquiry Required

A few weeks ago, in a quiet side-street in St. Marylebone, an elderly lady began to cross the road in a slow, rheumatically manner about midway between two pedestrian crossings set 100 yards apart. Just at that moment the traffic lights across Baker Street, 50 yards away, flashed green, and an open, cigar-shaped sports car with no mudguards roared into our street, driven by a youth of about 18. As a fellow pedestrian my personal sympathies were with the old lady, though the stickler might assert that she should have dragged her rheumatically self 50 yards to use the pedestrian crossing. The youth had ample time to apply his brakes partially and slide gently behind the old lady, but he delayed action until the last moment, stamped on his brake and pulled up violently with brakes and tyres screaming, exactly behind her. He put out his head and said something unkind, audibly rammed in his gear lever, and went off in a roar of indignation. The old lady looked round vaguely and went on her way without comment.

There are many questions urgently requiring answers—e.g., did having control of a car make any difference to that young man? Was this a sample of his normal behaviour? What was his relationship to his mother? What did the old lady mean to him, if anything? Did she symbolize for him at that moment his own mother, or perhaps authority in general? Was he inflicting on the head of an innocent substitute all the hostility stored up against another person to whom he dared not appear as he felt? Was his behaviour merely due to irritation at the interruption of a dream of power and speed which he was deriving from his car? Again, is a sports car in the hands of a young man more dangerous than a saloon car of equal power? Thirdly, were the onlookers being asked to witness the prowess and cleverness of this young man? Would it have happened had they been alone in the street? Fourthly, was the old lady really as ignorant of wise behaviour on the road as she appeared to be? Did the young man perhaps symbolize anything to her—her own son, or something unpleasant? Had she any personal reasons for courting danger or death?

It would be foolhardy to dismiss this incident merely as boorishness on the driver's part meeting stupidity of the old lady. To do so would prevent any possibility of ever coming to understand causes. But there is one other unanswered

question which seriously reflects on the present state of our knowledge: Does this kind of happening bear any relation to accidents proper? One feels that both parties are of the stuff of which accidents are made, but there is no proof of this.

### More General Aspects of Behaviour on the Road

There are more general inquiries besides intimate studies: what effect has driving a car on the ordinary man and woman? and what effect has facing an oncoming car? We know that cars symbolize power without effort, speed, adventure, exploration, and independence—all characteristics more in line with male psychology than with female. Is there, after all, a genuine difference between men and women drivers, as misogynists maintain? It needs exact investigation. If a car ministers to a young man's sense of power and his more animal characteristics, is our friend in the sports car the modern equivalent of the classical centaur, with the head of a man and the body of a horse and behaviour compounded of both (but without the centaur's intellectual propensities!)? Some women feel this instinctively and sense that driving a car is in some way a threat to their femininity. Such women are apt to treat their cars as dangerous animals needing strict control.

The implication of all this may be that people react to driving in a similar way to their reaction to their own instinctive and emotional impulses—a principle that applies equally well to pedestrians and cyclists. The mature, well-balanced person faces the road without a qualm; he estimates the danger accurately and is confident of his powers to cope with it. He also faces his social responsibilities squarely. The immature, unstable person reacts not only to the traffic but at the same time to his own fantasies of violence, aggression, fear, and power as symbolized by the traffic. Consequently, the likelihood of the unstable person doing foolish and inappropriate things is greatly increased. It is probably fair to conclude that road accident prevention is intimately bound up with the broad principles of mental health to a degree far greater than is generally realized in both its personal and its social aspects.

### Practical Applications

One practical result of demonstrating the deeper emotional significance of accidents may be to show that a high proportion of so-called accidents not only are deeply motivated but also fit into the life pattern of one or more members of the group. The next task is the more accurate prediction of dangerous emotional forces, and I believe that at last psychologists possess techniques of investigation to enable them to undertake the task profitably. The chief deficiencies are money and a clear mandate from the public to go ahead.

It is time for a series of large-scale investigations on carefully chosen sections of the community into the psychological forces behind every accident in their individual and group significance, both real and arising from fantasy. This would involve studying a great number of people and could scarcely be completed on a voluntary basis. Whether it would be possible to get the same statutory powers to investigate as for rail and air accidents is very doubtful, but it may be necessary to seek these. This investigation would be very unpopular with the public unless presented to them with great care, and to do it well would involve expenditure of much time and labour. We must weigh these depressing considerations against the continued and appalling loss of life and destruction at present. The public conscience is dulled by the very fact that road accidents are so commonplace.

### Safety Education

This suggested investigation would quite possibly lead to the prevention of accidents at their source so far as the "human elements" are concerned; but this is a long-term aim which would not easily be reached. A more immediate effect would be on the propaganda and public education campaigns. It is difficult confidently to direct educational work without exact knowledge of the dynamic forces involved.

Nowadays much stress is laid on "training children to obey," the modern feeling being that though children will no longer obey at once for authoritarian reasons (if they ever did), they can at least be trained to obey (if the educator is cunning enough) as a kind of conditioned reflex. It is often hoped that

obedience and road sense can be so instilled by maxims as to become part of the child's second nature. For instance, by harping on danger it is hoped that automatic avoidance of danger will result. Quite apart from the fact that, psychologically speaking, this is a very doubtful proposition indeed, avoidance of danger is not the real aim, which is more fundamental—namely, to strengthen the positive factors on the side of safety and to remove morbid motives leading to the active seeking of danger.

Much of safety education still relies on authoritarian and horrific methods, both of which are effective in reasonable doses with well-balanced children but positively dangerous with mal-adjusted and unhappy children. The former method challenges children to defy authority; the latter challenges them to dare to test out the fear aroused. Not only children but many adults react unhealthily, and no one can estimate the potential damage of these methods. Similarly, repetition can be overdone. A report issued some time ago by the L.C.C. said that safety education required "damnable iteration." If the iteration really were damnable it is a safe bet that the results would be equally damnable.

### Road-safety Films

A recent inquiry into the effect of three road-safety films raises certain points of importance to the whole field of safety education. This inquiry was made by the Tavistock Institute of Human Relations at the request of the Petroleum Film Bureau, to whom I am indebted for permission to quote the results. The investigators aimed at spontaneous expression of attitude by children divided into groups of ten and engaged on chalk drawings, completion of stories, making up games and plays, and discussion, before and after seeing the film.

It appears to be very relevant to the success of the film—or, indeed, possibly to the success of any other educational technique—whether the children are able to enjoy it freely, express criticism openly, and join in discussing its story and problems afterwards; all of which will affect the amount of assimilation and change of attitude. It may be risky to generalize, but those children from stricter schools reacted less unfavourably to the didactic or direct teaching sequences of the films than those from freer schools. I have deliberately used the expression "less unfavourably" because it is not sufficiently recognized that normal children not dragooned by rigid discipline react in a hostile way to being talked down to, which may go far to explain many difficulties experienced by some teachers in schools.

It is striking that the children's own ratings of the three films were in reverse order from those of an experienced adult reviewer, who failed to recognize the strongly negative or hostile reactions which parts of the films evoked in the children. The latter responded by mistrust to being talked down to and by resentment to seeing a child depicted who was obviously foolhardy. Their hostility was shown by open criticism, by rejection, and by omission from play and story-making. They also appeared to try to get even with the adults by being very critical of all the small technical mistakes which they noticed.

The films revealed the possibilities of an effective indirect approach by stimulating thought about social problems arising out of the film—e.g., playing on bomb sites, the lack of playing space, co-operation with motorists in quiet roads, and so on. Such thinking and discussion may be more fruitful than even a direct teaching technique.

The report of the Tavistock Institute of Human Relations recommends that films be used as preludes to discussion, games, and other spontaneous play activities in which children can work out their own ideas about road safety. In particular, direct teaching sequences and pointing the moral should, if wanted, be left to the teacher and not incorporated in the film.

*An Indirect Approach.*—The observation that the films indirectly stimulated interest in such topics as playing-fields for crowded areas leads to the speculation whether good results could not be obtained by showing story or narrative films of everyday life in which the road-safety theme appears as an incidental sequence; then, by the discussion-play technique, to work on the ideas stimulated in the children—a possibly difficult but theoretically sound and promising technique.

### Some Psychological Ideas on Educational Methods

Can some of the findings of the film inquiry be applied in principle to other methods of safety education? The primary aim is to harness, as it were, the child's sense of responsibility; to make him whole-heartedly on the side of responsible behaviour, not merely as a sense of duty imparted by parents and teachers, with the jungle half of him in rebellion, but heart and soul. Our greatest natural ally is the child's own desire to grow up. Methods which place responsibility on the shoulders of children in a way which they can bear are the safest means of conveying ideas that are charged with emotion; finding out for themselves by play is one example of such a method. Didactic, dogmatic, or direct teaching methods are the least satisfactory for conveying emotionally powerful ideas such as discipline, danger, and death.

The negative aim of avoiding provoking hostility is at least as important as the more positive aims. Hostility may be aroused by the ideas themselves, by the method of conveyance, and by the person conveying them, and when aroused tends to irradiate the whole subject, thus leading to an increase in danger to the unstable child.

The ordinary straightforward classroom teaching method is probably best kept mainly for factual education and for invoking the child's reason and sense of responsibility. This method is less effective for dealing with the dangerousness of roads or for presenting the antithesis between safety and danger, if only lest we succeed too well and persuade the children that the aim of man is to be safe and to avoid danger. The facts and statistics of danger, presented reasonably, can be handled by direct instruction. There is also an ample field for classroom methods in combating the often surprising ignorance of why traffic exists and of the part it plays in everyday life. Few children realize how dependent they personally are on the free and safe circulation of vehicles on the roads and of the roles of traffic regulations and policemen. We also need greater widespread knowledge of how vehicles work, of what they can and cannot do, of the limitations of the driver, and of what the road looks like to the driver compared with the pedestrian. There is nothing new in this; many authorities have been using these methods for years.

Such teaching must take care to avoid moral judgments suggesting that it is "good" to obey traffic rules and "bad" to dart into the road. In teaching, to link road behaviour with morals is to risk a negative overstress, especially from the unstable child, and may, like over stressing the horrific, actually increase the danger to that child.

Ideas of emotional importance such as danger, damage, injury, death, and bereavement lend themselves to a more indirect technique by films, plays, discussion, and the spontaneous production of ideas by groups of children. Just as accidents often come in the social group, so it is reasonable to seek their prevention by group as well as by individual methods. In particular the moral ideas associated with road behaviour—and all behaviour has inescapable moral implications—are best left to spontaneous evolution by the children themselves.

### Conclusion

Good safety education achieves much, and in principle what has been said here will apply also to adults, and in the home and factory. When education has harnessed to it all the knowledge which could be acquired from an investigation into the inner emotional implications of accidents and their significance to the social group, who knows how much more could be achieved? That is why so much emphasis has been laid throughout this paper on the need for a new approach before the full contribution of psychology to the prevention of accidents can be realized.

The shortage of doctors in Berlin has caused the Allied *Kommandatura* to authorize the city *Magistrat*, according to a report in *The Times* of July 26, "to set up a committee to deal with the applications of medical men who have been convicted of criminal offences to be re-registered to the register." The applicants must first have served their terms of imprisonment.

### FOOD AND DRINK INFECTIONS

#### Conference of Representatives of Local Authorities

A conference of representatives of local authorities of England and Wales and Northern Ireland, including the chairmen of members of health committees, medical officers of health, and sanitary officers, was summoned in London on Oct. 9 by the Central Council for Health Education to discuss food and drink infections.

Lord Woolton, the chairman, said that there were between 1,500 and 2,000 deaths annually in England and Wales due to bovine tuberculosis conveyed by infected milk. When he was Food Minister he had spent many anxious weeks investigating this problem, and had come to the firm conclusion, from the evidence available to a Government department, that there ought to be compulsory pasteurization in this country. Was it too much for local authorities to accept the same standard of responsibility for the milk consumed in their areas as they already accepted for water? The large number of deaths of young children from diarrhoea and enteritis was also lamentable. Most of these deaths were due directly or indirectly to food or drink infections. A message was then read from the Minister of Health in which he stated that the information obtained by his department made it ever more clear that a great part of infection could be avoided by scrupulous attention to cleanliness in equipment, clothing, and person at all stages of manufacture and handling of food and drink.

#### The Problem Stated

Sir William Savage said that in some cases, as with staphylococcal infections, the reservoir of infection was from human sources; in others, as in the *Salmonella* group, it was derived from animal sources, particularly pigs, ducks, and small rodents, while in the case of botulism the organism was in the soil. The greater the manhandling of food the greater the likelihood of infection. Outbreaks of food-poisoning arose rarely from pork, but much more often from ham, which was handled more. He had frequently come across cases in which a food as originally prepared was perfectly harmless, but had become poisonous after a lapse of time because it was left at a temperature which encouraged the rapid multiplication of organisms. Food-poisoning the source of which was a diseased animal was not very common; he recalled that the first outbreak he ever investigated, forty years ago, was due to brawn from a pig which was so ill that it had to be carried to the place of slaughter in a milk float. Much had been done under Lord Woolton's administration to concentrate slaughtering in a selected number of slaughter-houses, some 500 instead of the former thousands; but it was now time that these selected slaughter-houses, which were often cramped and difficult to supervise, were all made really satisfactory premises.

The growing popularity of communal feeding-places, Sir William Savage continued, while advantageous from many points of view, had its disadvantages. Washing-up arrangements were often far from satisfactory. There were too few tanks, and the tanks were not kept to their assigned purposes—one for washing and another for rinsing. Utensils were in short supply, and often went back into circulation after perfunctory cleansing. The choice and strength of detergents were important, and the temperature of washing-water was a point too often disregarded. Food when prepared must be kept cool in refrigerators working at the proper temperature. Medical examination of all food handlers he considered to be impracticable, for if it was superficial it would be of no use, and if elaborate, involving bacteriological examination of stools and so forth, it would be prohibitive in cost. But it should be a condition of licence of any premises where food was consumed or sold that all cases of illness among the staff were reported to the medical officer of health.

#### Varieties of Infections

Dr. G. S. Wilson, director of the Public Health Laboratory Service, said that the number of food-poisoning outbreaks reported annually was now some 500, about a sevenfold increase since before the war. Bread was a very uncommon

## *the* **NEW analgesic...**

First reports on the use of 'Physeptone' in general practice indicate that an outstanding advance has been made in the treatment of severe pain. With few exceptions, it may with advantage replace morphine, to which it is equal or superior in analgesic effect. 'Physeptone' does not unduly depress respiration, constipate, or induce narcosis or mental apathy; it may be given continuously for long periods without diminution of effect.

'Physeptone' is available in ampoules of 10 mgm. in 1 c.c., in boxes of 12 at 9/-, plus 1/1½ purchase tax. For oral administration it is available as 'Tabloid' brand compressed products, 5 mgm., in bottles of 25 at 4/6, plus 7d. purchase tax, and bottles of 100 at 16/10, plus 2/1½ purchase tax.

## Nutritional safety during weaning

As the infant's introduction to solid food, and as a basis of the diet during the subsequent months, there is no more suitable preparation than Farex. The usual starchy predominance of cereals is balanced in Farex by an increased proportion of protein; in addition, Farex supplies minerals—assimilable iron, calcium and phosphorus—and a useful amount of vitamin D (1,000 i.u. per oz.). With Farex and milk as the staple ingredients, weaning to solids is reduced to its simplest and safest terms. Please help to ensure sufficient Farex for weanlings by advising it only for them.

### PREPARATION FOR A MASTERPIECE

"THE only solution that gave virtual disinfection with great regularity in 15-20 sec. was 2 per cent. iodine in 70 per cent. alcohol, the virtues of which are well known and have been upheld by many investigators. . . . This then is the ideal disinfectant for needle puncture, when great rapidity is essential. It seems that for surgical incisions also a single painting just before the operation is all that is necessary, and that elaborate washings and other preparation of the skin could be omitted. . . ."

"Rapid Chemical Disinfection of Clean Unwashed Skin," LANCET, May 11, 1946, pp. 683-686.

This is one of the classic papers relating to the antiseptic value of iodine. All the research literature is collated and made readily available to members of the medical profession by the Iodine Educational Bureau. Many of the newer iodine uses and research findings are not widely known. Medical practitioners are invited to consult the Bureau about them.

**Iodine Educational Bureau**  
19 STONE HOUSE, BISHOPS COTE, LONDON, E.C.2

urce of infection, because most bacteria would not grow on a crust of the loaf. Fresh meat, freshly cooked vegetables, and cereals were seldom implicated. The dangerous foods were milk and milk products, cream, synthetic milk, ice-cream, custards, jellies, and trifle, all of which contained nutrient substances for bacteria. Another group of dangerous foods included brawn, pressed beef, stewes, and sausages. Gravy, soups, sauces, and shellfish were occasionally responsible. The danger lay in the preparation of foods beforehand, and in serving them under conditions suitable for bacterial growth, often in a warm kitchen.

Mr. L. H. Lampitt, director and chief chemist of the laboratories of J. Lyons and Co., Ltd., gave an account of the methods of control employed in a great catering firm and the efforts made from every side to ensure cleanliness and wholesomeness. He mentioned that during more than twenty years of war and peace Lyons had never been involved in any major food epidemic, although they employed approximately 20,000 people directly in the manufacture, preparation, and serving of food, and served nearly half a million meals a day. At present food catering encountered many difficulties, and he pointed out the danger of accepting things to-day as normal and basing policy on them.

### American Practice

Some account of food and drink hygiene in the United States was given by Dr. Robert Cruickshank. He said that since 1942 the United States Public Health Service had inaugurated courses of instruction for food handlers in many different industries. They had also set up a code with a useful series of regulations, going very much further than anything available in this country at present. The code established certain standards for the handling of food, medical supervision of food handlers, and refrigeration. In this country under the Food and Drugs Act, 1938, there were certain regulations, but these were concerned only with actual buildings and there was very little applying to the food handler himself. Dr. Cruickshank also drew attention to the need for a better system of food storage, and even under present conditions he pleaded for a great extension of refrigeration, particularly for the communal kitchen. The United States in this respect was very much ahead of us, in that refrigeration, both communal and domestic, had been established there for many years, and refrigeration of every kind of food in communal kitchens was a routine.

Dr. Robert Sutherland, medical adviser and secretary of the Central Council, said that there were three major problems: bovine tuberculosis due to infected milk; diseases like typhoid and paratyphoid, and notifiable food-poisoning; and, finally, diarrhoea and enteritis, which caused between 3,000 and 4,000 infant deaths a year. The problem of milk was an administrative one, but it had its educational side in bringing home to people the need for heat-treatment of milk. Public health authorities, pending compulsory pasteurization, should insist upon the boiling of all milk consumed by children in their area, except possibly the milk which came from T.T. herds. With regard to food infections which were the result of some fault in production and distribution, legislation should be reviewed with the object of setting up a code of requirements similar to that established by the U.S. Public Health Service. The Board of Trade should help to meet the requirements of the food-handling industry for equipment and materials to ensure cleanliness and safety. The problem of infantile diarrhoea and enteritis was more complicated because the sequence of events was less obvious, but it was important to make an approach to the housewife concerning the possible conveyance of infection, particularly in homes where there were young infants.

### A Comprehensive Programme

Dr. Sutherland went on to say that standards of food-handling, with many commendable exceptions, were low. Many popular restaurants would lose their patronage if only a glass partition separated their dining-halls from their kitchens. The key people were the local authorities and their officers. Committees should be set up in every area to investigate the local position and to take action. Conferences should be

arranged, with representatives of the medical and nursing professions, the food-handling industry, educationists, leaders of industry and the workers, women's institutes, and youth organizations.

The Central Council for Health Education was prepared to assist in any effort along these lines. Experts were available to give courses of lectures. A two-tier attack was necessary: the first directed to the supervisors and workers in the industry, and the second to the housewife. It was important that food and drink infections should not be dealt with as an isolated health education problem, but be linked up with all the other aspects of healthy living.

In some general discussion Dr. W. R. Martine (Birmingham) said that in his city 97% of the milk was pasteurized or otherwise heat-treated. Unfortunately, the remaining 3% was never entirely free from risk, and an outbreak of undulant fever had been attributed to this cause. Dr. J. B. W. Rowe (Harrow) said that the British Medical Association for the past four or five years had been hammering very hard at the Government to take up this question of pasteurization, but so far it had succeeded only to the extent that the Ministry of Food had appointed a departmental committee to look into the transport question.

Dr. Leonard Williams spoke of the state of the street markets in London and other towns. These markets were a means of bringing green vegetables to the public at a reasonable price, but he hoped that the distribution of vegetables might be so arranged that street markets could be abolished. It had been said that the medical inspection of food handlers in the United States had been dropped because it was impracticable, but he thought that only a very limited experiment had been made; it was tried out almost entirely on coloured people.

A Guildford councillor, Mrs. Croke, chairman of the Health Committee, described a recent effort made in her town, beginning with an exhibition visited by 7,000 people, following which an approach was made to the various food traders and organizations, resulting in the formation of a guild. Admission to the guild was obtained only by a promise to conform to a code of practice, which went rather further than the law required and insisted on the installation of washing facilities near sanitary conveniences and on the immediate notification to the medical officer of health of all cases of illness amongst the staff. The response had been encouraging.

An effort in Scotland was described whereby food handlers serving large holiday camps had been persuaded, with only a minimum of refusals, to submit to medical examination, including bacteriological examination of excreta, and a number of carriers had been found.

The proceedings closed with some remarks by Mr. H. Lesser, chairman of the Central Council, on the results which might follow so successful a national conference.

An early instance of the beneficial action of shock on mental disease, observed more than a century ago, is quoted by Dr. Claude Lillingston in *Blackwood's Magazine* for October in a biographical sketch of Philippe Pinel, the man who broke the chains of lunatics at the time of the French Revolution. Pinel was born on April 20, 1745, and in 1793 was put in charge of the Bicêtre, a cross between a prison and a hospital, where thieves and assassins lived with lunatics in chains. One of Pinel's patients, not an inmate of the Bicêtre, was a man of letters who imagined himself tired of life. Weighing with an alarming impartiality the various means of committing suicide the one against the other, he had not made his choice when he came to London. Late one night, having at last decided to drown himself, he went to a bridge over the Thames. About to jump into the river, he was attacked by footpads. Though practically destitute, he was furious at being robbed. He was also terribly frightened, and in sheer desperation he put up a gallant fight and escaped. His melancholy was so effectively dispersed by this incident that he forgot all about his intended plunge into the river, and he returned to Paris, where he lived happily enough. Pinel's notes on this case were found among his papers by one of his biographers, Dr. René Semelaigne, but, though Pinel would seem to have been aware of the occasional benefits of shock, he was in principle more in favour of soothing than stimulating his patients—witness his advocacy of tepid baths in preference to the total immersion in ice-cold water inflicted in his time till lunatics were almost frozen to death.

## SOCIAL MEDICINE AND HOSPITAL PRACTICE

An address on "Social Medicine and Hospital Practice" was given by Prof. J. A. RYLE at a meeting of the Medical Society of the L.C.C. Service, held at County Hall on Oct. 2. Dr. J. R. M. WHIGHAM was in the chair.

Prof. Ryle began with a remark on the neglect of the social background and foreground in hospital medicine. Patients were studied in isolation, remote from their natural surroundings. No complete picture was formed of the patient as a person, or of his illness as distinct from the label attached to it, or of its essential causes, economic or occupational. Pathological diagnosis might be precise, but personal and social diagnosis was defective. Despite the excellence of diagnostic techniques and specialized skills, hospitals were at a disadvantage compared with the experienced family doctor who had known his patient for a long time, had been inside his house, and was aware of his domestic situation, economic status, and the character of his work. A colleague in suburban practice had told him that instead of sending clinical letters with patients to hospital he now sent social letters, describing the patients' circumstances as he knew them.

Hospital medicine had become more and more exercised with clinico-pathological inquiry. Personal and social investigation had lagged a long way behind. The advent of the psychiatrist and psychiatric social worker had remedied the situation to some extent, but not entirely. The study of cases had suffered from an over-concern with pathology to the detriment of the total aetiology and prognosis—by total aetiology he meant much more than an assessment of specific factors, and included consideration of domestic, economic, occupational, educational, and psychological factors, all of which might buttress the specific cause or produce illness in the absence of specific cause.

An idea was current that what could be elicited from the patient himself was good enough. It was not good enough, partly because the patient was not always a good witness, and partly because the clinician was not always patient and skilful enough in interrogating him. Any case history should include not only heredity and occupation, and perhaps geographical and seasonal influences, but also the result of an inquiry into the immediate material environment both at home and at work. The occupation should be described in an intimate way, not merely named, and former occupations should be given if relevant. He was told by the medical officer of one factory that that factory alone there were six or seven varieties of welding, so that it was not sufficient to put a man down as a "welder." A colleague once wrote a paper on a case of "boiler-maker's g," only to discover that the patient had been a miner before he was a boiler-maker, and the South Wales mine had probably more to do with his disease than the boiler. Nutritional standards and habits were of obvious importance in assessment. The total social history might not always advance the diagnosis or improve the treatment, but it would rarely fail to contribute something to a better appreciation of the patient as a person, and sometimes it told them almost all they wanted to know, even when the laboratories and x-ray departments had failed them.

## The Patient as a Person

The information about the immediate material environment of the patient given at hospital often consisted of little more than his address; yet in some conditions, including almost any type of chronic disability, something ought to be known about the situation and type of his house, the room space in relation to the number of occupants, and, in the case of the housewife, the adequacy of her equipment and amenities and her hours of labour and freedom. A great deal might be learned from the personal relationships of patients, from such matters as wages, rent, cost of living, and number of dependants, and the effect upon the illness of a falling income, the fall being due to the illness itself. The proportion of income spent on food, and

the calorific value of the food, were also matters of importance. Educational standards should not be neglected, for they affected the patient's understanding of his own illness.

Hospital work, Prof. Ryle continued, was always biased by a concentration on objective methods and also by the fact that only the more serious forms and stages of disease were generally seen. Representative samples of disease were never seen in hospital, but only the worst samples. Hospital material was selected by gravity, by severity, or by interest or some other factor. Therefore judgments founded on hospital cases tended to be distorted. Clinical and social follow-up studies in most hospitals were inadequate. Hospital studies also were detached from healthy population.

The lecturer then proceeded to speak of the work of his own Department of Social Medicine at Oxford. There they were largely concerned with surveys of various types of population. It was a great corrective to clinical predispositions to be working among ostensibly healthy people. While hospitals would always be invaluable units within the total framework of medical and social services, they had disadvantages from their isolation. They were detached from the work of the general practitioner and from the personal and environmental services of the local authority, and also from the less serious aspects and varieties of disease and from healthy groups. Some hospitals had made efforts to compensate for these disadvantages. A good ward sister would fill in gaps in the information about patients as a result of her talks with the patients and their relatives, and now the extra help of the almoner and in some instances of the psychiatric social worker was available. The importance of occupational therapy and rehabilitation was recognized more and more. We were becoming more interested in the total patient, which included his social background. The follow-up departments in diabetes, pernicious anaemia, and cancer cases were further evidence that it was felt to be unsatisfactory to observe patients only for a limited time in a hospital bed. Follow-back methods should also be undertaken to get a better picture of how the illness arose.

## Importance of the Almoner

Under the new National Health Service he hoped that the almoner would be relieved of a great deal of her clerical work and would be concerned more and more with case work, organization of after-care, and follow-up studies. Her function would be social diagnosis and therapeutics in parallel with clinical diagnosis and therapeutics. In connexion with teaching hospitals and research she would have still other functions. What he had sometimes referred to as our modern endemic diseases—gastric and duodenal ulcer, chronic rheumatism, hypertension, psychoneurosis—often gave a sense of frustration in the hospital case because of their chronicity and their tendency to recur. The study of their total aetiology had as yet hardly begun. They were clearly due to continuing or recurring causes.

With the help of social pathology and rational human studies and socio-medical disciplines we should begin to balance anew the physical sciences and technologies which had ruled the roost in medicine during the last quarter of a century. The dividing walls between departments had to be breached. The almoner must more frequently be present at the ward round. The physician and house-physician must more frequently visit the almoner's department. The almoner's department and the registration department ought to be next door to each other. In numerous other ways associations of common interest could be brought about. Prof. Ryle confined himself to a single suggestion, that in every large hospital in the country, perhaps once a quarter or even once a month, there should be a conference, sometimes on a case, sometimes on a problem connected with the treatment of patients, and it should be attended by representatives of the clinical staff, the pathological and radiological staff, the almoner's department, the nursing staff, the dietitian, and the record officer. These were, after all, members of a large team. They lived side by side. They were, in fact, a social unit, and should be interested in one another's work, and none of them should feel a Cinderella.

Prof. Ryle's address was followed by papers by an almoner and a psychiatric social worker, and there was some general discussion.

## ANEURYSM AND LEUKAEMIA

A meeting of the Medical Society of the L.C.C. Service was held at St. Mary Islington Hospital on Sept. 3. Mr. I. I. PRICE demonstrated a case of popliteal aneurysm in a man of 42 who had had treatment by extraperitoneal lumbar sympathectomy, followed a week later by excision of the aneurysm. In discussing the treatment of this case, Mr. Price remarked on the value of preliminary sympathectomy in increasing collateral circulation. He had, after excising the aneurysm, cooled the limb by the use of an electric fan, but after a few hours found that the cooling was being overdone and that the foot was becoming cyanosed. The fan was therefore discarded, with a speedy improvement of the circulation in the leg.

Dr. A. L. JACOBS considered that there was little to gain from comparing the results of popliteal ligation after gunshot wounds with an operation of election such as Mr. Price had done. He said that he could not understand how cooling the limb could have any desired effect, for while undoubtedly metabolism was reduced by cooling so also was the circulation in the smaller vessels on which the collateral circulation depended. Mr. G. C. DORLING referred to a case of aneurysm of the femoral artery in which, after operation, the affected limb was not cooled but the other limbs were warmed up. The result had been good.

Mr. PRICE discussed a case of embolism in the brachial artery of a woman of 75 upon whom he had operated under brachial-plexus block analgesia. To remove the clot the artery had had to be opened in two places, but was repaired. There was never any danger of gangrene, but the radial pulse did not return for four weeks. He asked whether other members had had experience of brachial embolism, and what happened in cases where no operation was done. He considered that the ideal treatment was embolectomy and sympathectomy. Dr. A. L. JACOBS said that he had seen six cases of embolism in the brachial artery treated without surgery and without gangrene resulting, but he thought it probably best to give a dose of papaverine and observe the result. Arteriectomy was often the best operation in that it abolished the reflex spasm in the other arteries of the limb. Mr. G. C. DORLING pointed out that there was a danger of pneumothorax in the administration of the analgesic.

Mr. J. GARE said that he had always found the collateral circulation in the upper limb ample, and referred to a case in which he had tied the innominate, subclavian, and common carotid arteries without any gangrene resulting.

## Urethane for Leukaemia

Dr. T. ST. M. NORRIS demonstrated two cases of leukaemia treated with urethane. He had had them under observation for about 10 months, and, while pointing out that it was much too early to draw definite conclusions from the use of urethane, said that the results seemed to be as good as those obtained by deep x-ray therapy. The danger of agranulocytosis was always present, and it was very difficult to know when the maximum benefit had been received from urethane and to stop the use of the drug before agranulocytosis appeared.

Dr. B. GOTTLIEB said that urethane appeared to be quite useless in acute leukaemia; there might be a temporary improvement in subacute cases, but in chronic cases he had had an excellent response followed by relapse after the end of the treatment. A second course of treatment resulted in less marked improvement, and eventually the cases became resistant. However, urethane was at least as beneficial as deep x-ray treatment. He referred to a case of Hodgkin's disease in a girl of 16 who as a result of treatment with urethane now appeared perfectly well, and he suggested that it was well worth trying urethane in such cases.

Dr. G. STOR thought the risk of agranulocytosis was very real, one of the great difficulties being that it might start at any moment without warning. With regard to the use of deep x-ray treatment for myelocytic leukaemia, he had investigated the results in a series of cases, and on comparing them with a similar series untreated found that there was no lengthening of life.

## International Society of Surgery

TRÈS HONORÉ CONFRÈRE,

Le Comité Organisateur du XII<sup>e</sup> Congrès de la Société Internationale de Chirurgie qui s'est tenu à Londres du 14 au 20 septembre dernier comprenait les noms de la plupart des dirigeants des grands hôpitaux d'Angleterre, d'Ecosse, et d'Irlande. Ces confrères non seulement ont comblé les chirurgiens étrangers très nombreux à Londres de prévenances, mais leur ont encore ouvert largement leurs services hospitaliers pour leur permettre de se rendre compte des progrès considérables réalisés depuis la guerre dans l'installation de vos hôpitaux et dans les techniques chirurgicales.

Au nom des quelques 700 congressistes, nous vous prions de transmettre à tous les chirurgiens britanniques l'expression de toute notre reconnaissance.

Veuillez agréer, très Honoré Confrère, l'assurance de nos sentiments les plus distingués.

L. MAYER,  
Président.  
L. DEJARDIN,  
Secrétaire-Général.

## Acute Porphyrria

SIR,—We have read with particular interest the letter on this subject by Dr. Leo Rau (Sept. 13, p. 433), since many of his observations are of the greatest significance to our conceptions of the disease. The isolation of uroporphyrin from cases of any of the diseases cited by Dr. Rau—viz., meningitis, encephalitis, meningo-encephalitis, generalized herpes zoster, disseminated sclerosis, poliomyelitis, and subacute combined degeneration—is of such fundamental importance that we hope that Dr. Rau will publish his findings in greater detail as soon as possible. That coproporphyrinuria—i.e., an increase above the normal in the quantity of coproporphyrin isomers I and III excreted daily in the urine—may occur in a variety of pathological conditions including lead poisoning and hepatic diseases is well known. The appearance of uroporphyrin, however, is much rarer. In fact, indisputable evidence for the presence of uroporphyrin in the urine has only been forthcoming in the conditions of congenital porphyria (mainly isomer I, some isomer III) and acute porphyria (mainly isomer III). If Dr. Rau's claim can be substantiated, clearly our present viewpoint must be reconsidered. We very much hope that when Dr. Rau presents his findings in detail he will indicate whether the observed excretions were of type I or type III porphyrins.

We cannot, however, agree that porphyrin must be neurotoxic, since Klüber<sup>1</sup> has claimed that the normal central nervous system contains numerous microscopical granules which exhibit a red fluorescence in ultra-violet light and which possess some of the properties of porphyrins. The excretion of porphyrins in degenerative diseases of the central nervous system might equally well be the result of the degeneration rather than that the degeneration should be a result of the formation of porphyrins.

Lastly, we are surprised that Dr. Rau finds an excretion of uroporphyrin or an excessive excretion of coproporphyrin in the faeces in haemorrhage from the gut, as we should have expected any such excess of porphyrin to be limited to protoporphyrin and its near derivatives, mesoporphyrin and deuteroporphyrin.—We are, etc.,

C. RIMINGTON,  
CHARLES H. GRAY.

London.

## Sudden Death after Intravenous Injection

SIR,—I was interested by Dr. A. G. Oentlé's article (Oct. 4, p. 530), as I had a sudden death from this cause some years ago. The patient was a man of 83 who had auricular fibrillation and congestive heart failure. He was fully digitalized, and I gave him one dose of "salyrgan" intramuscularly, but it acted very slowly and the diuresis kept him awake all night. So two

days later I gave him a dose intravenously. Shortly after the needle had been withdrawn his breathing became stertorous, and he died very quickly.

Another patient to whom I gave a great many intravenous injections of salyrgan died suddenly on hearing an air raid warning. I mention this to show that there is an element of chance in these cases, and possibly the minute shock of the injection may be the real cause. At one time I thought that venipuncture might cause more shock than one ordinarily credits, and to test it I became a blood donor; but I never noticed the slightest effect myself.

Sudden death can occur from injections of a more simple kind. In 1942 I was called to see a man of 40 who had severe substernal pain of a few hours' duration, which I diagnosed as coronary thrombosis. I decided to give morphine and had to wait several minutes for some water to be boiled, during which I talked to the patient. I then gave him 1/3 gr. (22 mg.) of morphine subcutaneously, but "as I plucked my cursed steel away" his breathing became stertorous, and he died in a few minutes. There was not time for the drug to have acted, even if it had been given intravenously. Was it the slight shock of the injection added to the already desperate condition of the heart, or was death at that moment pure chance? It did not seem so to his wife, who was present all the time.—I am, etc.,

Norwich.

FREWEN MOOR.

### Poliomyelitis

SIR.—Mr. Chapman Pincher (Sept. 6, p. 396) states: "There is, however, one persistent source of fresh human stools, open to visitation by flies, embracing every town. I refer to our vast network of railway lines. Because of the primitive sanitation on our trains and the large number of apparently healthy people who may be poliomyelitis carriers, railway tracks may be an important source of the virus." One aspect of our investigation into the spread of poliomyelitis at the Hospital for Sick Children, Toronto, Canada, has been a study of the conditions that exist in the homes; and especially in homes remote from large centres. At the beginning of our field work this year we were getting cases from small isolated rural centres. In the field studies in these places our most isolated cases were in close proximity to railway tracks, often a very short distance, a matter of yards, from the railway tracks.

In a spot map the bulk of cases in the first group reported from the Province of Ontario were distributed along railway lines or along main routes of travel. One very suggestive study was in a farmhouse where there were seven people in the family. Two children developed poliomyelitis; one died with the bulbar type. None of the others in the family had been ill or had differed in their eating or visiting habits over the preceding month from the two children with poliomyelitis, except that within the incubation period of the disease the two children had eaten wild strawberries along the railway track, which easily could have been directly contaminated from the train or by flies.

This observation of the proximity to railways in our early rural series certainly makes us believe that such possible source of virus should be seriously considered and attempts made to confirm or disprove the possibility that this may be a very real source of dissemination of the poliomyelitis virus. Our observation may be possibly interpreted on the basis of chance, but in view of our experiences it would be interesting to know whether other medical men have made similar observations respecting the localization of cases in the vicinity of railway communications. We are fully appreciative of the limitations of the observations we have made, and our investigations are still in course of progress. But in view of Mr. Pincher's letter we thought it might be of interest to record these observations.—I am, etc.,

Toronto, Canada

NELLES SILVERTHORNE.

SIR.—Dr. John Mills's letter (Sept. 27, p. 507) on the use of "prostigmin" in cases of poliomyelitis suffering from paralytic ileus is a reminder that disturbances of the autonomic nervous system occur not infrequently in that disease.

It is well known that a high proportion of adult patients suffer from retention of urine, but the fact that the bladder can be made to empty by an intramuscular injection of 0.25 mg. of

carbachol seems to have been ignored. I have records of the cases in which catheterization was avoided by this means though in one it was necessary to administer the drug twice daily for four days before normal function returned. In fourth case with intercostal paralysis carbachol was tried, I doubtless owing to the simultaneous administration of atropin in an attempt to keep the respiratory tract dry, it failed.

I note that the only patient whose age Dr. Mills gives was a woman of 50. It would be interesting to know whether, as retention of urine, paralytic ileus is commoner in the higher groups.—I am, etc.,

Bristol.

D. S. SHORT

### Spasm in Poliomyelitis

SIR.—Is it possible that controversy on the existence of spasm in poliomyelitis may arise from differing conceptions of the meaning of the word? I have been able to follow a number of cases of the disease during the present epidemic from its early stages well into convalescence. I have not observed a true spasm in the sense that affected muscles have developed a pull without voluntary action on the part of the patient. I have, however, seen many muscles which had lost their extensibility from the earliest days of the disease, and these were tender and painful, particularly on attempted passive stretching.

Apart from the erector spinae those most often affected have been the biceps, hamstrings, and calf muscles, which are noticeably prone to develop contractions. They have usually been only partly paralysed from the outset, and have regained power well, though extensibility has only been recovered by the most careful physiotherapy. In one case in which this was hampered by seven weeks in a respirator shortening of the biceps remains after 4½ months, though their power is sufficient to flex the elbows against gravity and some resistance.—I am, etc.,

Luon, Beds.

H. B. LEE.

### Treatment of Varicose Veins

SIR.—My friend Mr. W. D. Park's reference to me (Oct. p. 547) is my excuse for attempting rather late to enter the discussion. He has perhaps too sparingly reported me and missed my point, which is that varicose veins, thrombosed apparently solidly and hard by sclerosants seldom fail to recanalized completely even after many months. I have removed by biopsy a short length of varicose vein, to sight and touch hard cord, ten months after sclerosant injection, and found only partly occluded by thrombus and with blood flow through it. The thrombus firmly adherent to one side of the vein would, presumably, have been digested in due time, and the varicosity become plainly "recurrent." If "injected" case with or without concurrent or subsequent ligation, had been followed up for periods over ten months, "injections," however little harmful, would long ago have been abandoned as useless. I submit that attention has been wrongly fixed on "thrombosis"—an incidental concomitant of the phlebitis and periphlebitis. In a series of biopsies I observed that recanalization always occurred unless the vein wall became necrosed, and with necrosis the injected vein was soft, not hard. The vein cannot be permanently occluded by firm hard clot undergoing a complete fibrosis, converting the vein into some sort of solid cord to be slowly absorbed. "Sclerosing" injection fails to obliterate the vein. These biopsies revealed that phlebitis and periphlebitis must be severe and extensive enough to destroy the vein's nutrient vessels. "Necrosing" injection will obliterate the vein, in the end without trace, by causing its death *in situ*. This necrosis in severity, extent, and possible harmfulness is not within the injector's control (while a scalpel is).

Many patients have varicose veins on both legs. This opportunity to try a different method (there have been more than one of fair surgical repute) on each leg in the same man, a perfect control, was seized. My cases at this hospital have been nearly all seamen, who were medically examined before signing on for each voyage, recurrences of varicose veins being sent back to hospital. My follow-up has therefore been adequate. Several years' observation made it clear that the least unsatisfactory method (none in my hands was 100% satisfactory) and the one with fewest recurrences, and of which the men made no complaints on score of pain, discomfort, loss of voyage and wages, was the rather slowly arrived-at method of multiple resections.

divisions-extractions, by which the whole varicose vein could be extirpated through incisions—rarely more than  $1/4$  to  $1/3$  in. (0.63–0.85 cm.) in length—at intervals along the vein, the sites for incision carefully selected in the standing patient and indelibly marked before operation. The incisions, made parallel to the lines of tension of the skin, gape but little and do not require suturing. Only very few ligations of severed veins are ever necessary, and perforating veins and tributaries can be divided and ligated or, if small, torn off flush with the deep fascia without the use of a vein enucleator.

In some cases new varicose veins have appeared so soon after extirpation of the old as to raise inescapably the question of overloading in the deep veins and a new compensatory reflux through deep communicating veins, and the wisdom of severing all deep communications, if that were feasible.

Here I take opportunity to record my indebtedness to Mr. Park's painstaking anatomical studies (*Lond. Hosp. Gaz.*, 1945, 48, 221). He has demonstrated the number, complexity, and variability of the communications, deep and superficial, of the veins of the leg, and thus provided illuminating and irrefutable anatomical warning—a timely reinforcement of the conclusions many of us had come to from clinical studies—that it is not feasible on any occasion to deal with more than a very few of the deep communications.—I am, etc.,

London, E.16.

H. M. HANSHELL.

SIR.—The article by Prof. A. M. Boyd and Mr. D. J. Robertson (Sept. 20, p. 452) with instructive phlebograms will I fear lead some to be less radical in their attacks upon varicose veins. It has always been accepted that solutions injected into varicose veins *must* inevitably enter the deep veins—and that very promptly, the patient noticing the taste of the solution within a few seconds of the injection. It has always been thought that the deep veins escaped damage because of the large volume of swift-flowing blood they contained diminishing internal damage, but most of all they were unaffected by sclerosing solutions because they were healthy normal veins.

I have encountered quite a number of Army pensioners with femoral thrombosis following ligatures and injections, but I have ascribed this complication to the long rest in bed (2–3 weeks) allowed after the operation of ligature or the occurrence of superficial thrombosis. Conditions in the Army apparently made it difficult to follow the ambulatory routine of civil life following ligatures and superficial thrombosis. I do not recall a single femoral thrombosis in a very large series of my own treated strictly on ambulatory lines. Others of the Army cases I have seen were due to operating on cases with bad thrombophilic histories, cases usually avoided for fear of stirring the hornets' nest.

Varicose veins are as hard to eradicate as rabbits, and if the article of Sept. 20 induces some to pull their punches I fear the pest of varicose veins will start to gain upon us again. For my part I will continue to inject downwards from the top ligature (if there is no valvular obstruction), upwards and downwards from the lower thigh ligature, downwards from the external saphenous ligature, and upwards from the excellent Dodds's ligature of the internal saphenous at the ankle. Up to a total of 100 ml. of 30% brine is used if the patient is anaesthetized, and less painful solutions if not. Following this all thrombosed veins are injected at weekly intervals. The foundation stone of success is to achieve a firm solid saphenous vein from groin to knee following the ligature.—I am, etc.,

London, W.1.

A. DICKSON WRIGHT.

### Leprosy and its Problems

SIR.—In the leading article (June 7, p. 813) and in Dr. Bernard Moiser's letter (Aug. 30, p. 347) mention has been made of cockroaches as possible carriers of lepra bacilli. The idea that insect vectors play a role in transmission of the disease is evidently sound. But if an insect is to blame it could not be the cockroach, at least not exclusively. In this country we have had leprosy for centuries, but the disease is now practically extinct. It could not have been transmitted by cockroaches, because they did not exist in this country until a decade or two ago and are still practically unknown in the countryside, where leprosy has had its origin.

If an insect is a vector of this disease, lice or fleas are more likely to be instruments of transmission than any others. Leprosy is a disease of filth and disappears with cleanliness. It flourished in the Dark Ages, when the human body was neglected and when the old maxim of St. Jerome was still valid, that "*poenitens eo foetidior, eo pulcherrior*." The common belief that leprosy is transmitted by sexual intercourse might find its explanation in a transfer of phthirus inguinalis. In this connexion it may be mentioned that McCoy and Clegg found acid-fast bacilli which seemed to belong to the leprosy family in lice. The fact that savages are exempt might be explained by their nakedness and consequent inability to breed the body louse. When the savage begins to wear clothes and live in houses he will contract the disease, if the opportunity for infection is there. All this could fit in with the louse as vector.—I am, etc.,

Reykjavik.

NIELS DUNGAL.

### Foetal Cries

SIR.—The prenatal cries of the Trowbridge foetus reported by Dr. E. Curphey (Sept. 27, p. 508) were anticipated by one at Strasbourg in 1821. A detailed account of the occurrence is given in a letter by Dr. William Lister to the *Edinburgh Medical and Surgical Journal* of October, 1822. There are remarkable points of similarity in the two cases.

The mother of the Strasbourg foetus had suffered repeated losses of liquor amnii up to the last month of her pregnancy. A sudden stumble, followed by considerable loss of liquor, occasioned unusually violent foetal movements and, to quote the author, "all at once the company present were alarmed by the cry of a child." The crying was repeated and "distinctly came from the womb of the patient. After a time it desisted." Two days later, in the eighth month of pregnancy, the mother went into labour and was delivered by cephalic presentation of a foetus of a premature infant. "The new born child," says the doctor, "gave a few weak tones" and died half an hour after birth. The author's comments on the aetiology of the event are worth repeating: "To judge from the evacuation of water, about the middle of the pregnancy, it may be well supposed that there had been some rent in the membranes by means of which the air was probably introduced. From the foregoing, it may then be well comprehended how the child cried; but how it could live 48 hours in the confined womb, surrounded with water in an amphibious manner is incomprehensible."

There may well have been other occasions between 1821 and 1947 when premature loss of amniotic fluid, air round the foetal face, and contraction of the uterus on the foetal chest have combined to produce cries loud enough to astonish the neighbours.—I am, etc.,

London, S.W.1.

W. HARTSTON.

### The Extent of Neurosis

SIR.—I cannot let Dr. D. Yellowlees's letter (Sept. 20, p. 468) pass without comment. After reading the leading article on "Neurosis in Industry" (Aug. 16, p. 257) I had originally considered the results of my small survey in the form of a short article, but I did not think it worth the space and condensed the material into a letter (Sept. 6, p. 396). I agree that "more emotionally ill than actually so" is not altogether a very apt phrase, but it is not easy to define shortly the difference between an illness due to the invasion of external elements, or failure of internal mechanism, and regarded with no undue alarm by the patient, and the exaggeration of discomfort energized principally by an increase in already present strong basic anxiety, probably acting through endocrine channels and along pathways of outlet grooved from early childhood. By "actual" I meant "in terms of physical pathology," rather than and as different from a state of psychical activity.

I am in complete agreement with the fifteenth paragraph of Dr. John Rickman's very apposite article (Sept. 6, p. 363), which formulates the situation of the bromide-receiving woman perfectly, and Dr. Yellowlees will notice that I rate her as 100% ill. By "normal ailment" I meant one which is understandable and treatable in physical terms of microbic invasion and chemotherapy, and which is the normal sphere of the physician. To

the psychoneurotic the physician can only be a "wet shoulder" and a generous giver of palliative sedatives, for the conduct of a psychotherapeutic analysis, involving many hours of a specialized relationship over many months and interacting problems, is beyond both the time and the scope of the general practitioner, even if the patient were willing to undergo it. I need hardly remind Dr. Yellowlegs of the degree of resistance of these anxiety-ridden people.

Whatever may be the genesis of "sufferings which lead to trivial or pointless complaints," to quote Dr. Rickman, they are kept in being by a dynamic vicious circling of anxiety which is rooted in disharmony of human relationships, both between the patient and his idealized image of himself and between him and his outer circle of relationships. The disharmony is in latent hostility and dependence and can grow like a weed as readily in a country cottage as in a town house. My own impression is that the disorders and evacuations of war, by adding what the German psychologists call *Angst der Kultur* to the inner anxiety, will produce a considerably increased crop of character disorders, if not actual neuroses, in the next 25 years. Society is already aware of it, in the widening provision of child guidance clinics.

If one has the time one will find disharmony and misery behind the demands for a nerve tonic, but nothing out of a bottle will help it to change. I would suggest to both Dr. H. G. St. M. Rees and Dr. Charles Shearer (Sept. 20, pp. 468 and 469) that the answer lies in the psychic walls built round an originally defenceless and unloved personality, which, while protective, prevent him from human community and participation; and let me add that they can be as strong as ferro-concrete and as crippling as osteo-arthritis.—I am, etc.,

Stockton-on-Tees.

L. F. DONNAN.

### Homosexual Offences and Psychotherapy

SIR,—Everyone must be grateful to Dr. F. H. Taylor for his most interesting paper on "Homosexual Offences and their relation to Psychotherapy" (Oct. 4, p. 525). There is a great shortage of facts regarding sexual abnormalities, and in the past on medical officers, who have valuable opportunities of studying severe and chronic cases, have published little. This, of course, not intended to minimize the very valuable contributions of Sir Norwood East.

One would naturally expect Dr. Taylor's views to be pessimistic, since in prison psychiatry the hopeless cases and failures are most likely to be met, while the successfully treated ones live normal lives. If I might be permitted to show the brighter side of psychotherapy I would cite a case of a Jewish woman aged 33 who was married, with two children. She suddenly found that she was falling in love with a pretty Irish maid and could not tear herself away from this girl. She wished to give her presents, dress her in different clothes, touch her, but not make any actual overt sexual approach. A few years previously she had fallen in love with another married woman. This patient was treated once weekly for three months. She lost her abnormal attachment, discovered she was able to feel real affection for her husband (whom she had liked but not really loved previously), and for the first time in her life had an orgasm. No doubt Dr. Taylor would say that this was not a genuine case of homosexuality, but one can always use this argument when insisting that "genuine" cases are not curable. I could produce other similar cases which have recovered under psychotherapy.

Dr. Taylor brings forward no evidence to dispute my contention that the so-called bisexuals are really partly developed homosexuals. Moreover, it is difficult to know where there is "a perversion in the psychiatric sense" and where there is "sheer depravity." Surely this depends on the outlook of the observer? I doubt whether the prostitute group is not composed of partly or wholly developed homosexuals also. Can anyone imagine that shortage of money would lead a normal man into homosexual prostitution? I can imagine many crimes from burglary down that most normal men would prefer. I would agree most whole-heartedly with Dr. Taylor's finding that the dreams accompanying nocturnal emissions are homosexual in inverts. In my experience they are almost entirely so, and why Hubert and East found otherwise is a mystery. I have always used the dream content to show the progress of a patient

under treatment, since it invariably changes as the patient recovers, and it is a bad sign if it does not do so.

It is obvious from Dr. Taylor's own statistics that punishment has no satisfactory effect, since so many cases have previous convictions. My own solution to this problem is that there should be a definite clinic for psychosexual conditions to which the courts send these cases for psychotherapy. The psychiatrists working on this one type of case would be certain to become more skilled than otherwise, and the patients more likely to be cured. Cases which did not respond and who were a menace to the community should be segregated under the best possible conditions, which surely could "differ appreciably from a prison sentence."—I am, etc.,

London, W.1.

CLIFFORD ALLEN.

### Treatment of Homosexuals

SIR,—Dr. F. H. Taylor's article (Oct. 4, p. 525) on homosexual offences makes me wonder once again why one never sees any mention of gonadal treatment in these cases; surely it must have some effect on at least a proportion.

A few years ago on transferring to a new area I came across a health visitor, aged about 35, who had a very deep voice and a distinct moustache. She had had a major operation, presumably a hysterectomy, about a year previously for dysmenorrhoea. About a year after I met her she was forced to leave the district as there had been several complaints from the mothers of girl guides in a company which she ran. I do not know exactly what these complaints were, but it was common local gossip that the girl was a homosexual. I feel sure that if this girl had been given appropriate hormone treatment at the time of and subsequently to her operation she would not have become a Lesbian.

I should be interested to know if others have any experience of these cases being prevented or alleviated by hormone therapy.—I am, etc.,

Rushden, near Buntingford, Herts.

L. M. M. BEADNELL.

### New Treatment of Rheumatoid Arthritis

SIR,—If, as Dr. G. L. Kerr Pringle (Oct. 4, p. 547) suggests, Dr. Imre Barsi's hypothetical anti-rheumatic substance (Aug. 16, p. 252) is a known hormone, it may be chorionic gonadotrophin or some other. If it is not chorionic gonadotrophin—and the remission of rheumatoid arthritis often begins so early in pregnancy as to suggest that it is not—then the anti-rheumatic substance, or more properly the balance of definite blood values of a number of hormones which has an anti-rheumatic effect, is likely to be present in the blood during the progestational phase of menstruation.

Although, as far as I am aware, no regular amelioration of symptoms between the 14th and 28th days of the menstrual cycle has been reported in rheumatoid arthritis, it seems reasonable to start the investigation of haemotherapy in this disease with trials of progestational blood, which is so much more easily obtainable than pregnancy blood. Dr. Barsi apparently did not make his injections at any particular phase of menstruation, nor does he mention any side-effects on the periods and the breasts, which one might expect. It would be interesting to know if there are any.—I am, etc.,

London, S.W.3.

JOHN EBBETTS.

### Supplementary Petrol

SIR,—Honesty is no longer the best policy. The medical profession have recently filled in their application forms for supplementary petrol and given an honest estimate of the total quantity of "motor fuel" required per month in their practices, but they have found in return that the Ministry of Fuel and Power has reduced all their allowances by 10%.

Surely, Sir, this is a case of class warfare at its worst. The bacilli, cocci, vibrios, and spirochaetes have not been asked to make a similar 10% reduction in their attacks on the community, and they will therefore gain an unfair advantage over the profession.—I am, etc.,

London, W.8.

H. STEPHEN PASMORE.

## POINTS FROM LETTERS

## Mind and Matter

Dr. E. V. PIERCY FOX (Keston, Kent) writes: In connexion with correspondence on the above subject may I quote Prof. A. N. Whitehead: "It seems that in bodies that are obviously living a coordination has been achieved that raises into prominence some functionings. . . . For lifeless matter these functionings thwart each other and average out so as to produce a negligible total effect." In this view the difference between the living and the lifeless is one of organization and not of ultimate nature. The mind-matter problem arose with the domination in thought of Cartesian dualism, mind and matter becoming irreconcilable substances.

## Medical Certificates

Dr. C. SPENCER WHITEHOUSE (Birmingham) writes: There is a practice which has become established during the last few years and which recently has expanded to such an extent as to constitute a major annoyance to all of us in general practice. I refer to the pernicious practice of requiring a medical certificate for practically any article that is in short supply. There is some reason in requiring a certificate from a doctor for some article which could reasonably be associated with the health of the patient and which a doctor might reasonably be expected to order—e.g., a vacuum flask. But when patients come and request a "note" for electric light, gas fires, edsteads, and above all an electric immersion heater, I think it is stretching the point too far. The latest request has been for a note to enable a patient (a young expectant mother) to purchase a baby's bath. It was not enough for her to produce her baby's ration book. . . .

## Milk Ration

Dr. C. J. PENNY (Winchester) writes: I venture to suggest that as time has now arrived when reconsideration should be given to the arrangements of the milk ration. In these last few weeks the general scarcity of milk has resulted in considerable hardship to many non-priority members of the public, and it is a matter of some difficulty for doctors to decide whether in borderline cases the priority certificate should be given when it is known that the general public's supply is thereby prejudiced. Since the commencement of the scheme the unit of priority has been one pint (568 ml.) of milk. I suggest that if the unit were reduced to half a pint the scheme could then be made far more flexible and fairer to all members of the community. If the half-pint unit were adopted, it would be possible under Group I to certify one to four units; under Group II, one to two units. Such an alteration would not greatly increase the doctor's work in respect of the individual certificate, though no doubt a greater total number of certificates would be issued. . . .

## Mortuaries for Dissection

Dr. O. P. CLARK (Worthing, Sussex) writes: May I suggest the simplest method of dealing with these cases is by communicating with the professor of anatomy at the university or college most likely to be interested. In my own case only a year or so ago I contacted King's College of London University, of which I am an ex-student, and was treated with the utmost courtesy and consideration. Now the necessary papers, including the appropriate form issued by the Home Office, are duly filed with my will, and whether my wishes could or might be flouted by any executor or other interested party I doubt very much, but this seems most unlikely. Incidentally, it is clearly stipulated that ordinary expenses are to be paid by the anatomy department and provision is made for religious observance and eventual burial in ground that has been suitably consecrated. . . .

## Control of Tuberculosis

Dr. SYDNEY GORDON TIPPETT (Horsham, Sussex) writes: The recent International Conference of Physicians has given the profession no fresh light on the real problem, which is how best to control tuberculosis. In the discussion on tuberculosis most of the speakers seemed with faint praise to damn the use of B.C.G., yet in the *Sunday Times* of Sept. 21 Lord Moran pleaded for the use of B.C.G. to protect those persons who were especially liable to become infected. From the report in the *Journal* (Sept. 20, p. 462) it seems that no mention was made of the problem—how to protect the recently infected person (child or adult) from developing tuberculosis at some later date. This was a tragic omission.

Let every effort be made to thoroughly try out any treatment that may be claimed will protect a human being from becoming infected, yet when that treatment has been found the way must still be found how to control tuberculosis. Koch nearly 50 years ago pleaded for the immediate treatment as soon as tuberculin showed the presence of tuberculosis. He was confident that such early cases, if treated, could have the disease arrested and in most cases would be cured. . . .

## Obituary

## W. ERNEST MILES, F.R.C.S.

A memorial service to Mr. Ernest Miles was held on Oct. 8 at Holy Trinity Church, Marylebone. The address at this service was given by Sir Gordon Gordon-Taylor, in the course of which he said:

. . . The name of Ernest Miles had been known to me by reason of his reputation as an operator and through his early writings from almost the beginning of the century, for he had already attained to the senior honorary staff of the Cancer Hospital, as that great institution was then designated, in the year when I first secured a medical qualification. About 1911 I became personally acquainted with him, when along with myself he was invited to become a member of the Surgical Club, one of the first, if not the very first, of those small coteries of men, meeting together for the promotion of surgical knowledge by informal conference and by travel. I still remember the thrill of belonging to a group which included surgeons like Wilfred Trotter, Percy Sargent, Sherren, Handley, and Ernest Miles himself.

On his maternal side Irish blood flowed in his veins, and some of his ancestors had served with Wellington in the Peninsular Wars. It was therefore not surprising that with this family military tradition, with so many personal attributes that make for leadership, with his passion for the horse and horsemanship, and his love of the copses and thickets and the greensward, he should have been a Territorial Officer in the years before the first Armageddon. I had the privilege of working alongside him for several months during the autumn of 1917 at an advanced abdominal centre just outside the walls of Ypres, where was collected together much of the "abdominal talent" of the British Expeditionary Force. It was an international group in very truth, for there were surgeons from the U.S.A., Canada, Australia, and New Zealand, as well as English, Scots, and Irish, and Miles was largely responsible for the wonderful friendship, the good fellowship and camaraderie that prevailed amidst that group, working "at the back of the front," on 16-hour "shifts" for months on end, in unpleasant, noisy, and sleepless surroundings, and he made of us a "brotherhood-in-arms."

He had a genius for friendship, and the deft fingers from which skill and pity flowed added adoring patients to the circle of his friends. He never said an unkind word of anyone, and if he could say nothing laudatory he kept his own counsel. In the words which Gibbon, the historian, used of Fox, it might be said of Ernest Miles: "Perhaps no man was ever more perfectly exempted from the taint of vanity, malevolence or falsehood." His philosophy of life might be briefly, yet imperfectly, expressed in the following lines:

From quiet home and first beginning  
Out to the undiscovered end  
There's nothing worth the wear of winning  
But laughter and the love of friends.

But for Miles there was something else worth winning—the conquest of disease and the relief of pain and suffering. It was the character and personality as well as the surgical achievement of men like himself and his colleague Charles Ryall that raised the prestige of the Royal Cancer Hospital and bequeathed to it a tradition to be maintained by their younger associates—by men like Jocelyn Swan, Percy Cole, Cecil Rowntree, and Cecil Joll. He was possessed of courage in abundance and a self-assurance and confidence which he could impart to others. . . .

Those who have been reckoned great in surgery must have been supremely skilled in the craftsmanship of our profession; they must by reason of the initiation of some novel and successful system of treatment have conferred untold blessing on mankind; their work must have illumined the dark, mysterious chasms in our knowledge of disease. It is necessary that they should have inspired their pupils and their surgical brethren with their own ideals, and should have inaugurated or sponsored some policy which has advanced the science and art of surgery. Ernest Miles fulfilled these criteria right well. . . .

This is not the time or place to discuss the details of his contributions to operative surgery; others more skilled than myself have already paid tribute to these in the medical press. In the words of Oliver Cromwell, "To be a Seeker is to be of the best Sect next to a Finder, and such a one will every faithful humble Seeker be at the end"; and Miles was happily spared to see the day when the methods which he had so long championed and employed during the dangerous pioneer period with unswerving conviction and dauntless courage became the recognized practice, now rendered safe by modern discoveries even in bands less deft and sure than his. . . . Academic honours came to him from many lands: from America, France, Greece. He was an international figure, and his work

influenced not only those of his own Britain but of lands beyond the seas.

Up there within the shrine on the old Castle Rock which looks out over the Scottish capital there is a corner dedicated to those of the Royal Scottish Fusiliers who perished in the first great war, and on the walls you may see inscribed those words which Thucydides, that consummate master of prose, puts in the mouth of the great Athenian, Pericles: "The whole earth is the tomb of great men. Nor is their name graven only in stone which covers their clay, but abideth everywhere without visible symbol, wrought in the stuff of other men's lives."

The tradition of Ernest Miles will live on not only in British surgery, but in the surgery of the world in the years that lie ahead. Let us thank God for the gift of Ernest Miles.

#### ERIK LYSHOLM

Prof. Erik Lysholm, the eminent Swedish radiologist, died in Stockholm on Sept. 26, aged 55. He had contributed much to diagnostic radiology, particularly on the neurological side. Educated at Uppsala University, he spent nearly all his professional life in Stockholm, the city of his birth.

The first radiological problem to which he applied himself was the accurate and thorough x-ray examination of the skull. Realizing that this could not be achieved with the standard apparatus, he set to work to design a skull table. Aided by his own considerable mechanical ability and by Georg Schonander, the engineer, he produced the first so-called "precision skull apparatus" in the late 'twenties. Since that time a number of improvements have been made, but fundamentally the apparatus has not altered and no other apparatus can compare with it for skull work.

Lysholm's greatest contribution to the physical side of radiology was the so-called fixed or Swedish grid. This simple device is placed in front of the x-ray cassette and greatly reduces scattered radiation, thereby improving the quality of the picture. There must be few x-ray departments in Europe or America without this grid, a certain tribute to its worth.

As a physician Lysholm will be remembered best for his original work on the accurate localization of brain tumours. It is nearly thirty years since air was first used in the ventricles of the brain for the localization of tumours, but it was left to Lysholm's genius to extract the maximum value from this method. In 1937 he published his famous monograph, "The Ventriculogram." It embodied the results of nearly 500 confirmed cases of brain tumour submitted to ventriculography. Lysholm clearly showed the various ventricular deformities produced by tumours growing from all parts of the brain. The method is so accurate that it is difficult to see how it can be improved, except perhaps in very small details. Latterly, his main scientific interests were in cine-radiology and the use of radio-active isotopes in radiology.

With the death of Lysholm the world loses not only one of its greatest radiologists but also a remarkable personality. Modest and shy by nature, all who knew him well deeply valued his warm heart. He had an unusual capacity for getting the very best out of his assistants and co-workers. He felt strongly that a team was necessary in such work as he was doing. This team was directed by his genius, but his modesty would not allow him to take more than a share of the credit.—J. W. D. B.

Dr. ANTHONY JOSEPH BORG died suddenly on July 7. Born in Sliema, Malta, in 1889, he graduated at Malta University in 1913. He joined the P. & O. Navigation Co., and was surgeon on the Egypt-Brindisi and London-Japan routes. In the 1914-18 war he served in the hospital ship *Sicilia* between Southampton and Boulogne and was in the first ship to return the "Old Contemptibles." Then he joined the Colonial Service and was posted to Fiji, serving as medical officer and at times as district commissioner for twenty-six years. After his retirement from the Service in 1942 he came to Auckland, New Zealand, where he practised as a physician. His cheerful personality endeared him to his patients and friends. His death robs the medical profession of a loyal colleague.—F. J. G.

GEORGE CECIL STRATHAIRN died suddenly at Nicosia, Cyprus, on Sept. 19. He was actively engaged in professional and social activities until two days before his death. Dr. Strathairn graduated at Edinburgh in 1901, and he took the certificate of the London School of Tropical Medicine and Hygiene in 1903 and the D.P.H. in 1912. He entered the Colonial Medical Service soon after qualifying, and served in various parts of

the world, including East Africa, Uganda, Fiji, Jamaica, and Cyprus. In 1929 he was appointed Director of Health, Cyprus, a post which he occupied until his retirement in 1933. His period of office was marked by great advances in the public health administration of the island. A sanitary inspectors' school was opened and attempts were made to improve village hygiene and sanitation through the medium of propaganda conducted by lectures, films, and personal contact with the villagers. After his retirement Dr. Strathairn decided to make a permanent home in Cyprus, for which country he had a great affection. In 1940 he rejoined the Service as a temporary district medical officer, and his experience proved of great value. Latterly he had concentrated on the organization of an aerodrome medical reception centre, and this work occupied more and more of his time. Dr. Strathairn, who had been a member of the British Medical Association since 1909, was honorary secretary and treasurer of the Jamaica Branch from 1926 to 1929 and represented the Branch at the Annual Representative Meeting at Manchester in 1929. From 1936 to 1938 and from 1942 to 1946 he was honorary secretary of the Cyprus Branch, and was its president in 1938-9.

H. M. S. writes: Strathairn's social activities were many. He was a very keen freemason, a prominent member of the local club, and for some time secretary of the racing club. His standard of personal conduct was very high, and it can be said with truth that he lived to serve others. His unselfishness, his generosity and kindness, his broad humanity, his wisdom and his humility associated with a charm of manner, stamped Strathairn as a great personality. He will live in our memories as a charming companion and a noble colleague.

Dr. HENRY GEORGE RAMSBOTTOM died at his home in Rochdale on Sept. 20 at the age of 63. His health had been poor for some years and he had had several periods of enforced inactivity. He struggled manfully against his disabilities and was in active practice until three weeks before his untimely death. He studied medicine at Edinburgh, and took the Scottish triple qualification in 1909. After acting as resident at Larbert and Perth Mental Hospitals he went to New Zealand to serve in the Mental Hospital Service at Christchurch. He returned to England in 1914, married, and entered general practice in Rochdale, where he spent the rest of his life, apart from service in the R.A.M.C. in 1916-17, when he was with the Ulster Division in France. Dr. Ramsbottom joined the British Medical Association in 1911. He took a keen interest in medical affairs and was seldom absent from B.M.A. and Panel Committee meetings. He was a member of the local medical war committee from its inception, and he was chairman of the Division in 1939-41. As recently as August the St. John Ambulance Association conferred on him the rank of Commander in recognition of over thirty years' devoted service. In charge of an A.R.P. post during the recent war, he was unsparing in time and trouble to ensure the efficiency of his unit. A Conservative in politics, he took an active part in local affairs. He was a member of the Rochdale Town Council from 1924 to 1930, but resigned when he became debarred under the 1930 Act because of his tenure of the appointments of public vaccinator and district medical officer. Outside his professional activities, "Rammy's" interests were mainly in sport. In his younger days he was a keen cricketer, and later took every opportunity in his leisure time to watch local and county cricket. He was also greatly interested in the Rugby League game and acted for many years as medical officer to the Rochdale Hornets. Until prevented by disability he was an enthusiastic, if only moderately proficient, golfer. He was by nature simple, direct, and kindly, and as a consequence it can truly be said that his friends were many and his enemies few, if any. He is survived by his widow and a married daughter, to whom we offer our sympathy.—L. K.

Dr. HELEN MARY DIXON, who died at a Bath hospital on Sept. 20 at the age of 69, was the only daughter of the late Mr. P. R. Dixon, of Manchester. After nursing experience in the first world war, and training as a midwife at the Rotunda Hospital, Dublin, she began the study of medicine later in life than is usual, and graduated at Bristol in 1925, when she was 46. For many years she did valuable part-time work as medical officer in charge of various infant welfare centres in Bristol and in Bath, and during the recent war she worked also in the school medical department at Bath, where she came to live about fourteen years ago. She was an excellent teacher and gave many courses of lectures for the Red Cross and other organizations. Mothers had great confidence in her judgment because they realized how deep was the personal interest she took in themselves and in their children. She had a forceful and attractive personality, and was much loved by her friends.

# MOIST HEAT

## IN

# RESPIRATORY CONDITIONS

The moist heat of an ANTIPHLOGISTINE pack is of definite value in relieving many of the troublesome symptoms accompanying affections of the respiratory tract. Cough—Muscular and Pleuritic Pain—Retro-ternal tightness—Soreness of the Chest.

ANTIPHLOGISTINE is a ready-to-use Medicated ointment—it maintains comforting moist heat for many hours.

A MAJOR IMPROVEMENT IN BABY SKIN CARE

Introducing *Johnson's*  
**BABY LOTION**  
ANTISEPTIC

leaves a  
discontinuous film . . .  
helps to reduce infant  
skin irritations

Johnson's Baby Lotion is a smooth, snow-white, antiseptic lotion, an oil-in-water emulsion, homogenised under pressure to permit extreme dispersion. It leaves a *discontinuous* film on the skin, enabling perspiration to escape and thereby helping to prevent irritation. This also materially reduces the incidence of heat rash. Johnson's Baby Lotion has been subjected to extensive laboratory and clinical tests and has proved itself a big step forward in baby skin care.

Makers of the famous Johnson's Baby Powder

The proteolysed extract of liver for  
parenteral use

## NEO-HEPATEX

A fractionated, enzyme-treated liver preparation for the treatment of pernicious anaemia by intramuscular injection.

**PROTEOLYSIS**—Original research in the Evans laboratories has shown that a better liberation of active principles from protein complexes, and an enhanced therapeutic potency can be obtained by the application of controlled proteolytic enzyme digestion to liver in the manufacture of anti-anaemia preparations.

**POTENCY**—Each batch is clinically tested before issue to ensure that a dose of 2.0 c.c. every fourteen days will restore the blood picture to normal in the average uncomplicated case of pernicious anaemia. A maintenance dose of 2.0 c.c. per month is usually adequate.

Other proteolysed liver preparations

d patients, who will alike miss her greatly. She held strong views about many social and medical problems, views which she put forward with characteristic good-natured vigour and tact. She was on the council of the National Gardens Club and was an active member of the Bath Soroptimist Club. J. F. B.

Dr. JAMES GEORGE COPLAND died in a Leeds nursing home on Sept. 21 at the age of 65. He was a student of Aberdeen University, graduating in 1906, and proceeding M.D. in 1920. Dr. Copland had been in practice in Huddersfield for thirty years. After a brief period as house-physician and house-surgeon to the ophthalmic department of the Aberdeen Royal Infirmary he went out to West Africa and served in South Africa for two years. In 1911 he went into general practice in partnership with Dr. James Raffan, of Huddersfield. Later he practised independently and succeeded the late Dr. John Wainman as borough police surgeon, a position he held for twenty-three years. During the 1914-18 war he served in the A.M.C. with the rank of captain. Dr. Copland was greatly interested in all types of sport, and particularly golf, curling, and football. He married Dr. Margaret C. Douglas in 1936. He will be greatly missed in Huddersfield, where for many years he had been one of the best known and most popular general practitioners.

Dr. HERBERT SHACKLETON died on Sept. 22 at the age of 84. Dr. Shackleton had been in practice for almost fifty years in Bradford, where he was one of the best known and most popular practitioners. He studied medicine at the University of Glasgow and at Leeds and qualified in 1885. He was in practice in Listerhills Road, Bradford, and had served on the Bradford City Council for nine years. Over the same period he was chairman of the Bradford Health Insurance Committee; he had been a member of the B.M.A. continuously for fifty years, and was chairman of the Bradford Division in 1922-3. For fifty-five years he had been a member of St. Mary Magdalene's Church, where a memorial service was held for him, and he had served for many years as a churchwarden. Advancing age had in no way diminished his grasp of affairs or his judgment. At the age of 80 he was elected chairman of the local insurance committee for the eighth successive year.

Dr. THOMAS FERGUSON died at Crieff on Sept. 23 at the age of 92. Dr. Ferguson graduated M.B., C.M. at Edinburgh in 1877. Three years later he settled in Dumfries, and there he remained in practice until his retirement in 1927.

Dr. WALTER WOODLEY STOCKER died suddenly on Sept. 28 at the age of 82. A student of St. Mary's Hospital, he took the Conjoint Diploma in 1889 and settled in general practice in Willesden after two years in Brondesbury. He was the last doctor in Willesden to possess a horse brougham. Dr. Stocker always took a great interest in local government. He was a member of the first Willesden District Council, and was chairman of the local fever hospital for six years. He was one of the first doctors to be attached to the Willesden General Hospital at its foundation. He had been district medical officer under the old Hendon Board of Guardians and then under the Willesden Board, retiring under the age limit in 1934. He had been a member of the B.M.A. for fifty-five years, and was chairman of the Willesden Division in 1924-5. Two years later he enjoyed reading his own obituary notices. He was said to have been the victim of an avalanche disaster in Switzerland. Dr. Stocker was popular as a general practitioner and as a public figure in Willesden, and he went into retirement in 1936.

Dr. ROBERT JOHN HELSBY, who died on Sept. 30 at the age of 62, was a native of Denbigh, and was educated at Denbigh National School and Denbigh County School. He took the Scottish triple qualification in 1910. He had been president of the Students' Society, and became demonstrator of anatomy for two years. He took over the practice of the late Dr. Richard Jones, of Bangor, whose daughter he married. During the 1914-18 war he served in the R.A.M.C., and was awarded the Military Cross and the French Croix de Guerre. He had been surgeon to the Caernarvonshire and Anglesey Infirmary, medical officer to the Post Office and Board of Education, and Admiralty surgeon. He was elected a member of the Caernarvonshire County Council in March, 1919, and became an alderman in 1940. Always keen on B.M.A. work, he had been president of the North Wales Branch in 1938-9, and had served on the local Insurance Committee from 1927, acting as chairman in 1932. He was elected a member of the Panel Committee in 1936, and had been chairman from 1939 to the time of his death.

Prof. Luigi Carozzi, formerly Chief of the Industrial Health Service of the International Labour Office, and now holding the chair of industrial medicine at Geneva University, writes: I have just learnt the sad news of the passing of my old friend Dr. J. C. BRIDGE, with whom I have been in close correspondence till quite recently. His death is a grievous loss, not only for his friends, but for all those medical men in Great Britain and in other countries who over many years have followed the work accomplished by him in the field of industrial medicine. The ranks of the "old guard" in this field are thinning out, and but too few of the younger men are ready to step into their places, which is a matter of grave concern.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

The Rockefeller Foundation has made a grant, available for one year, of \$2,500 for the University to purchase equipment in the United States of America for use in facilitating research under the direction of Prof. J. S. Mitchell, Ph.D., M.B., B.Chir., of the Department of Radiotherapeutics.

Titles of degrees were conferred by diploma on the following members of Girton and Newnham Colleges during August and September: J. M. Cockrell, M.B., B.Chir., M. Sutcliffe, M.B., J. Crossley, M.B., B.Chir., H. A. Jaques, M.B., B.Chir., Mrs. M. R. Simpson, M.B., B.Chir., S. G. Wills, M.B., B.Chir.

### UNIVERSITY OF DUBLIN

#### MOYNE INSTITUTE OF PREVENTIVE MEDICINE

As a memorial to the late Lord Moyne, who was assassinated in Egypt in 1944, his family have offered to bear the cost of building and equipping an institute, to be called "The Moyne Institute of Preventive Medicine," in Trinity College, Dublin. The Board of the College have gratefully accepted this munificent benefaction. The institute will provide urgently required accommodation for teaching and research in bacteriology and immunology and will also house the new Department of Social Medicine which the College authorities have decided to establish.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

Lectures in otolaryngology will be delivered at the College (Lincoln's Inn Fields, London, W.C.) on Nov. 3, 4, 5, 6, 7, 10, 11, 14, 17, 18, 19, and 21, at 6.15 p.m. The fee for the whole course is £5 5s.; Fellows and Members of the College and Licentiates in Dental Surgery will be admitted for £3 3s. Applications, accompanied by a cheque, should be sent to the secretary, Postgraduate Education Committee, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2.

A series of twenty practical demonstrations in anatomy will be given at the College (Lincoln's Inn Fields, London, W.C.) during the six weeks beginning on Nov. 3. The fee for the series is £7 7s., which includes access to the dissection room during the whole period. Applications for admission, together with a cheque for £7 7s., should be sent to the secretary, Postgraduate Education Committee, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2.

Research Scholarships will shortly be awarded by the College. There are two vacant Leverhulme Research Scholarships of the annual value of £400, with an allowance not exceeding £100 for expenses of research, tenable for one year in the first instance, but renewable at the discretion of the Council. The awards will be made either as scholarships or as grants-in-aid, according to the time available for research work. Scholars may be male or female, and must hold a medical qualification registrable in the United Kingdom or a university degree. Scholars must devote themselves to the investigation of some biological or clinical problem of disease as it occurs in man, with a view to the extension of surgical knowledge. Facilities for research will be available in the Bernhard Baron laboratories of the College in Lincoln's Inn Fields or at the Buckston Browne Farm, Downe, Kent. Applications, stating the nature of the proposed research and accompanied by a recommendation from a member of the staff of the applicant's medical school or university, should be sent to the secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2, before Oct. 27.

### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a special meeting of Council, held on Oct. 3, with the President, Mr. William Gilliatt, in the chair, the Honorary Fellowship of the College was conferred on Prof. J. M. Munro Kerr, Prof. C. G. Lowry, Sir Ewen J. Maclean, and Sir William Fletcher Shaw. A

report of the ceremony was published in the *Journal* of Oct. 11 (p. 583).

The following were formally admitted by the President to Fellowship:

G. S. Brown, G. A. Davies, G. P. FitzGerald, A. M. Johns, F. G. McGuinness, R. McRobert, R. C. Thomas.

The following were formally admitted to Membership:

H. B. Bagshaw, G. H. Baneroff-Livingston, Isabella R. Bishop, J. T. S. Brown, Gwendoline E. Cockrem, J. McD. Corston, G. A. Craig, K. J. R. Cuthbert, G. L. Daly, R. W. Danziger, B. C. Dastur, Josephine A. Davidson, N. E. C. de la Hunt, W. P. G. Dickson, I. Donald, I. A. Donaldson, Sara M. Field-Richards, T. B. FitzGerald, I. T. Fraser, A. M. Giles, A. McM. Graham, E. F. B. Hamilton, A. J. Hardy, Lois E. Hurter, D. W. James, D. H. Lees, M. Lipsitz, G. I. Louison, W. Love, C. J. MacKinlay, J. T. Mair, P. Malkani, Eileen C. Miller, W. G. Mills, P. R. Mitchell, J. D. Murdoch, Mary L. Neville, E. R. Ormerod, H. G. Page, Nancy Perry, E. E. Philipp, J. G. Pritchard, E. Rawlings, Elizabeth M. Rose, D. A. Fletcher Shaw, D. J. N. Smith, R. A. R. Taylor, J. Walker.

At the close of the ordinary meeting of Council on Oct. 4 Mr. Humphrey G. E. Arthure, M.D., F.R.C.S., assumed the office of honorary secretary.

## Medico-Legal

### ANOTHER CARBACHOL ACCIDENT

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

At a Stourbridge inquest held on July 17 a local practitioner gave evidence that a patient of his had died from an overdose of carbachol. The patient had been suffering from cancer; no bed was available in hospital, and a resident surgical officer advised an injection of carbachol. The doctor purchased three ampoules from the local chemist and, after reading the instructions, dissolved the contents of one ampoule and injected the solution into the patient's arm. The man immediately collapsed and died before an antidote could be given. When the doctor examined the other ampoules he realized that they were not the ones he had expected; each contained 0.1 g. whereas the proper dose was 0.25 mg. He said that when he had received them there had been nothing to indicate that they were not for injection. Evidence was given that the patient must in any event have died soon. The coroner remarked that if the doctor had spent a considerable time reading the instructions down to the last word, it would probably have occurred to him that the dose he was giving was 400 times too strong. The jury returned a verdict of accidental death and exonerated the doctor and the chemist, but considered it desirable that greater care should be taken with the instructions put up in individual packages of such drugs.

This is the fourth fatal accident that has resulted, since the introduction of carbachol into this country in 1941, from confusion between the two forms in which the drug has been marketed. One set of ampoules contains a therapeutic dose, the other contains crystals for use in ionization. In an action against the suppliers arising out of an accident at Oxford,<sup>1</sup> it was shown that the boxes of ampoules containing the crystals of "moryl" were sent out with a pamphlet similar to that put into the boxes of ampoules containing the therapeutic dose, stating that the correct dose was half to one ampoule but giving no warning that the crystals were not suitable for injection. Heavy damages were given against the suppliers, who stated that they had done and were doing everything possible to recall all boxes of crystals. It is to be hoped that the publicity given to this latest unhappy accident, together with the renewed efforts which the suppliers will doubtless make, will result in the recall of the remainder.

<sup>1</sup> *British Medical Journal*, 1946, 1, 1032 (and see also 1942, 2, 28, and 1945, 1, 62).

Though leprosy has for long been rare in Britain, cases among soldiers returning from the Far East have been reported (*Journal*, May 24, p. 731). A pamphlet entitled *The Homes of St. Giles for British Lepers* is therefore timely, and gives a brief account of these Homes from their voluntary foundation in 1914 to the present day. Nearly 60 patients, including 6 women, have been treated in the colony, which can at present accommodate 10 men and 3 women. Recreations of all kinds are arranged for the patients, and those who are able to do so are encouraged to work at gardening and keeping livestock for the colony.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 27

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

\* *Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.*

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis and Polio-encephalitis

There was a further decline in the notifications of poliomyelitis 02 (441) and of polio-encephalitis 27 (32) in England and Wales in the week ended Oct. 4. As was to be expected, the decline since the peak figure of 662 notifications of poliomyelitis in the week ended Sept. 6 has been much slower than was the case. It seems probable therefore that a fairly high incidence may persist for the rest of this year. If there is a relatively high winter incidence there may be opportunities for comparisons of the epidemiological behaviour of the disease in summer and in winter. The rise and fall of the notifications over the last eight weeks is shown in the table.

Week Ending	Notifications		Percentage Increase or Decrease on the Preceding Week (Poliomyelitis)
	Poliomyelitis	Polio-encephalitis	
Aug. 16 .. ..	646	45	+13.5
" 23 .. ..	626	50	- 3.1
" 30 .. ..	612	45	- 2.2
Sept. 6 .. ..	662	46	+ 8.1
" 13 .. ..	572	42	-13.5
" 20 .. ..	571	23	- 0.2
" 27 .. ..	442	32	-22.6
Oct. 4 .. ..	402	27	- 9.05

There were eight more notifications 38 (30) of poliomyelitis and two fewer cases 3 (5) of polio-encephalitis in London administrative county. The number of deaths ascribed to poliomyelitis and polio-encephalitis in the year 1947 has so far been 36 in London A.C. This compares favourably with the number of deaths due to whooping-cough 68, and to road traffic accidents 247.

Perhaps the most noteworthy decline in the notifications of poliomyelitis was in Yorkshire (West Riding) 18 (34).

Full details of notifications by age groups are not yet available for England and Wales; the cases notified up to the end of August were:

Age	Yorkshire (East and West Riding)	North-east Region	Northern Ireland	Scotland
Under 5	105 (47.5%)	182 (46.6%)	43 (31.5%)	168 (50.0%)
5-14 ..	66 (29.5%)	122 (31.3%)	52 (38.0%)	108 (32.2%)
15-24 ..	24 (10.5%)	50 (13.0%)	12 (8.6%)	26 (8.0%)
25+ ..	28 (12.5%)	36 (9.1%)	30 (21.9%)	33 (9.8%)

Comparison with earlier years shows that there has been an increase in the average age at onset. Mortality figures for England and Wales are not yet available, but the provisional figure for July suggests that the case mortality is about 10%.

## Cholera in Egypt

An official telegraphic report, dated Oct. 8, from the Egyptian Ministry of Health gives the following distribution of 366 confirmed cholera cases between Sept. 22 and Oct. 6:

Cairo .. ..	14	Dakahlia .. ..	11
Sharkia .. ..	135	Gharbia .. ..	3
Kaliubia .. ..	164	Giza .. ..	2
Alexandria (imported) ..	1	Suez .. ..	4
Menoufia .. ..	7	Ismailia .. ..	25

Cases have since been notified from Beheira and Girga and from Damietta and Port Said. The present epidemics in Egypt and in India are discussed in an annotation at p. 619 of this issue.

## Discussion of Table

In England and Wales further increases were reported in the incidence of scarlet fever 75 and measles 73, while a decrease was recorded for whooping-cough 273, acute poliomyelitis 130, dysentery 13, and paratyphoid 13.

The only variations in the local trends of scarlet fever were increases in London 26, Yorkshire West Riding 25, and Durham 25. For the second week a small increase in the notifications of measles has occurred; the only rise of any size during the week was in Lancashire 46.

The largest decreases in the incidence of whooping-cough were Lancashire 54, Warwickshire 39, and Middlesex 36. An increase of 9 in the incidence of diphtheria was notified in London. A further 18 cases of diphtheria were recorded in the outbreak in Birmingham C.B. The largest return of cases of dysentery was Lancashire 14.

In Scotland decreases were recorded in the notifications of acute poliomyelitis 38, diphtheria 13, and dysentery 7, while

an increase was reported for scarlet fever 39. The decrease in cases of poliomyelitis was general, while the fall in the incidence of diphtheria was mainly contributed by Glasgow.

In Eire an increased incidence was recorded for measles 33, scarlet fever 12, and diphtheria 13, with a decrease in the notifications of diarrhoea and enteritis 9. The small rise in the notifications of measles and diphtheria was fairly general, but the increase in cases of scarlet fever was confined to Dublin C.B.

In Northern Ireland only one case of poliomyelitis was notified compared with 10 in the preceding week. The notifications of scarlet fever declined by 12.

## Week Ending October 4

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,086, whooping-cough 1,086, diphtheria, 218, measles 1,256, acute pneumonia 330, cerebrospinal fever 46, acute poliomyelitis 402, acute polio-encephalitis 27, dysentery 97, paratyphoid 16, and typhoid 12.

## Medical News

## B.M.A. Library

The Association's Library is to be transferred from its present accommodation in the main building at B.M.A. House to the first and second floors of the Garden Court wing. To facilitate the removal the Library will be closed from 12.30 p.m. on Saturday, Nov. 1, until 9.30 a.m. on Monday, Nov. 17.

## Beckenham Hospital

At a meeting of the board of governors of Beckenham Hospital on Sept. 23 Dr. Richard Alfred O'Brien, C.B.E., was presented with an illuminated address and a cheque on his resignation of the post of honorary clinical pathologist and blood transfusion officer of the hospital. The address included an appreciation of Dr. O'Brien's "invaluable voluntary services over a period of eight years, during which time he has devoted himself wholeheartedly to the interests of the Hospital." Dr. O'Brien, who was elected a vice-president of the hospital in recognition of his exceptional services, has now left England for Australia. He was director of the Wellcome Physiological Research Laboratories from 1914 to 1939.

## Princess Ashraf Visits Hospitals

Princess Ashraf, twin sister of the Shah of Persia, arrived in London on Oct. 9 for a short visit under the auspices of the British Council. During her stay in this country she will study British nursing and nursing methods and see something of Britain's social services. The plan for her programme includes visits to some of the big London hospitals, a day nursery, a child welfare clinic, one of the Dr. Barnardo's Homes, and a tour arranged by the National Council of Social Services.

## Streptomycin in Scottish Hospitals

The Department of Health for Scotland has arranged for the treatment of selected cases of meningeal and military tuberculosis with streptomycin. Practitioners who have patients suitable for such treatment should apply through the medical officer of health. The following hospitals have been selected:

Aberdeen.—The City Hospital.

West Lothian.—Bangour Hospital.

Glasgow.—The Royal Hospital for Sick Children and the Knightswood Hospital.

Four local committees under the chairmanship of the deans of the university faculties of medicine will select patients suitable for treatment.

## Wills

Sir Almroth Edward Wright, who died on April 30, aged 85, left £47,904. Dr. Louis Cobbett, formerly lecturer in bacteriology at Cambridge University, left £52,687.

## COMING EVENTS

## Heberden Society

The annual general meeting of the Heberden Society will be held at 11, Chandos Street, Cavendish Square, London, W., to-day and to-morrow (Friday and Saturday, Oct. 17 and 18). At 4.30 p.m. on Oct. 17 there will be a business meeting at which officers, etc., will be elected; and at 4.45 p.m. a discussion on "Ankylosing Spondylitis" will be opened by Dr. C. W. Buckley, followed by Mr. N. L. Capener (Orthopaedics) and Dr. I. G. Williams (Radiotherapy). On Oct. 18, at 11 a.m., short communications will be presented. The annual dinner of the Society will be held at Kettner's Restaurant, Romilly Street, W., on Oct. 17, at 7.45 for 8 p.m.

**Kent Paediatric Society**

At the next general meeting of the Kent Paediatric Society, to be held at Maidstone County Hall to-morrow (Saturday, Oct. 18), at 3 p.m., Dr. J. Alison Glover will deliver the presidential address on "The Paediatric Approach to Tonsillectomy." Visitors will be welcome.

**Marie Curie Hospital**

The Duchess of Gloucester, President of the Marie Curie Hospital, will open the new nurses' home of the hospital at Hurdon House, 6, Fitzjohn's Avenue, Hampstead, N.W., on Wednesday, Oct. 22, at 3 p.m.

**Save the Children Fund**

The twenty-eighth annual meeting of the Save the Children Fund (20, Gordon Square, London, W.C.1) will be held at the Waldorf Hotel, Aldwych, London, W.C., on Wednesday, Oct. 22, at 3 p.m., when the speakers will be the Rt. Hon. George Tomlinson, M.P., Minister of Education, the Rt. Rev. Bernard O. F. Heywood, and Dr. Eleanor M. Singer.

**Society of Medical Officers of Health**

On Thursday, Oct. 23, at 6 p.m., at B.M.A. House (Tavistock Square, London, W.C.), Dr. Frederick Hall will be installed as president of the Society of Medical Officers of Health for 1947-8 by the retiring president (Sir Allen Daley) and will deliver his presidential address, entitled "The Economics of Public Health."

**Children's Moral Welfare Committee**

The annual meeting of the Children's Moral Welfare Committee (Rescue and Preventive) for Hampstead and St. Pancras will be held at Hampstead Town Hall on Friday, Oct. 24, with the business meeting at 5 p.m. and the general meeting at 5.15 p.m.

**Nutrition Society**

The Nutrition Society has arranged a whole-day conference on "British Needs and Resources of Calories, Protein and Calcium" to be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., on Saturday, Oct. 25, at 10.30 a.m.

**Veneral Diseases**

The Medical Society for the Study of Venereal Diseases will hold its General Meeting at 2.30 p.m. on Oct. 25 at 11, Chandos Street, Cavendish Square, London, W.1. Dr. C. S. Nicol will read a paper on "Gonorrhoea in the Female." The following lectures will be delivered on the dates shown: "Psychological Aspect of Venereal Disease," by Dr. Wittkower, on Nov. 29; "Neurosyphilis," by Dr. Purdon Martin, on Jan. 31, 1948; "Crime in Relation to Sex," by Dr. Holden, on Feb. 28; "Venereal Disease in Ophthalmology," by Mr. Lindsay Rea, on March 27; "History of Venereal Disease," by Mr. Johnstone-Abrahams, on April 24; Presidential Address on July 31.

**Medical Society of London**

The first half of the 1947-8 session of the Medical Society of London (11, Chandos Street, Cavendish Square, W.) opened on Oct. 13 with a pathological meeting. Other meetings have been arranged as follows: Monday, Oct. 27, 8.30 p.m., discussion on "Treatment of Peptic Ulcer" to be introduced by Dr. A. H. Douthwaite and Mr. Norman Tanner; Monday, Nov. 10, 8.30 p.m., discussion on "Cardiac Pain," to be introduced by Dr. William Evans; Monday, Nov. 24, 8.30 p.m., discussion on "Tumours of the Bladder," to be introduced by Messrs. E. W. Riehes, W. Somerville Mack, and Ronald W. Reid; Monday, Dec. 8, 8.30 p.m., discussion on "Teaching and Research in Social Medicine," to be introduced by Prof. J. A. Ryle. The Lettsomian Lectures on "Clinical Pathology in Relation to Medical Practice" will be delivered by Dr. Cuthbert E. Dukes on Mondays, Feb. 16 and 23 and March 15, 1948, at 9 p.m., and Dr. A. H. Douthwaite will deliver the Annual Oration on Monday, May 10.

**Cambridge Medical Graduates' Club**

It is hoped to revive the activities of the Cambridge Medical Graduates' Club with a sherry party at the Apothecaries' Hall (Black Friars Lane, Queen Victoria Street, London, E.C.) on Thursday, Oct. 30. As the secretaries of the club have been unable to trace a large number of old members, who have not received notices should communicate with Dr. R. A. Hickling, of 99, Harley Street, London, W.1. The subscription to this mainly social club is £1 ls. for life membership. There have been no new members since 1939. All Cambridge medical men are eligible for election, and those who have qualified since 1939 are urged to get in touch with their hospital representative or with Dr. Hickling.

**SOCIETIES AND LECTURES**

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields. W.C.—Wednesday, Oct. 22, 5 p.m. Arris and Gale Lecture. Mr. H. F. Lunn: A Contribution to the Anatomy of Inguinal Hernia; Friday, Oct. 24, 5 p.m., Arnott Demonstration. Mr. H. F. Lunn: The Pelvis and the Erect Posture.

**ROYAL SOCIETY OF MEDICINE**

Special Meeting of Fellows.—Tuesday, Oct. 21, 5.30 p.m., consider addition to By-law VI.1.

General Meeting of Fellows.—Tuesday, Oct. 21, 5.45 p.m. E for election to the Fellowship.

Section of Experimental Medicine.—Tuesday, Oct. 21, 5 p.m. Discussion: Renal Circulation. Openers: Dr. J. Trueta and K. J. Franklin.

Section of Pathology.—Tuesday, Oct. 21, 8.15 p.m. Presidential Address by Dr. A. B. Rosher: Some Observations on *H. influenzae* and its Pathogenicity.

Section of Endocrinology.—Wednesday, Oct. 22, 5 p.m. C meeting.

Section of Urology.—Thursday, Oct. 23, 8 p.m. Presidential Address by Mr. W. W. Galbraith: Modern Trends in Prostate Surgery.

Section of Paediatrics.—Friday, Oct. 24, 5 p.m. (Case 4.15 p.m.)

BRITISH INSTITUTE OF PHILOSOPHY.—At University Hall, 14, Gower Street, London, W.C., Friday, Oct. 24, 5.15 p.m. Dr. I. Popper: Moral and Political Aspects of Science.

EUGENICS SOCIETY.—At Royal Society's rooms, Burlington House, Piccadilly, London, W., Tuesday, Oct. 21, 5.30 p.m. Mr. Bramwell: Galton's "Hereditary Genius" and the Three Following Generations since 1869. All interested in the subject invited to attend the meeting.

LONDON: UNIVERSITY COLLEGE, Gower Street, W.C.—Tuesday, Oct. 21, 5.15 p.m. Dr. Bernard Katz: Some Properties of the Nerve and Muscle Fibres. Wednesday, Oct. 22, 5 p.m. Dr. M. H. Pirenne: Physiological Mechanisms of Vision.

NUTRITION SOCIETY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., Saturday, Oct. 25, 10.30 a.m. Conference on British Needs and Resources: Calories, Protein, and Calcium.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portico Place, W.—Wednesday, Oct. 22, 3.30 p.m. Mr. J. Lyle Carr: The Care of the Mother (Illustrated).

ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh.—Friday, Oct. 24, 8 p.m. Mr. G. M. Turner: Dissertation.

SOCIETY FOR THE STUDY OF ADDICTION.—At Medical Society of London, 11, Chandos Street, W., Tuesday, Oct. 21, 4 p.m. Dr. A. E. Carver: Alcoholism from the Psychosomatic Point of View.

**POSTGRADUATE DIARY**

EDINBURGH ROYAL INFIRMARY.—Thursday, Oct. 23, 4.30 p.m. Honyman Gillespie Lecture by Prof. John McMichael: Failure of Pulmonary Origin.

LONDON CHEST HOSPITAL, Victoria Park, E.—Friday, Oct. 24, 8 p.m. Dr. Bertram Jones: Some Types of Pneumonia.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tuesday, Oct. 21, 5 p.m. Dr. F. R. Bettley: Eczema.

The Fellowship of Medicine announces the following postgraduate courses: (1) Obstetrics and gynaecology, at Radcliffe Infirmary, Oxford, all day, Oct. 21 to Oct. 31. (2) Week-end course in rheumatism, at St. Stephen's Hospital, Futham Road, S.W., all day, Saturday and Sunday, Oct. 25 and 26. (3) Course in proctology, at St. Mark's Hospital, all day, Oct. 27 to Nov. 1. Full particulars can be obtained from the Fellowship of Medicine, 1, Wimpole Street, London, W.

Under the Oxford University postgraduate scheme a second refresher course for general practitioners will be held at the Royal Victoria and West Hants Hospital, Boscombe, from Oct. 20 to Nov. 1 inclusive. As before, local practitioners may attend some or all of the lectures and where the whole course is to be attended application should be made to the Dean, 41, St. Giles, Oxford. In the case of a few isolated lectures, however, practitioners will be made welcome; a syllabus will be provided upon application to the hospital. The first course, held in May last, was very well received and it is hoped that wherever possible practitioners will avail themselves of the opportunity to attend the new series of lectures.

**BIRTHS, MARRIAGES, AND DEATHS****BIRTHS**

HUTT.—On May 23, 1947, to Jill (née Chappell), B.M., B.Ch. (Oxon), the wife of Charles W. Hutt, M.B., B.Chir. (Comb.), Danedale Lodge, Minster Road, 1 of Sheppey, a daughter—Penelope.

REILLY.—On Oct. 2, 1947, in St. Mary's Hospital, W.2, to Joy (née Patrick), wife of Dr. M. C. T. Reilly, a son—David Tempest.

**DEATHS**

BRADBROOKE.—On Oct. 5, 1947, suddenly, at Horsham, Hugh Nash Bradbrooke, D.M., M.R.C.P., the beloved husband of Sylvia.

HARKER.—On Oct. 4, 1947, at the Southport Infirmary, Thomas Henry, M.I. L.R.C.P., M.R.C.S., of 75, Albert Road, Southport, treasured husband of Ethel Harker, and dear father of Margaret, Rosemary, and Ted.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Prolapsed Intervertebral Disk

**Q.**—What is the explanation for the intervals of quiescence in the symptoms due to a prolapsed intervertebral disk? Is there any evidence of a sloughing off of the prolapsed portion which might account for the cessation of symptoms? One author says that "a hole can usually be demonstrated which runs down into the depths of the intervertebral disk." What relation does this hole bear to the annulus? Does surgical removal of the pulp relieve the aching pain as distinct from the root pain?

**A.**—The most probable explanations for the quiescence of symptoms which so often occurs in cases of prolapsed intervertebral disk are: (1) that it is due to the prolapsed material returning within the disk substance; (2) that it results from the subsidence of the oedema which has been shown to be associated with a disk prolapse in the early stages. Probably both these factors play a part. At the present time, however, there are many who believe that the oedema factor may be the major one, and the beneficial effects of resting the spine, either in a plaster jacket or in recumbency, can perhaps best be explained on this basis. The "hole" referred to is through the annulus.

Removal of the prolapsed material, which is occasionally completely extruded and lying "free" outside the dura mater, results in complete cure of the sciatica and the backache in about 60% of all patients who fail to respond to conservative treatment. If there have been recurrences of sciatica over many years there are probably interstitial changes in the root, and complete freedom from discomfort cannot be guaranteed by operation. Furthermore, if the radiographs showed marked narrowing of an intervertebral space, and if there are arthritic changes in the facet articulations, removal of a prolapsed disk cannot be expected to cure the backache. These two factors—frequent attacks of sciatica over several years, and lumbo-sacral osteoarthritis—are mainly responsible for "failures" following removal of the disk alone. It seems highly probable that in these circumstances removal should be followed by lumbo-sacral fusion performed at the same sitting.

### Gold Therapy

**Q.**—(a) A woman aged 40 complains of pain at the base of the left index finger and right thumb. There are definite swelling and some tenderness at these sites. In March, 1946, x-ray examination was negative and her blood normal, but now skiagrams of her hands show multiple chronic arthritis of the rheumatoid type. Otherwise she is healthy. What injection treatment is indicated and in what dosage?

(b) A widow aged 60 complains of a persistent ache in the left cervical region below the ear. She has some limitation of lateral movement of the head, and x rays show osteoarthritic changes generally, and particularly in the atlanto-axial joints on the left side. Is she likely to be helped by any form of gold therapy?

**A.**—(a) There is little doubt that this is a case of early rheumatoid arthritis which should easily be arrested by adequate treatment. It is desirable that the erythrocyte sedimentation rate should be ascertained to confirm this diagnosis, and if it proves to be definitely accelerated gold treatment is indicated. This might be adopted by giving "myocrisin," the first dose to be 0.01 g., repeated in four days, then after a similar interval 0.02 g. for two doses, then 0.05 g., continuing this dose at weekly intervals for three or four months, and afterwards the same dose might be given once a month for a time as a maintenance dose. Careful watch must be kept for any sign of intolerance; the urine should be tested before each dose, a blood count done at least every three or four weeks, and any sign of skin irritation, digestive disturbance, or stomatitis will be an indication

for stopping administration for a time. Its resumption would depend on developments. With this line of treatment vitamin D should be combined, preferably in the form of cod-liver oil, and vitamin C has been regarded as prophylactic against any untoward results from gold.

(b) Gold would be of no service in this case. It appears probable that the pain is due to the osteoarthritic changes in the cervical spine. Radiant heat and gentle massage, or short-wave diathermy, would probably give relief, but the opinion of an orthopaedic surgeon should be sought if this proves ineffective. Manipulation in skilled hands might prove helpful, but should not be attempted otherwise.

### Re-employment of a Disabled Person

**Q.**—A lorry driver aged 57 who had a coronary thrombosis last December has made a good, though slow, recovery. It has been agreed that he should not go back to strenuous work. He has been with his firm for more than ten years, and used to drive long hours, day and night, through the war. They refuse to have him back and give him light work. Are they allowed to do this under the Disabled Persons Act and is he entitled to compensation?

**A.**—In the case quoted the employers are not bound by the Disabled Persons (Employment) Act, 1944, to take the workman back into their service, and he is not entitled to workmen's compensation unless (as seems unlikely on the facts stated) his illness is due to an accident at work. The workman is entitled to register under the Disabled Persons (Employment) Act, 1944, since his heart condition is a substantial handicap to his obtaining or retaining employment. He should go to the local employment exchange and ask to see the D.R.O. (Disablement Resettlement Officer), who will advise him as to his rights as a disabled person and assist him in finding suitable employment.

### Toxicity of Ergotamine and Ergometrine

**Q.**—I suffer from migraine and obtain relief from ergotamine tartrate and ergometrine. I find the latter more effective; 0.25 to 0.5 mg. is sufficient to abort most attacks. Can you give me information about the relative toxicity of ergotamine and ergometrine, their pharmacological action, and the safe limit of dosage?

**A.**—Ergotamine is much more toxic than ergometrine. It is an alkaloid which has produced gangrene of the extremities in a number of reported cases, and is one of the specific alkaloids of ergot responsible for gangrenous ergotism. Ergotamine causes spasm of the arteries and capillaries, as may be shown by the change in colour it produces in the cock's comb. It is impossible to state a safe limit of dosage, as this varies so widely in different persons. Some tolerate large amounts for long periods; others have shown symptoms after only a few milligrammes. Ergometrine, on the other hand, is almost free from toxic effects; it has very little action on the blood vessels, and so far no cases of gangrene have been described. The amounts required to deal with even frequent attacks of migraine should not expose any patient to risk.

### "Menstrual Tension"

**Q.**—A multipara aged 45, and menstruating regularly, suffers from hot flushes and some fluid retention in the tissues. Both symptoms have been controlled apparently by about 7 mg. of stilboestrol daily. She has been taking this only during the first fourteen days of the cycle, but complains of discomfort during the second half. Her general health is good and her periods are normal. Should this high dosage be reduced abruptly, or gradually? Is it true that vitamin E controls hot flushes?

**A.**—Stilboestrol 7 mg. daily is a massive dose for menopausal flushes; it is rarely, if ever, necessary to give more than 0.5 mg. once or twice daily, and less than this is usually enough. Now the patient is accustomed to taking large amounts it may be difficult to wean her from it. This should be done, however, by a process of gradual and systematic reduction of the dose during the course of two to three months. If she is menstruating regularly there is reason to doubt whether the flushes are

menopausal; they, as well as her other discomforts, may be part of a "menstrual tension state," of which retention of fluid in the tissues is always a feature. This condition is typically at its worst before and is least in evidence after a period, and the fact that the patient is better during the first half of the cycle does not necessarily mean that the stilboestrol is responsible. Indeed, it may be making the premenstrual discomfort worse, because oestrogens tend to cause fluid retention.

Probably no treatment at all is needed during the first half of the cycle, but during the second half the patient should keep to a sodium-free diet and restrict the intake of fluid to not more than 1 pint (568 ml.) in twenty-four hours. Ammonium chloride, 10 gr. (0.65 g.), in capsules might also be given to promote the excretion of sodium. This type of treatment often has a dramatic effect, but if the flushes continue it would be worth while trying vitamin E in large doses—say 20 mg. of a synthetic preparation twice daily. It appears to be beneficial in relieving menopausal flushes in some cases, but it is doubtful whether any more firm statement as to its value is justifiable on the evidence so far available.

### Haematospermia

**Q.**—*A man aged 45, otherwise apparently in perfect health, has for three months had a dark-brown coloration of the seminal fluid. What are the probable aetiology, prognosis, and treatment?*

**A.**—In many cases no cause can be found for a haematospermia. It is more likely to occur when there has been a mild vesiculitis, followed by a certain amount of congestion of the vesicle. Provided that any gross disease of the vesicles and prostate has been excluded the prognosis is excellent. No treatment beyond reduced sexual activity is needed.

### Living with a Gastro-jejunostomy

**Q.**—*What are the important rules of life after a gastro-jejunostomy for duodenal ulcer? Except for insomnia after late dinner I have been fit since undergoing the operation twenty years ago. I smoke and drink moderately but have incipient pyorrhoea. I remain consistently under weight. My appetite is not good, and excess food seems to pass through semi-digested.*

**A.**—The questioner is to be congratulated on his good fortune; if he has no more trouble than insomnia after late dinner he has solved the problem of living happily with a gastro-jejunostomy. If rules are to be formulated, they must be similar to those for patients with peptic ulcer: regular frequent bland meals, regular hours and habits, moderation in all things, and the assiduous cultivation of imperturbable and philosophic calm. In many instances gastro-jejunostomy has been done to relieve the patient of the need for observing these rules; but it is seldom wise to relax them until six months have passed without symptoms. Intestinal hurry is a common sequel, and hence he need for frequent small meals; nutrition is also better maintained in this way as absorption is more efficient.

### Sacralization of Lumbar Vertebrae

**Q.**—*Post-traumatic synostosis of vertebral transverse processes is not uncommon, particularly between the fifth lumbar vertebra and the sacrum. In such a case electrical treatment and massage have been advised, but this seems merely palliative. Is there any surgical treatment, or is this inadvisable owing to post-operative recurrence or adhesions?*

**A.**—It is true that the fifth lumbar transverse process is not uncommonly seen in radiographs to be enlarged, and this may be extensive enough to form an articulation with the sacrum or sometimes with the ilium. This abnormality is, however, congenital in origin and is known as sacralization of the fifth lumbar transverse process. It may be unilateral or bilateral. A true post-traumatic synostosis (fusion) between the transverse elements must be a rare occurrence. Trauma, however, may be superimposed upon a congenitally abnormal spine. As sacralization of the fifth transverse process is usually a symptomless

condition, discovered incidentally in the course of a routine examination of the spine, great care must be exercised before attributing a patient's symptoms to the bony abnormality. All other possibilities should first be excluded. Surgical removal of the bony mass is seldom indicated; and even in cases where has been thought that the symptoms were attributable to the abnormality—as, for example, when osteoarthritis is present at the false joint between the transverse process and the sacrum or ilium—operation has frequently been unsuccessful in relieving the disability.

Fractures of transverse processes are of importance only that they indicate extensive tearing of muscles and ligaments; the bony injury is insignificant, whereas the injury to the soft parts is severe. As in any severe injury, rest in bed for several days until the acute symptoms have settled, followed by the wearing of a plaster-of-Paris corset for three or four weeks, the correct initial treatment. Hyperextension exercises are started while the patient is still in plaster. They are continued when the plaster is removed, and mobilization of the injured portion of the back is assisted by physiotherapy. There has been a tendency in the past to regard this type of back injury as trivial. Unless it is treated efficiently, adhesions and chronically painful back are likely to result. From what has been said it should be clear that excision of a transverse process because it has failed to unite is rarely if ever indicated.

### NOTES AND COMMENTS

**Ringworm of Scalp.**—Col. W. H. CRICHTON, C.I.E., I.M.S. (ret.) writes from Faversham, Kent: With reference to the question answered regarding ringworm of the scalp (Sept. 13, p. 440) I have recently had occasion to deal with a widespread outbreak of the condition among school-children in North Devon. I found the treatment with a saturated solution of potassium permanganate followed by depilation by hand and application of Whitfield's ointment for a few days was both effective and practicable. The saturated solution of potassium permanganate is applied daily for fourteen days. In most of the cases, provided these were recognized and dealt with early, the fourteen-day course proved sufficient to effect a cure. In a small proportion of cases it was found necessary to repeat the course once, and in a few odd cases which have been neglected for some time it had to be repeated for a third time to achieve a negative laboratory result. Dr. E. A. J. Byrne was kind enough to make some phenyl mercuric chloride (0.2%) available for me, but the number of cases had by then declined and there was no opportunity for me to test this form of treatment fully. However, in one case in which I tried it the effect was magical. One application for a few hours was enough to effect a cure. There is one feature of this preparation which became apparent but for which I have no conclusive evidence—namely, that it seems apt to deteriorate on keeping. This was the only explanation for the failure of phenyl mercuric chloride in two cases which presented themselves for treatment after a considerable lapse of time following the undoubted successes in the earlier cases.

**"Happy Feet."**—Dr. DEAN A. SMITH (London, W.C.) writes: May I add a word to the answer on this subject (Sept. 20, p. 476). There is at least a probability that pantothenic acid is the B-complex factor whose deficiency is mainly responsible for the "burning-feet" syndrome (Gopalan, C., *Indian med. Gaz.*, 1946, 81, 22). A small number of patients whose symptoms have persisted for long periods since release from Japanese prison camps have been successfully treated with calcium pantothenate. This suggests that irreversible change occurs relatively late in this condition, and that either calcium pantothenate (20–40 mg. daily) or a good preparation of whole B-complex are worth trying in cases such as that of your correspondent.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 18 1947

## GENERAL PRACTICE COMMITTEE

A meeting of the General Practice Committee of the Association was held on Oct. 1. Dr. S. Wand was unanimously re-elected to the chair. The retirement of Dr. F. Gray from the committee was the occasion for a tribute to him from the chair and a warm vote of thanks for his long and conspicuous services. The subcommittees dealing respectively with colliery and works practice, Post Office medical officers, ship surgeons, and public medical services were reappointed.

### Petrol Restrictions

The question of petrol restrictions, on which a great deal of correspondence has been received at Head Office, was considered. An assurance was desired that doctors should not be subject to the requirement by officers of the Ministry to keep a log, which would be extremely irksome in their case, though they could, of course, not object to its enforcement in individual cases. It was agreed to watch the position and make representations if necessary.

Concerning the use of petrol for social meetings, the point was made that the doctor ought to be free to use his car, say, for a visit to the golf course if, while he was there, he would be on call to attend a patient. On the other hand, a doctor who went away for the week-end, leaving his practice to his partner or assistant, would obviously have no more right to claim the use of his car than an ordinary member of the public. It was agreed to make representations accordingly. During the war petrol was allowed for travel to meetings of war medical committees and other bodies, as well as, later on, meetings arranged in connexion with the proposed National Health Service. It was agreed to make representations to the effect that attendance at professional meetings was part and parcel of the doctor's professional work.

Some difference of opinion arose over the question of the "Doctor" sign on cars. The Representative Meeting wanted the sign discarded, but it was pointed out that with the appearance of new restrictions the value of some distinguishing mark had become more evident. A sign was said also to be of value when parking cars in central London. It was agreed, with two dissentients, that some sign or distinguishing mark was desirable, and by a small majority the word "Doctor" was favoured.

### Scales of Fees

A very large amount of detailed work came before the committee concerning rates of payment, much of it following upon previous negotiations. Questions were considered relating to the remuneration of Admiralty surgeons and agents, members of the Ministry of Pensions medical boards, Post Office medical officers, regional medical officers, ship surgeons, civilian medical practitioners in War Department and Air Ministry employment, and National Fire Service medical officers; and also to the fees for medical examinations for life insurance, for the examination of dependants of airmen, for medical attendance on members of the police forces, for examination of recruits to the Territorial Army, and for medical attendance on trainees at Government training centres.

On this last the Ministry of Labour had stated that it was prepared to introduce a scale of fees for medical attendance (including the supply of ordinary medicines) as follows: attendance at surgery, with medicine, 5s.; visit, with medicine, 7s. 6d.; visit, in urgent or dangerous cases, between 10 p.m. and 7 a.m., 15s., plus mileage in the case of visits. Discussion took place on the offer of 15s. for a night visit, and it was agreed to accept

this on condition that the hours were altered to correspond with those now accepted for night calls—namely, between 8 p.m. and 9 a.m.

### Miners' Contributory Schemes

A dispute which has arisen between the North of England Branch of the Association and officers of the National Union of Mineworkers concerning contributory schemes for medical attendance on dependants of miners came before the committee. The Branch has sought an increase in the payments under the scheme by 1s. 6d. a fortnight for each family for medical attendance, and also has indicated an intention to charge for medical certificates in order simply to discourage requests for multiple certificates, which make heavy demands upon doctors' time. The union representatives have taken exception to the increase in charges, and particularly to a charge for certificates, and there was some suggestion that the latter should be regarded as ground for an industrial dispute on which arbitration would be sought.

The committee agreed, after discussion, that a member of the Association's staff should visit the area and examine the position.

### Other Business

Various motions from the Representative Meeting had been referred to the committee and were dealt with by appropriate action. On the fees for medical certificates under the Lunacy and Mental Deficiency Acts the committee adopted the amendment moved by Derby at the A.R.M. that the fee should be at least 2 guineas whether the certificate was completed or not or whether the certificate was completed and the patient discharged by the justice.

A statement of the evidence for submission to the High Court and County Court Committees on procedure concerning fees for medical witnesses was approved.

## HEARD AT HEADQUARTERS

### Misleading Employment

A footnote to the recent request from the Ministry of National Insurance that practitioners should state on certificates the employment of the patient is afforded by a story told by Prof. J. A. Ryle recently at a meeting of the L.C.C. Medical Society. During the war in the Western Desert an Army officer found himself in a car which was being driven by a man obviously diffident and depressed about his driving. On being questioned he admitted that he did not like driving at all. Asked how he became an Army vehicle driver, he said that when asked what his civil employment was he had replied, "A fitter," whereupon they had instantly said, "Oh, mechanical transport," and sent him off to drive an Army vehicle. He added, "It is true I was a fitter, but in a ladies' costume department." Another example of the pitfalls which may lie in a brief statement of employment came from the same source. Someone at Oxford was interested in a series of five cases of duodenal ulcer, all in publicans, and began to think that there was possibly some connexion between the employment of a publican and the occurrence of this disease, until he learnt that four out of the five were not publicans when the trouble started, but had taken to such work because of their disability.

### Profligate Certification

Yet another certification requirement has been thrust upon the doctor—namely, to endorse applications for tobacco supple-

ments for old people. One member of the General Practice Committee the other day said that he had to vouch for the fact that an old lady of 75 was accustomed to smoke cigarettes. Not long ago the Minister of Health, in reply to a question, gave a portentous list of occasions on which medical certificates may have to be furnished by patients to Government departments. It runs to some 16 items. To begin with, there is the certificate of cause of death; the certificate in connexion with a claim to war pension or allowance; the certificate of mental disease or deficiency; the certificate under the National Insurance and Contributory Pensions Acts; the certificate supporting sickness absence when the Government is the employer; the certificate supporting an application for old age pensions at 50 in the case of blind persons. Then we have the certificates, which will soon become much more numerous, supporting a claim to leave or change employment. Again, under certain Wages Acts, a medical certificate may be necessary for employment at substandard wage rates. Then there are the certificates through which the possessor may obtain additional supplies of fuel or exemption from heating restrictions; the certificates for registration under the Disabled Persons (Employment) Act; certificates for obtaining surgical corsets; perhaps the most numerous class of all, certificates for supplementary rationed food for invalids and expectant mothers; certificates to support the claim for additional petrol allowances on medical grounds; certificates on grounds for exemption from military service; and, finally, certificates under the Cremation Act. Good luck to the Departmental Committee which is to consider the possibility of reducing the number of certificates and the improvement and simplification of their form and of the rules governing their issue.

#### The Robot Telephone

How far the robot telephone will catch on among doctors is still doubtful. A good deal of interest was shown when the device was explained at the Representative Meeting, and so far about 30 practitioners have put down their names as interested. A demonstration of the appliance was given at B.M.A. House the other day. The caller lifts the receiver and hears a stereotyped message to the effect that the telephone is unattended but that any message will be recorded and given to the doctor on his return. Then 45 seconds elapses for the caller to say who he is and what he wants. This time should be enough for any ordinary message, but one has to reckon with the garrulous caller, the ignorant and intimidated caller, and the caller who gives every detail except the name and address. It might be an improvement if, instead of the announcer-like voice of the stereotyped record, the doctor's own recorded voice were to reply to the caller. Apart from the robot telephone there are certain relay services being worked out, not specially for doctors, in which a number of direct lines are manned on a 24-hour basis and messages for subscribing members are taken down and relayed back when required.

## Correspondence

#### Working Hours in the N.H.S.

SIR.—Hitherto paying patients have consulted the doctor when they had reasonable grounds for doing so—often after a preliminary period of self-diagnosis and self-medication. Pauper patients have been less reticent about their illnesses, real or imagined, and have sought the benefit of his advice for minor conditions that once would have been disregarded. When the whole nation is entitled to medical treatment—for which they will have to pay, although they don't yet realize it—it is not difficult to visualize how every adolescent ("manhood: how lost and how regained"), bridegroom-to-be, father, mother, and all the little Willicies, Patricias, and Pamelas ("I haven't seen anything for two months, doctor") will joyfully flock to his surgery in their thousands. Normal work will be enormously increased.

A well-known member of Parliament who has paid very close attention to the Bill and the Act assured me that to operate the National Health Service fully will require a *further hundred thousand doctors*. I could scarcely credit this until I heard a further estimate of a hundred and fifty thousand. I was told

that the plan was to mass-produce these by free medical education and take them straight from the production line and turn them loose on the public. This is not a very cheering outlook for those who expect shorter working hours in the near future with a mere 70,000 on the Register.

Nobody is more conscious than I of Mr. Bevan's tender solicitude for our profession, but many of us feel we would like more information on these matters from those who are in position to give it reliably.—I am, etc.,

Brookwood, Surrey.

H. M. STANLEY TURNER.

#### National Health Service

SIR.—Many of us feel that it is time that the iron curtain hiding the activities of the Negotiating Committee should now be raised. Less than nine months remain before the Act comes into force. Already doctors are being approached in connexion with regional and other boards designed to further the working of the Act, and as yet we have no information on which to base any decision to serve or not to serve. Both hospital staffs and general practitioners are in the dark as to their future. The time is extremely short for the various regional meetings and for the co-ordination of opinion on our attitude towards any new provisions or compromises.

Is it true that the Minister of Health has not yet himself met the various sectional committees, or is the Negotiating Committee still dealing with permanent secretaries? We are in danger of once again sinking into the apathy which has so often prejudiced our interests in the past. It is essential that we should know at once how far the negotiations have succeeded in emphasizing our refusal to work the Act as it stands and whether we must prepare to fight for the traditions for which we stand.—I am, etc.,

Cambridge.

A. E. MOORE.

#### Working Day in the Services

SIR.—May I most heartily support "F.O." (*Supplement* Sept. 13, p. 66) in what he has to say on the subject of medical officers in the R.A.F.? I too have never done a day's work since entering the Service, nor have I met a medical officer who has, although I have been in uniform nearly twice as long as "F.O." I cannot, however, help feeling that on the whole I have been fortunate in having been more occupied than many of us, in spite of his low work record, such is the farcical position obtaining to-day.

Throughout the main part of my time I have been the junior on a station and have found, as did "F.O.," that two hours a day sufficed to finish my work, except when my senior has been on leave; sometimes then I have been occupied all morning. However, for one period of six months I had a station of my own. I took over from a civilian doctor, who told me that he did my work in half an hour a day. How true this was. Over one calendar month the entries in my sick-book averaged 1.2 per day, and this included follow-up visits. Over the whole six months I doubt if I averaged three entries per day. I was simply being used as a caretaker for a few medical stores. Nevertheless, I had to remain there till the station closed down.

This enforced idleness is, in my opinion, resulting in the young doctors' losing, through lack of practice, most of their professional skill and ability and, what is far worse, their inclination to do a hard day's work such as they accepted as the normal life of a house officer before their call-up. Can nothing be done by the B.M.A. or Central Medical War Committee to stop this waste of talent? The Government talk of drones. Right! Give us the chance and we will work. It is not our wish to be a burden on the Exchequer.—I am, etc.,

F./LIT.

#### Suspension of Basic Petrol

SIR.—Since the announcement in the House of Commons on Aug. 6 by the Prime Minister that a reduction in the levels of petrol rations would have to be made, I have felt a sympathetic attitude to the many people who live in the country and who have been using their basic petrol for many necessary obligations easily exceeding the journeys they did for pleasure. In fact not a few who are my patients have spoken to me of their predicament, and invariably each one said, "Of course, you will be all right"; and I glibly imagined so also.

However, the other day I received my allowance for the next x months and noted that they had cut my ration by 20%. My note stated: "As from Oct. 1 all supplementary petrol allowances will be reduced by 10%. In common with all other categories of private car users a reduction will be made in allowances to the medical profession." They add that it is hoped that I will be able to achieve this saving in my petrol consumption, etc., etc., and that if I find it not possible to continue to the end of the period on the reduced allowance they will be prepared to consider such assistance as may be necessary. Since I was fair in my previous application I will be forced to make this application probably after five months have elapsed, as the cut amounts to one month's travelling.

Surely we (75,000 of us) in Great Britain must realize that the time has come when such a body of professional men and women will no longer tolerate being dictated to in such a manner. We are fast losing our freedom, and if no effort is made now, then God help us, our patients, and our country.—am, etc.,

Whitley, Lancs.

CHARLES E. BROWN.

### Telephone Calls

SIR.—Before the war the Post Office consented to accept the service of referring calls for medical men at a nominal charge of £1 per quarter. This was an extremely useful service for us in those days. With the present shortage of staff, etc., this service is doubly more important and essential. Unfortunately, the Post Office refuse to accept any new subscribers, the reason being that they have got no "equipment," whatever that may mean. Whereas I am not able to say whether this equipment is very elaborate and expensive, it strikes me that in view of the necessity for us to secure a continuous and uninterrupted telephone service the Post Office might well be induced to acquire his equipment. At present all the Post Office will do is to put me on the waiting list, on which I am number 20, and I am informed by them that the only chance of getting this service is to wait for the 19 doctors prior to myself on the list to die. Can anything be done in this matter?—I am, etc.,

London, W.1.

ARTHUR MILLER.

## H.M. Forces Appointments

### ROYAL NAVY

Temporary Surgeon Lieutenant W. Stephen, R.N.V.R., has been transferred to the Royal Navy.

Temporary Acting Surgeon Lieutenant R. H. Cowling, R.N.V.R., has been transferred to the Royal Navy in the rank of Surgeon Lieutenant.

Acting Surgeon Lieutenant T. S. Law to be Surgeon Lieutenant.

### ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Captain H. O. Martin, V.R.D., has been placed on the Retired List.

Surgeon Commander St. G. B. D. Gray, V.R.D., has been placed on the Retired List.

Temporary Surgeon Lieutenant-Commander R. H. Roberts has been transferred to List I of the permanent R.N.V.R.

Temporary Surgeon Lieutenant-Commanders J. M. Teasdale and M. G. Low have been transferred to List II of the permanent R.N.V.R.

Temporary Acting Surgeon Lieutenant-Commanders R. C. Ponder and C. H. F. Wood have been transferred to List I of the permanent R.N.V.R., in the rank of Surgeon Lieutenant-Commander.

A. G. W. Hill to be Surgeon Lieutenant-Commander.  
Temporary Acting Surgeon Lieutenant-Commanders W. M. Wilson, E. R. Van Langenberg, L. Willoughby, T. O. Mason, G. E. Loxton, W. M. Scott, L. V. Gimson, A. M. McCall, J. G. Byrne, J. G. Taylor, and H. J. Harris have been transferred to List II of the permanent R.N.V.R., in the rank of Surgeon Lieutenant-Commander.

Temporary Acting Surgeon Lieutenant-Commander J. E. Morton has been transferred to List I of the permanent R.N.V.R., in the rank of Surgeon Lieutenant.

Temporary Acting Surgeon Lieutenant-Commander M. M. Walker has been transferred to List II of the permanent R.N.V.R., in the rank of Surgeon Lieutenant.

Temporary Surgeon Lieutenant D. K. T. Wallace, M.B.E., has been transferred to List I of the permanent R.N.V.R., in the rank of Surgeon Lieutenant-Commander.

Temporary Surgeon Lieutenant J. F. Ramsden has been transferred to List II of the permanent R.N.V.R., in the rank of Surgeon Lieutenant-Commander.

Temporary Surgeon Lieutenants J. J. Ennitt, H. R. Gray, W. P. Small, R. K. Reid, J. W. Maybury, A. C. MacDonald, J. Alexander,

J. E. Russell, J. G. H. James, J. R. K. Preedy, J. R. Briggs, R. B. Slater, W. M. Lancaster, P. G. Arblaster, C. G. Attenborough, C. Fleming, and J. C. E. Preshall have been transferred to List I of the permanent R.N.V.R.

Temporary Surgeon Lieutenants J. MacDonald, J. G. Craddock, G. M. Forsyth, J. K. Black, E. J. King, A. W. Hagger, J. R. Ivey, A. J. Fairrie, G. A. Smith, J. C. Brass, V. O. B. Gartside, P. G. Dalgleish, R. S. Parkin, P. Pattison, A. B. Maclean, A. M. Robertson, F. R. St. C. Assinder, G. J. F. Briggs, D. Kennedy, B. M. Laurance, F. K. Muir, J. D. Stride, D. H. M. Titcombe, G. L. T. M. Patey, M. L. Graeme, and L. M. Rose have been transferred to List II of the permanent R.N.V.R.

### ARMY

Colonel W. K. Morrison, D.S.O., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Brigadier.

Major T. R. J. P. Kerwick, half pay list, late R.A.M.C., has retired on account of disability.

### ROYAL ARMY MEDICAL CORPS

The notification regarding Major (War Substantive Lieutenant-Colonel) J. P. Douglas, O.B.E., in a *Supplement to the London Gazette* dated Aug. 26, has been cancelled.

Lieutenant-Colonel L. B. Clarke has retired on retired pay.

War Substantive Majors G. W. Reid, R. K. Pilcher, M.C., J. M. Matheson, R. Paul, G. L. Ritchie, J. N. Hamill, and B. W. Hughes to be Majors.

Captains H. Pozner, M.C., H. R. Miller, S. Boan, W. M. Owen, and J. W. Spence to be Majors.

*Short Service Commission, Specialist.*—War Substantive Major E. F. Edson has retired and has been granted the honorary rank of Lieutenant-Colonel.

*Short Service Commissions.*—Captains J. P. Scrivener, M.B.E., and H. D. G. Hetherington have been appointed to permanent commissions. Lieutenants J. Prentice, R. M. Lang, J. M. Adam, R. H. F. James, R. W. Campbell, and D. C. V. Stewart to be Captains.

Captain H. J. Elverson, from Short Service Commission, has been appointed to a permanent commission.

### LAND FORCES: EMERGENCY COMMISSIONS

#### ROYAL ARMY MEDICAL CORPS

War Substantive Major L. C. Allan has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

War Substantive Major G. E. Ord, O.B.E., has relinquished his commission on account of disability and has been granted the honorary rank of Lieutenant-Colonel.

*Short Service Commission, Specialist.*—War Substantive Majors C. R. St. Johnston and R. R. Henderson have relinquished their commissions and have been granted the honorary rank of Lieutenant-Colonel.

War Substantive Captains J. A. Rich, J. L. Penistan, J. Goldstein, M. Goldberg, A. J. Heriot, R. Saffley, and L. J. Wolfson have relinquished their commissions and have been granted the honorary rank of Major.

*Short Service Commission, Specialist.*—War Substantive Captain M. A. Goodwin has relinquished his commission and has been granted the honorary rank of Captain.

War Substantive Captain R. E. Irvine has relinquished his commission on account of disability and has been granted the honorary rank of Captain.

War Substantive Captain L. Tajkef has relinquished his commission and has been granted the honorary rank of Major. (Substituted for the notification in a *Supplement to the London Gazette* dated June 11, 1946.)

To be Lieutenants: R. Armatage, D. F. Barrowcliffe, J. C. Batten, N. H. Birch, A. Blench, D. G. Breeze, J. Butler, W. J. H. Butterfield, H. Caplan, G. M. Colson, J. Cox, P. E. A. De Caestecker, J. J. Duffy, S. Eden, H. B. Farrell, R. H. Freeman, G. Fyfe, D. W. S. Gordon, R. J. Howat, G. Hughes, C. W. L. Jones, J. G. Kendall, J. R. Leslie, H. S. Levy, G. H. Luffingham, J. D. Lunsden, M. C. Macleod, W. C. Macpherson, D. McL. Maxwell, J. R. May, R. J. Mitchell, S. Moller, J. Moss, C. MacL. Ogilvie, W. H. Oldershaw, B. W. Orchard, G. S. Plant, A. G. Pollen, J. G. P. Power, J. P. Pracy, F. L. Rawson, F. W. Richards, J. C. Rogers, C. G. Sim, R. J. H. Smith, T. B. Stirling, G. W. Storey, M. K. Towers, L. Walkden, G. T. Watts, F. E. Webb, N. Weiner, P. R. J. Williams, J. T. H. Wise, P. Wise.

### WOMEN'S FORCES

#### EMPLOYED WITH THE R.A.M.C.

War Substantive Captain L. Cooke has relinquished her commission on account of disability and has been granted the honorary rank of Captain.

To be Lieutenants: Margaret R. Biggs and Margaret J. McNabb.

### ROYAL AIR FORCE

Air Commodores (Acting Air Vice-Marshals) F. J. Murphys, C.B.E., K.H.S., and T. McClurkin, K.H.P., to be Air Vice-Marshals.

Group Captains (Acting Air Commodores) A. Briscoe, C. T. O'Neill, O.B.E., and W. J. G. Walker, C.B.E., to be Air Commodores.

Wing Commanders A. Harvey, J. D'I. Rear, J. Hutchieson, J. Hill, G. E. Church, J. C. Neely, G. W. McAleer, F. E. Lipscomb, C. W. Coffey, O.B.E., and L. Freeman to be Group Captains.

Wing Commander T. J. D. Atteridge has reverted to the Retired List.

Squadron-Leaders E. A. Rice, G. H. Stuart, D. J. Sheehan, A. S. Amsden, H. D. Conway, J. R. R. Jenkins, P. A. Lee, J. R. Cellars, A.F.C., D. F. S. Shaw, D. J. Dawson, J. H. Neal, R. H. Pratt, C. C. Barker, A.F.C., J. C. Taylor, W. T. Buckle, E. S. Sidey, J. C. Bowe, C. E. G. Wickham, and A. Muir to be Wing Commanders.

Flight-Lieutenants J. Park, W. K. Stewart, A.F.C., F. D. Campbell, and D. C. Light to be War Substantive Squadron-Leaders.

To be Flight-Lieutenants: S. M. Rigg, R. J. A. Morris, T. A. Evershed, A. L. Knipe.

To be Flying Officers (Temporary): M. E. Fearnley, J. H. H. Gibbon, G. L. Leathart, J. McE. Neilson, I. R. D. Proctor, W. B. Browne.

#### ROYAL AIR FORCE VOLUNTEER RESERVE

To be Squadron-Leaders (Emergency): D. M. Keir and W. Laurence.

Flight-Lieutenant G. D. Graham, D.S.O., M.B.E., has relinquished his commission on account of medical unfitness for Air Force service, retaining the rank of Squadron-Leader.

Flight-Lieutenants H. O. Williams and R. N. A. Leyton have relinquished their commissions on appointment to the reconstituted A.A.F., retaining their rank.

The notifications in a *Supplement to the London Gazette* dated Aug. 26, p. 4033, column 2, concerning R. A. Sladden and T. S. L. Beswick have been cancelled.

The notification in a *Supplement to the London Gazette* dated Feb. 18, p. 803, column 2, concerning J. Luder, should have read Flight-Lieutenant and not Flying Officer.

Flying Officers H. H. Smith, E. Bindman, A. D. Caird, J. D. C. Campbell, W. A. Crawford, J. S. Creighton, A. Douglas, E. C. K. Douglas, J. M. Fleming, S. Hillman, R. R. Houston, W. M. Layeric, W. A. S. Llewellyn, K. Lowe, A. E. Malone, J. G. Piccaver, G. D. Powell, F. L. Robertshaw, W. E. Robinson, G. E. Schofield, R. E. Sidebotham, A. J. Underwood-Whitney, G. A. Walker, C. G. White, J. R. E. Wilson, and R. E. Woolley to be War Substantive Flight-Lieutenants.

#### AUXILIARY AIR FORCE

To be Flight-Lieutenants: H. O. Williams and R. N. A. Leyton.

#### WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Flight-Lieutenant P. P. Pigott has relinquished her commission on account of medical unfitness for Air Force service, retaining the rank of Squadron-Leader.

#### INDIAN MEDICAL SERVICE

Colonel E. Cotter, C.I.E., has retired.

Lieutenant-Colonel N. M. P. Dotivala, M.C., has retired.

Major E. M. Sewell to be Lieutenant-Colonel. (Substituted for the notification in the *London Gazette* dated Aug. 22.)

Majors G. K. Graham and P. L. O'Neill to be Lieutenant-Colonels.

Captains R. Y. Taylor, W. H. A. Thorne, O.B.E., C. C. Harvey, R. J. McGill, W. W. Coppinger, D. M. Black, N. D. Jekyll, E. J. Somerset, L. D. B. Frost, F. C. Griggs, and A. M. Mackenzie, O.B.E., to be Majors.

#### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

County Borough Councils.—Barnsley, Barrow-in-Furness, Gateshead.

Metropolitan Borough Councils.—Finsbury, Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portlaid, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

Scottish Burghs.—Motherwell, Wishaw.

## Association Notices

#### RADIOLOGISTS GROUP COMMITTEE

As the result of a ballot held to fill the three vacancies upon the Radiologists Group Committee caused by the retirement from the committee of the three members with the longest period of continuous service, the following have been elected members of the committee for the three sessions 1947-50:

S. Cochrane Shanks (London).

C. G. Teall (Birmingham).

B. W. Windeyer (London).

#### CONSULTANTS AND SPECIALISTS COMMITTEE

As a result of the recently held elections the following have been appointed representatives on the Consultants Specialists Committee for the session 1947-8:

Twenty members elected on a regional basis by consultants specialists who are members of the Association and who are engaged exclusively in consultant and specialist practice:

Region 1: Dr. A. A. McI. Nicol, Sunderland.

Region 2: Dr. E. A. Gerrard, Manchester.

Region 3: Mr. J. T. Morrison, Liverpool.

Region 4: Mr. D. Watson, Bradford.

Region 5: Dr. J. W. Brown, Grimsby.

Region 6: Dr. J. F. Brailsford, Birmingham.

Region 7: Mr. J. M. R. Thomas, Norwich.

Region 8: Mr. D. A. Abernethy, Oxford.

Region 9: Mr. C. E. Kindersley, Bath.

Region 10: Sir Eardley L. Holland, London.

Mr. C. I. Naunton-Morgan, London.

Sir Cecil Wakeley, London.

Mr. A. Dickson Wright, London.

Region 11: Dr. R. K. Price, Hove.

Region 12: Mr. N. Ross Smith, Bournemouth.

Region 13: Dr. T. H. G. Shore, Plymouth.

Region 14: Prof. G. I. Strachan, Cardiff.

Region 15: Miss Gertrude Herzfeld, Edinburgh.

Region 16: Dr. W. R. Snodgrass, Glasgow.

Region 17: Dr. F. M. B. Allen, Belfast.

Five members elected on a national basis by members of Association who are engaged part-time in consultant and specialist practice:

Mr. A. H. Baker, Scarborough.

Dr. J. W. Buchanan, Edinburgh.

Mr. W. J. Payne, Darlington.

Dr. C. B. Prowse, Hove.

Dr. W. Yeoman, Harrogate.

#### Diary of Central Meetings

OCTOBER

29. Wed. Council, 10 a.m.

#### Branch and Division Meetings to be Held

BOURNEMOUTH DIVISION.—An evening reception to the members of the Medical Women's Federation, on the occasion of its annual meeting, will be held at the Savoy Hotel, Westcliff, Bournemouth on Friday, Oct. 24, at 8.30 p.m. It is hoped that a considerable number of members of the Division and their wives will attend this function. Those intending to do so should inform the honorary secretary of the Division not later than Oct. 19.

LEWISHAM DIVISION.—At Lewisham Hospital, Sunday, Oct. 27, 10.30 a.m. Clinical meeting arranged by Mr. H. Nockolds.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—At Royal Gwent Hospital, Thursday, Oct. 23, 8.30 p.m. B.M.A. Lecture by Dr. A. E. Clark-Kennedy: Psychosomatic Medicine.

SWANSEA DIVISION.—At Swansea Guildhall, Thursday, Oct. 23, at 7 p.m. for 7.30 p.m. Annual dinner. Owing to the limitation of less than 100 guests at public dinners early application for tickets should be made to the treasurer, Dr. T. W. Davies (110, Skew Road, Swansea).

#### Meetings of Branches and Divisions

##### DUDLEY DIVISION

A meeting of the Dudley Division of the B.M.A. was held on Sept. 12 at the Town Hall, Dudley. The following were present: Dr. Barron (Chairman), Drs. R. D. Gifford, Helen Gifford, Elizabeth O. Aston, G. W. Aston, Jeanette R. B. Gibson, B. G. Gretton, J. Macdonald, W. Nasmyth-Miller, D. Little, N. V. Hepple, H. W. Bland, J. Sexton, J. Martin, G. J. Meldon, H. McEvoy, A. C. Parnell, J. Ribchester, L. H. Eynson, W. S. Coutts, J. B. Collins, K. A. Farrell, Lois Davis, S. Walker, A. Rosenbaum, G. Dudley, H. W. Plant. Before the meeting began the members together with a number of health visitors and other medical practitioners, saw the film called "The Early Diagnosis of Acute Anterior Poliomyelitis." Prof. J. Smellie led an interesting discussion. A letter was read from the County M.O.H. of Staffordshire asking for a nominee to a committee which is to meet at Stafford to discuss the new Health Act. The names of Dr. R. D. Gifford and Dr. L. H. Eynson were proposed and seconded. On a vote being taken Dr. R. D. Gifford was nominated. A letter from the Secretary of the B.M.A. was read asking for volunteers to assist the Benham Committee for Poor Litigants. It was agreed that any member who desired to assist in this way should send his name to the Hon. Secretary of the Dudley Division. A further letter from the Hon. Secretary of the B.M.A. was read on the remuneration of district medical officers. It was agreed to call a meeting of all the district medical officers in the Division in the near future to discuss the matter fully.

LONDON SATURDAY OCTOBER 25 1947

## AETIOLOGY OF STEATORRHOEA\*

BY

A. C. FRAZER, M.D., D.Sc., M.R.C.P.

Professor of Pharmacology, University of Birmingham

Steatorrhoea is commonly observed in cases of tropical and non-tropical sprue, coeliac disease, pancreatitis, gastro-colic fistula, and a number of other conditions. The percentage of fat in the faeces is, however, a misleading index, except in gross cases, and the diarrhoea is due to factors not entirely related to the underlying primary defect. In studying the aetiology of steatorrhoea it is therefore better to study the whole group of cases with defective fat absorption rather than to confine the investigation to severe cases of fatty diarrhoea. A balance test, based on the measured intake and output of fat, is the criterion by which the normality or otherwise of fat absorption is judged. A normal human subject on a diet containing 50 g. of fat absorbs 95% or more of the fat ingested. Fat absorption may be regarded as defective in all cases absorbing 90% or less. Repeated tests are advisable in the doubtful zone of 90 to 95%. These figures are based on an assumption that the excretion of fat is not greatly altered in the cases under investigation. The rapid response to changes in dietary fat and the immediate reduction of faecal fat to normal levels on ingestion of a low-fat diet support the view that changes in fat excretion are not a major factor in the cases so far investigated (Cooke *et al.*, 1946).

Fat absorption may be divided into three phases: an intraluminal phase, during which the fat is prepared for absorption; an intracellular phase, in which the fatty material passes through the intestinal cell; and a distributive phase, when the fat is dispersed from the intestine by various pathways into the body. In each of these phases the normal mechanism of absorption, the methods of study in the human subject, the observations made in cases of defective absorption, and the possible significance of these observations in the aetiology of steatorrhoea will be discussed.

### Intraluminal Phase of Fat Absorption

Fat is mainly ingested as triglyceride, and there is no doubt that this fat is finely dispersed to an emulsion of particle size of less than  $0.5 \mu$  diameter in the lumen of the small intestine. In the normal subject the pH in the upper two-thirds of the intestine is acid (about 6.5). Fine dispersion of triglyceride at this pH requires a specialized emulsifying system. If the possible factors are tested in various combinations, only one system can be shown to be effective under these conditions *in vitro*. This is the triple combination fatty-acid-bile-salt-monoglyceride (Frazer, Schulman, and Stewart, 1944). The formation of fatty acid and monoglyceride can be shown to occur during the first five hours of pancreatic lipolysis *in vitro* (Frazer and

Sammons, 1945). This partial lipolysis provides two of the three essential components of the emulsifying system. If material is removed from the lumen of the intestine in either rats or human subjects during fat absorption the presence of these three essential components in adequate quantities can be demonstrated.

The intraluminal changes have been studied in human subjects by passing a Miller-Abbott tube a measured distance down the small intestine. The intestinal lumen was obstructed by inflation of the bag on the end of the tube and a resting sample of intestinal contents was obtained from the region above the point of obstruction. Oil was

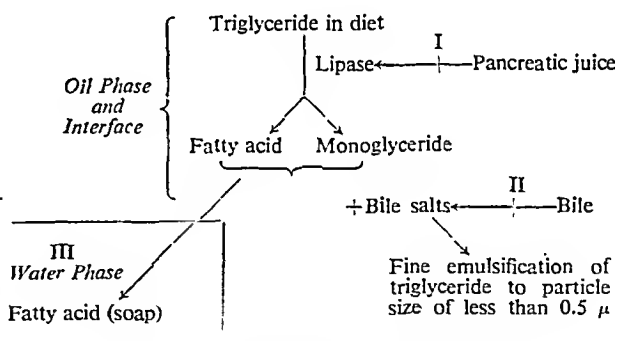

FIG. 1.—Intraluminal phase of fat absorption.

#### Possible Defects:

- I. Defective lipolysis—e.g., atrophic pancreatitis.
- II. Defective bile salts—e.g., biliary obstruction.
- III. Influenced by environment or nature of triglyceride (see Fig. 3).

now administered by mouth and samples of intestinal contents withdrawn at intervals for the next four hours. The various samples were examined for enzyme activity, and the fatty material was analysed chemically and investigated by protein flocculation (Elkes *et al.*, 1945) and other techniques to determine the nature of the interfacial film covering the oil globules. The degree of dispersion of the fat was determined by microscopical examination under dark-ground illumination. The intestinal contents of normal subjects contained lipase, trypsin, and amylase. The fat was finely dispersed to a particle size of less than  $0.5 \mu$ , the particles were negatively charged, and did not contain phospholipid as an essential part of the stabilizing system. Fatty acids, monoglycerides, and bile salts were present. The pH of the intestinal contents was 6.5, or more acid. Of the cases of defective fat absorption studied, only two groups showed abnormal intraluminal changes. Cases of biliary obstruction or hepatic cirrhosis, in which bile salts were not

\*Based on a paper read to the Paediatrics Section of the International Conference of Physicians, London, Sept. 10, 1947.

passed into the lumen, showed poor emulsification of the fat, with large particles of oil which were not finely dispersed by agitation of the samples. After addition of bile salts to this material, emulsification rapidly occurred. In a case of atrophic pancreatitis, subsequently proved at necropsy, emulsification was also grossly deficient; and in this case there was a complete absence of pancreatic enzymes in the upper intestinal contents. The addition of bile salts was not effective in this case, but the addition of lipase caused immediate fine emulsification. The intestinal contents of all other varieties of defective fat absorption so far examined, including tropical and non-tropical sprue and regional ileitis, have shown normal dispersion of fat and apparently normal enzyme activity. The pH of the intestinal contents in some of these cases has been somewhat higher than normal, but the validity and significance of this observation is being further investigated. In a small number of cases of tropical sprue, investigated with Squad-

### Intracellular Phase of Fat Absorption

The passage of fatty material through the intestinal cell presents three main groups of problems:

#### (a) Passage of Fatty Material through the Outer Membrane of the Cell

Many water-soluble materials appear to pass through the outer membrane of the intestinal cell, although the precise mechanism of absorption and the factors responsible for the differences in the rate of transmission of water-soluble substances are still obscure. It can be shown that fatty acid will pass into the intestinal cell, possibly in the form of soap (Schmidt-Nielsen, 1946). It is probable, however, that the hydrolysis of long-chain fats is only partial in the upper part of the small intestine, and consequently a second mechanism must exist for the passage of water-insoluble glycerides through the outer membrane.

	Main Forms of Fatty Material	Dispersion of Particulate Fat	Factors concerned in Passage through Membrane	
Lumen	Triglycerides Monoglycerides Fatty acids	Particle size: $0.5 \mu$ Charge: negative Interfacial film: fatty-acid-bile-salt-monoglycerides Phospholipid not involved	Fatty acid	Finely dispersed triglycerides
Outer Membrane				Normal water and electrolyte metabolism (adrenal cortex) I
Cell	Triglycerides (Monoglycerides) (Fatty acids) Phospholipids	Particles increase in size ? change of interfacial film	?	Phospholipid formation II
Inner Membrane				Choline III
Corium of Villus				
Thoracic Duct	Triglycerides Phospholipids			
Systemic Blood	Triglycerides Phospholipids	Particle size: $0.5 \mu$ Charge: negative Interfacial film: contains phospholipid as essential part of the stabilizing system		

FIG. 2.—Intracellular phase of fat absorption.

#### Possible Defects:

- I. Interference with water and electrolyte metabolism—e.g., adrenalectomy: Addison's disease.
- II. Defective phosphorylation
- III. Defective transport from the cell

Possible defects in "sprue syndrome." (NOTE.—Fatty acid absorption will not be prevented by these lesions.)

Dr. G. A. Smart and R. Daley (1946), we observed a peculiar flocculation of the intestinal contents, the cause of which we were unable to establish. Unfortunately, further cases were not available and we have not seen this phenomenon in any other patients.

It may be concluded from these various observations that long-chain triglycerides are partially hydrolysed in the upper part of the small intestine to fatty acids and lower glycerides, and that these two substances, with bile salts, provide the emulsifying system by which the remaining glycerides are dispersed into fine particles of less than  $0.5 \mu$  diameter. These changes would appear to occur normally in tropical and non-tropical sprue and in regional ileitis, but they do not occur in conditions which interfere with any of the essential components of the emulsifying system. Thus exclusion of pancreatic lipase, or of bile salts, resulted in gross interference with the preparatory changes which triglyceride undergoes in the intestinal lumen.

Long-chain triglycerides are finely dispersed to a particle size of less than  $0.5 \mu$  in the intestinal lumen by the emulsifying system already described; the outer membrane of the intestinal cell has been shown by Baker (1942) to consist of fine canals, which might allow the passage of particles approximately  $0.3 \mu$  in diameter. Paraffin can be absorbed from the intestine, provided that it is previously dispersed with a suitable emulsifying system to a particle size of less than  $0.5 \mu$  (Frazer, Schulman, and Stewart, 1944). Thus the evidence at present available supports the conception that long-chain triglycerides may pass through the outer membrane of the cell in fine particulate form.

The first step in the study of this phase of absorption in the human subject is to determine, if possible, whether the defect is concerned with the passage of fatty acid or of particulate fat through the cell. It seems probable that the post-absorptive systemic lipaemia is normally dependent upon particulate absorption. By the correlation of chyl-

icrographs (Frazer and Stewart, 1939) or serial blood fat timations with a fat-balance test it is possible to determine hether particulate absorption is normal. In cases showing ormal intraluminal changes, in the absence of lymphatic obstruction, the absorption of 60 to 70% of ingested fat, ithout any subsequent systemic lipaemia, strongly suggests terference with particulate absorption. Such a phenonon is observed in tropical and non-tropical sprue and in cases of gastro-colic fistula. In regional ileitis, on the other and, normal systemic lipaemia may be observed although e total amount of fat absorbed is no greater than in many ases of the sprue group. It is possible that interference ith particulate absorption may lead to the absorption of a increased proportion of fatty acid. This possibility is urther discussed in the section on the distributive phase.

Adrenalectomy does not affect the absorption of fatty acids or tributyrin but seems to cause partial interference ith the absorption of long-chain triglyceride. The load- ing of the intestinal cell with fat globules, which is charac- teristic of particulate absorption, is prevented by adrena- lectomy. Adrenalectomy does not cause any change in the rmoval of phospholipid in the intestinal cell. The absorp- tion of long-chain triglycerides returns towards normal ith adequate salt therapy (Bavetta and Deuel, 1942; Frazer, 1947; Stillman *et al.*, 1942). It seems possible, therefore, hat the action of the adrenal cortex on fat absorption is ainly due to its effect on water and electrolyte metabolism, hich may be intimately associated with the mechanism of articulate absorption.

Severe cases of sprue may show a marked disturbance of water and electrolyte metabolism (Black, 1946). Dehydra- tion is a pronounced feature in the terminal stages, and less vere cases may exhibit low blood sodium levels and ypotension. Severe cases of Addison's disease may show moderate degree of defective fat absorption. It has been uggested that adrenal cortical deficiency may be an aetio- logical factor in the sprue syndrome (Verzár and McDougall, 1936). On the other hand, patients with non-tropical sprue an be relieved of any suggestive signs of adrenal insuffi- ciency by appropriate treatment without any change in the quantitative aspect of the fat-absorption defect. It is not possible that the continued low blood cholesterol which s usual in these cases may result in a secondary insufficiency of adrenal cortical hormone. It seems probable from these bservations that adrenal cortical insufficiency is not an aetiological factor in the sprue syndrome, but it is likely that he secondary disturbances of water and electrolyte meta- bolism, whether due to adrenal cortical insufficiency or to other causes, would further embarrass a defective fat- absorption mechanism.

#### (b) Alteration in the Composition and Distribution of Fatty Material within the Intestinal Cell

Under special experimental circumstances re-synthesis of triglyceride can be demonstrated *in vivo*, as indeed it can also be demonstrated *in vitro*. There is little evidence, however, to suggest that it is an important feature in normal fat absorption, especially if a high proportion of the fatty material passes into the cell in the unhydrolysed form.

It has been clearly shown that phospholipid is formed in the cell during fat absorption (Schmidt-Nielsen, 1946; Sinclair, 1936). The function of the phospholipid formed in the intestinal cell is not understood, but certain observa- tions may usefully be considered. The particles of fat in the intestinal lumen are negatively charged, flocculate with plasma protein at pH 7.4 (Elkes *et al.*, 1945), and are resis- tant to the action of *Clostridium welchii* D-lecithinase (Elkes and Frazer, 1943). In the intestinal cell, if fat alone is fed, the particles show a loss of stability, which suggests that

the effective stabilizing film has been modified and that there is interference with the provision of a new stabilizing film under the conditions of this experiment. Triglycerides and phospholipid, but only small amounts of fatty acids or lower glycerides, can be demonstrated in the chyle during fat absorption. In the blood at the height of fat absorption a mass of finely dispersed particles, composed essentially of triglycerides, can be seen, which obviously do not flocculate in the presence of plasma proteins at pH 7.4. Furthermore, these particles rapidly cream when attacked by *Cl. welchii* D-lecithinase. It seems possible, therefore, that one im- portant function of phosphorylation in the intestinal cell is to provide phospholipid for the change in interfacial film structure which must occur if the fat particles are to remain in a dispersed state in the protein environment of the blood stream.

#### (c) Passage of Fatty Material through the Inner Membrane of the Cell

The passage of fat through the inner membrane of the intestinal cell has received little attention. From the study of intra-vitam fixed preparations of the rat's intestine, the distribution and state of dispersion of absorbed fat in the cell and villus can be investigated. If fat and water alone are fed, the fatty material passes freely through the outer border of the cell. As the dose of fat is increased, fat accumulates within the cells. If a loading dose is administered with 5 mg. of choline hydrochloride, dissolved in the water phase, accumulation of fat in the cells is less marked and a large amount of fat can now be seen in the corium of the villus. It would seem, therefore, that the addition of choline to the fat in some way facilitates its passage through the inner membrane of the cell. A striking feature of these preparations, however, is a further loss of stability of the fat particles, so that large pools of fat are formed in the central part of the villus (Frazer, 1947).

It is often assumed that the phospholipid formed in the intestinal cell during fat absorption is lecithin. It is quite possible that other phosphatides may be involved, especially in the change of the interfacial film of the fat particle. Whether the effect of choline is related to the phosphoryla- tion process in the cell is not known. Until further evidence is available it would be wise to consider the action of choline and the formation of phospholipid in the intestinal cell as two possibly unrelated phenomena.

The existence of a defect in phosphorylation has been cited as a possible aetiological factor in the sprue syndrome (Verzár, 1935; Stannus, 1942). Direct evidence in support of such a conception is lacking, although the gradual elimi- nation of other possibilities suggests that an intracellular defect may be important in many of the cases in this group. It is likely that a number of different aetiological factors, each of which may perhaps result in the same fault in the fat-absorption mechanism, may be concerned in the sprue syndrome. For example, phosphorylation in the intestinal cell might be prevented by an intracellular enzyme defect, or by lack of raw materials for phosphorylation, which in turn might be occasioned by dietary deficiency, by defective digestion elsewhere, or by competitive demands in the intestinal lumen. Until more adequate information is available as to the nature of the phospholipid formed, the factors governing its formation in the intestinal cell, and the function which it fulfils, it is difficult to develop effective methods for the detection and differentiation of these defects in the human subject.

Some years ago Mottram, Cramer, and Drew (1922) reported findings somewhat similar to the choline experi- ments described above when they administered "marmite"

with fat. They attributed the effect observed to the actions of vitamins A and B. Consequently the effects of vitamins A, C, and D and the various components of vitamin B on the fat-absorption mechanism were investigated along the same lines as the choline investigation. None of these substances, with the exception of choline, had any apparent effect on the distribution of fat in the intestinal cells and villi during absorption.

Deficiencies of riboflavine or nicotinic acid are frequently associated with fat-absorption defects, especially the sprue syndrome. It is possible, however, to give dramatic relief to deficiency signs and symptoms by administration of the appropriate vitamin fraction without any measurable change in the fat-absorption defect. Cases have also been reported of ariboflavinosis and other vitamin deficiencies in which fat absorption was normal. Gross vitamin deficiency, which is not a feature of the sprue syndrome, may result in structural and metabolic changes with which failure of absorption of fat and other substances may be associated. It would seem, therefore, that in the sprue syndrome deficiency of vitamins is not a constant feature; that the symptoms and signs observed indicate only a relative rather than a gross deficiency, and that a selected group of vitamins are involved, especially riboflavine, nicotinic acid, and possibly other members of the B complex. The diet of these patients is not usually deficient in these vitamins, so that the defect must be due either to adverse circumstances in the intestinal lumen, to defective absorption, or to faulty utilization. It may be coincidental that many of the associated deficiencies observed in cases of the sprue syndrome are concerned with substances which have a nutritional significance both to bacteria and to human subjects, and that bacteria are present in large numbers in the upper part of the small intestinal tract in the cases so far investigated. It does not seem impossible that competition might arise between the nutritional demands of these organisms and the host, somewhat analogous to that observed with other intestinal parasites. Further investigations on a quantitative basis must decide whether these deficiencies are due to some such competitive phenomenon, to malabsorption, or to faulty utilization. It may, however, be concluded that vitamin deficiencies, possibly excluding choline, are probably not concerned with the aetiology of the fat-absorption defect in the sprue syndrome.

#### Distributive Phase of Fat Absorption

It can be shown by experiment that fatty acids mainly pass up the portal vein to the liver, like other water-soluble materials, while triglycerides, absorbed largely in particulate form, take the lymphatic route and pass by the thoracic duct into the systemic circulation (Frazer, 1943a). It is obvious, therefore, that the proportion of fatty material which passes by these two alternative routes might be considerably varied without any great change in the total quantity of fat absorbed. Differences in the extent of the systemic lipaemia, probably due to the change in the proportion of fat absorbed in particulate form, may be induced in animals and human subjects by procedures designed to alter the extent of lipolysis (Frazer, 1943b). It has already been noted that many cases of defective fat absorption, especially in the sprue group, may absorb as much as 70% of ingested fat without any appreciable systemic sequelae. The amount of fat absorbed in these cases would normally give rise to a marked systemic lipaemia. It is of interest, therefore, to consider the factors that might be concerned in a change of distribution of fat from the lymphatic to the portal pathway.

It is clear that an obstruction to the lymphatic pathway might effectively prevent the normal systemic sequelae during fat absorption. It is interesting that in such cases,

and in experimentally induced obstruction, the quantitative decrease in fat absorption is much less than might be expected, suggesting that when the lymphatic pathway

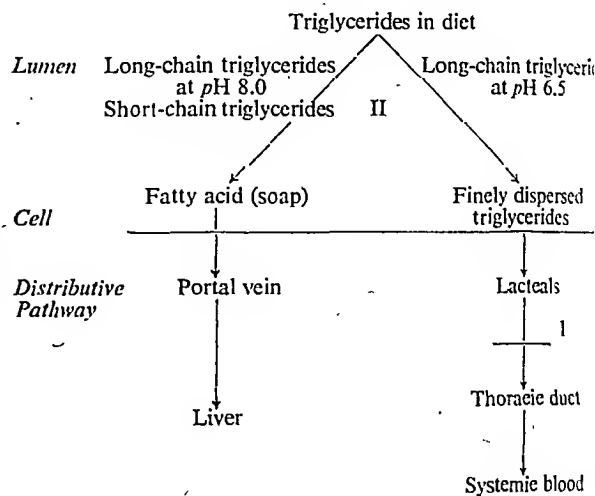

FIG. 3.—Distributive phase of fat absorption.

#### Possible Defects:

- I. Lymphatic obstruction.
- II. (a) Primary change in intraluminal environment or variation in diet.
- (b) Secondary changes in intraluminal environment in cases of defective particulate absorption.

interrupted an increased proportion of fatty material pass by an alternative route. In the large majority of cases defective absorption examined there is no evidence of obstruction to the lymphatic pathway, and alteration of the distribution of the fatty material must be dependent upon changes in the lumen or cells of the intestine.

It is generally agreed that hydrolysis of long-chain triglycerides is restricted to about 30% *in vitro* unless very specialized conditions prevail. It is, however, claimed that in the intestinal lumen the fatty acid formed is absorbed and consequently hydrolysis proceeds rapidly to completion. It can, however, be shown that the restricting factor for hydrolysis of long-chain triglycerides is the accumulation of fatty acid at the interface of the oil globules rather than accumulation in the water phase. This restriction can be overcome only by the removal of the fatty acid into the water phase, which is necessary before its absorption from the lumen of the intestine can occur. This has only been achieved experimentally to any significant degree by conversion of the fatty acid into soap. The formation of soap in this way is largely conditioned by the pH of the environment, being very slow at pH 6.5 but more effective at pH 8.0. It may also be noted that the optimum pH for the action of pancreatic lipase is 8.0 to 8.5, and the activity of the enzyme is considerably diminished at pH 6.5. If the hydrolysis of a short-chain triglyceride, such as tributyrin, is studied, restriction does not occur, since the butyric acid is water-soluble and can be freely removed from the interface, independently of the pH of the environment.

In the lumen of the normal intestine the pH of the contents of the upper two-thirds is 6.5, while a more alkaline reaction, up to pH 8.0, may occur in the lower end of the ileum. The hydrolysis of long-chain triglycerides is therefore likely to be restricted in the upper part of the small intestine, but more extensive breakdown might occur towards the lower end. Since active absorption of fat is known to occur from the mid-duodenum downwards, it must be concluded that long-chain triglycerides are absorbed mainly in particulate form in the upper intestine, but a greater proportion may pass through as fatty acid in the

leum. Tributyrin, on the other hand, will be rapidly hydrolysed and absorbed as fatty acid. In this connexion it may be significant that the absorption of tributyrin is not affected by adrenalectomy (Bavetta and Deuel, 1942), and tributyrin is not found in the chyle (Hughes and Wimmer, 1935) or in the fat depots (Davis, 1930). The behaviour of triglycerides containing fatty acids of chain length intermediate between these two extremes is not yet known. It is of some interest, however, that the tolerance of patients with fat-absorption defects to different dietary fats appears to vary considerably.

If the pH in the upper part of the small intestine can be altered towards the alkaline side, more extensive hydrolysis might occur, with a corresponding decrease of particulate and increase of fatty acid absorption. The effect of such a change on the total efficiency of the fat-absorption mechanism is not known, but it seems unreasonable to suppose that the absorption of fatty acid from the intestine is already maximal under normal circumstances. Thus the sequelae associated with particulate absorption would be suppressed, but the total quantity of fat absorbed might not be greatly altered. Such a change might be a primary factor in the alteration of the fat-absorption pattern, or it might be secondary to a defect in particulate absorption. It is known that changes in the intestinal environment occur in a number of cases of defective fat absorption, but whether these are primary or secondary, or to what extent they are significant, has not yet been established. It may, however, be concluded that fat can be absorbed by at least two distinct mechanisms, each of which uses a different distributive pathway. The proportion of fat which is absorbed in particulate form may be reduced, with a corresponding increase in fatty acid absorption. Such a mechanism would provide the flexibility which is apparent in cases of defective absorption. The main factors which seem to be concerned in changes in the distributive phase, apart from obstruction to the lymphatic pathway, are the pH in the intestinal lumen and the composition of the dietary triglyceride.

The original material contained in this paper is largely due to the efforts of a number of colleagues in Birmingham with whom it has been my privilege to work. I am particularly indebted to Prof. T. L. Hardy and Dr. W. T. Cooke for guidance in the clinical field; to Miss M. D. Thompson for most of the clinical investigations, especially the intubation experiments; to Dr. H. G. Sammons and to Dr. Garfield Thomas for biochemical assistance; to Dr. A. L. Peeney for bacteriological studies; to Dr. J. M. French and Mr. P. E. Sagrott for assistance with the experimental work; and to the Medical Research Council and the Sir Halley Stewart Trust for their financial help.

SOME PROBLEMS OF TROPICAL  
SPRUE\*

BY

D. A. K. BLACK, M.D., M.R.C.P.

Lecturer in Medicine, University of Manchester

AND

L. P. R. FOURMAN, M.D., M.R.C.P.

Assistant, Nuffield Department of Clinical Medicine, Oxford

Before describing some of our observations in early tropical sprue it will be well to make two introductory digressions—the first on current views of fat digestion and absorption, the second on the type of patient with whom we were dealing.

## Fat Digestion and Absorption

The classical view, of which a full statement is given by Bloor (1943), maintains that any absorption of dietary fat is preceded by splitting of the fat into glycerol and fatty acid. The glycerol is absorbed as a simple water-soluble substance and the fatty acid is absorbed as a water-soluble complex with bile salts, as cholesterol ester, or as phospholipid. The importance of phosphorylation in the absorption of fatty substances has been emphasized by Verzar, but not all of his supporting data have been confirmed.

Over the past ten years or so Frazer (1946) and his co-workers have collected a substantial body of evidence in favour of his "partition hypothesis" of fat absorption. In his view some of the fat is absorbed without preliminary splitting, so that there are two virtually independent channels of fat absorption. Neutral fat is absorbed as a very fine emulsion, and Frazer has described an emulsifying system of bile-salt-mono-glyceride-fatty-acid which is adequate to produce an emulsion of the required fineness. Moreover, absorbed neutral fat enters the lacteals, and ultimately the systemic blood stream, where it may be visible as finely divided fatty particles known as chylomicrons; split fat, on the other hand, enters the portal blood stream and may therefore be absorbed without necessarily increasing the chylomicrons in the systemic blood. In support of his view Frazer has shown that liquid paraffin, which cannot be "split," can yet be absorbed if it is emulsified sufficiently. If rats are given a fatty meal with added lipase, so that splitting is practically complete, fatty particles are demonstrable in the portal blood; if, on the other hand, the fatty meal is treated with sodium cetyl sulphate, which inhibits lipolysis, fatty particles are found in the thoracic lymph and not in the portal blood stream.

Our own limited experience in this field has convinced us of the correctness of Frazer's views, with two minor reservations on quantitative grounds. The possibility of neutral fat absorption seems to be proved, but what proportion of the dietary fat is absorbed in this way is still uncertain; secondly, we found the chylomicron count was of very limited value as a measure of fat absorption, in view of the great variation in the size of the particles seen, which meant that identical "counts" might represent very different amounts of "chylomicron-fat."

*Clinical Features of Early Sprue.*—This is not the place for a clinical description of the textbook type, but it may be said that all the patients investigated showed loss of weight, abdominal distension, and fatty stools. Tongue changes were less constant, and anaemia of any severe degree was uncommon, nor was it necessarily macrocytic in those patients who showed it. Tetany and bone changes

\* Based on a lecture given by one of us (D. A. K. B.) at the British Postgraduate Medical School.

were not seen, perhaps because alimentary absorption of vitamin D is not as essential in a tropical as in a temperate climate. About one patient in ten had profuse watery diarrhoea in place of the more usual bulky formed stools; such patients tended to go downhill rapidly, with low blood pressure, asthenia, and dehydration—a type of the disease which may be referred to shortly as “severe sprue.”

**Objects of the Investigation.**—Although much work has been done on the clinical and haematological aspects of sprue, notably by Castle *et al.* (1935) in Porto Rico, there is surprisingly little information on the quantitative aspects of fat absorption. Since the steatorrhoea is one of the outstanding features of sprue, it was decided that our main aim should be to collect data on fat absorption in early cases and see how the absorption might be affected by different forms of treatment. Some data were also obtained on the absorption of non-fatty substances, and an attack was made on the problem of “severe sprue,” already referred to.

### Fat-absorption Studies

Three methods of studying fat absorption were used—chylomicron counts, serum lipid curves (Black and Simpson, 1947), and fat-balance experiments (Black, Bound, and Fourman, 1947). As experience with these various methods grew we found ourselves relying more and more on the fat-balance technique, but the results of the other methods may be briefly described. Chylomicron curves turned out to be fairly normal in most cases of early sprue. In some patients the chylomicron curve was below the rather wide normal range; but this type of curve was constantly present only in those patients who had profuse watery diarrhoea. Serum lipid curves were obtained by giving a standard meal of tinned milk containing 18 g. of fat, and analysing samples of serum taken off fasting, and 2½, 3, 3½, and 4 hours after the meal. The total fatty acid, cholesterol, and lipid phosphorus were directly determined, and from these data values were calculated for cholesterol-ester fatty acid, phospholipid fatty acid, and, by difference, neutral-fat fatty acid.

There was a significant difference between the fasting values in nine normal subjects and 16 patients with sprue; the total fat in the sprue patients was only slightly lower than in the normal subjects, but the cholesterol and phospholipid fatty acid was markedly lower, while the neutral fat was actually higher in the sprue patients. After the meal the increment in total fatty acid in the sprue patients was only about half that in normal subjects; neutral fat increment was much less affected than phospholipid fatty acid increment, while cholesterol fatty acid showed an actual fall in the sprue patients after a fatty meal. Unfortunately the normal range of fat curve was very wide, so that in the individual patient with sprue the curve might well fall within the normal range. This impairs the value of fat curves both in diagnosis and in investigation.

### Fat-balance Experiments

Two diets of known fat content were available to us—one containing 65 g. of fat a day, the other 95 g. We measured the total output of fat in the stools and by subtraction from the dietary fat arrived at the total amount of fat absorbed; this, when expressed as a percentage of the dietary fat, may be termed the percentage fat absorption. Questions of interpretation arose very early in the course of this work.

1. It was found that the variation between successive four-day stool collections was very great, and in order to reduce error from this cause we have considered all our results in terms of twelve-day periods.

2. Any true intestinal excretion of fat will introduce error into this assessment of fat absorption. It was found, however, that sprue patients on a low-fat diet excreted no more fat than

normal people, so true excretion of fat can introduce only small systematic error.

3. As patients originally on a 65-g. fat diet improved under treatment it often became necessary to increase their diet to 95 g. of fat a day. In five patients in whom this was done the percentage fat absorption was found not to change significantly. Apart from its practical bearing on the validity of percentage fat-absorption measurements on different diets, this result has some theoretical significance. It suggests that the impairment in absorption is not a fixed mechanical deficiency, as added fat would in that case be excreted quantitatively and the percentage fat absorption would decrease in the higher diet. On the other hand, an alteration in one of the enzyme systems connected with fat absorption would be expected to give this type of result. It is also possible, of course, that on the higher fat diet the increase in the gastric emptying time is great enough to ensure that the amount of fat actually presented to the intestine for absorption in unit time is not increased. From a more practical point of view it is to be noted that the increase in the fat content of the diet in these patients was a very moderate one, and our results do not conflict with the general experience that it is inadvisable to give large amounts of fat to patients with active sprue. Normal people taking a mixed diet containing 50 to 100 g. of fat a day will absorb over 90% of the dietary fat. In 28 patients with early tropical sprue we found that the fat absorption ranged from 50 to 85%. There was, therefore, with this method of assessment a clear-cut distinction between normal people and sprue patients, a distinction which was conspicuously lacking with the other methods which we tried as measures of fat absorption.

It is to be noted that Cooke *et al.* (1946), using a fat balance method, also found a different range of fat absorption in normal subjects and in patients with idiopathic steatorrhoea. Results of this type commend the fat-balance technique, in spite of its tedium, as a means of assessing the severity of steatorrhoea and following progress under treatment.

In therapeutic trials with nicotinic acid and riboflavin in large doses the patients showed no improvement either in their clinical state or in fat absorption. With large doses of a crude liver extract given parenterally there was rapid clinical improvement, with gain in weight and well-being and improvement in the character of the stools. In spite of this the percentage of fat absorption showed no detectable change in several weeks of liver therapy and thereafter improved only slowly as the patient's general state approached the normal. When yeast extract in a dose of 15–20 g. daily was given to patients while on their liver treatment there was some improvement in fat absorption within the first twelve-day period. We had not the opportunity ourselves to observe the effect of folic acid in tropical sprue, but results reported by Davidson *et al.* (1947) suggest that it has an action rather like that of crude liver extract and inferior to yeast extract, at least as regards fat absorption.

### Absorption of Non-fatty Substances

Apart from glucose, the absorption of non-fatty substances in sprue has been little studied; yet it would seem important in considering the aetiology of the disease to know whether the impairment of absorption is general or whether it is limited to a few substances—such as fat—absorption of which may present some special difficulty, or perhaps even whose failure to be absorbed is more readily apparent from secondary effects on the stools. If unabsorbed carbohydrate were as easily recognized in the stools as unabsorbed fat the demonstration of impaired carbohydrate absorption in sprue might not have to be based on the equivocal evidence of blood-sugar curves, so easily modified by non-absorptive factors. The evidence which we obtained on the question of non-fatty absorption in tropical sprue is mostly indirect. for the balance technique of studying absorption cannot

e applied to substances such as glucose or amino-acids. Some general impairment of absorption was suggested by our finding that in the active stages of sprue the dry weight of the stools was increased to a greater extent than could be accounted for by their increased fat content. Using indirect methods, we confirmed that glucose absorption is often impaired, and we also found some evidence of faulty absorption of iron, sodium, and chloride in certain cases. On the other hand, iodide and amino-acids were abnormally absorbed. Iodine is absorbed from the stomach and so is rather a special case.

The satisfactory absorption of amino-acids does show, however, that the intestinal absorption defect is not universal; the exact process involved in amino-acid absorption is not known, but absorption is more rapid than can be accounted for by simple diffusion (Höber, 1945). Fourman (1947) has found evidence of impaired xylose absorption in sprue: this may imply a more fundamental absorption defect than that shown by flat glucose curves, since xylose absorption, unlike that of glucose, is not inhibited by phloridzin and may therefore be produced by a different and simpler mechanism.

In summary, the evidence suggests that there is in fact a fairly general impaired absorption in sprue, and that fat malabsorption has been first observed only because its effects on the stools are more obvious.

#### Salt Deficiency

In preliminary work on the syndrome described above as "severe sprue" it was found that the serum sodium and chloride were both low. A balance experiment showed that large amounts of sodium and chloride were being lost in the watery stools, and that sodium was practically absent from the urine although chloride was still present in about half the normal amount. This is the biochemical pattern of salt deficiency (Black, 1946) accompanied by some acidosis; the absence of sodium from the urine is very much against suparenal insufficiency being the cause of the hypotension—a suggestion made by Thaysen (1932). The persistence of some chloride in the urine may be misleading if reliance is placed on the urinary chloride alone in detecting salt deficiency in this type of patient.

#### Conclusion

We would emphasize the two findings which seem to us of practical therapeutic significance. The first is that yeast extract in large doses has a favourable effect on fat absorption: we have seen clinical benefit from yeast treatment in patients with chronic sprue in this country, and it is more convenient for the patient than frequent injections of crude liver extract. Secondly, a number of patients with sprue became acutely ill, with salt-deficiency dehydration associated with watery diarrhoea; in such patients the diarrhoea must be controlled with sulphaguanidine and parenteral liver, and their diet should also be supplemented with moderate amounts of salt.

## SHOCK IN OBSTETRICS

BY

W. A. SCOTT, F.R.C.Sed., F.R.C.O.G.

Professor Emeritus in Obstetrics and Gynaecology,  
University of Toronto

The essential mechanism of surgical shock is yet to be definitely established. It is understandable, therefore, that the physiologists and experimental surgeons desire to keep surgical shock in a special category until the mechanism of its inception may be discovered. As regards this subject I am neither a physiologist nor an experimental surgeon, and I speak, therefore, simply as a clinician. To the clinician there is a group of cases characterized by circulatory deficiency, with low blood pressure, decreased blood volume, decreased cardiac output, and increased concentration of blood that present a common clinical picture irrespective of the primary cause. These patients present a group of symptoms and not a disease. The prevention and treatment of these are of primary importance, and whether there is a special kind of shock called "obstetric shock" occurring in normal women after normal labour is of little importance. At one time it was customary to attribute a certain number of sudden deaths during or after labour to primary shock; but Sheehan, as well as other observers, has made it quite clear that in the great majority, if not all, of these cases necropsy will reveal some condition sufficient to account for the fatality.

In all urban centres the number of maternal deaths certified as due to "shock" is a great deal less than it was twenty-five years ago. Of 122 maternal deaths during a two-year period from May, 1938, carefully evaluated by the Department of Health and Welfare of the Province of Manitoba, five were originally attributed to "strain and shock." Two of these, on review of the clinical history, were obviously due to internal haemorrhage, and the other three, on review, could not easily be attributed to shock. All five of these patients were delivered at home, remote from hospitals, and necropsies were not done.

Table I is an analysis of the maternal deaths with clinical evidences of shock in the Province of Ontario for 1943, the last year for which complete data were available.

TABLE I.—Maternal Deaths Accompanied by Shock: Province of Ontario, 1943

Total live births	..	81,173
Maternal deaths—exclusive of ectopic gestation (14)	..	189
Maternal deaths with clinical evidence of shock	..	82
Pulmonary embolism	..	33
Haemorrhage	..	31
Failed forceps and version	..	5
Difficult forceps	..	5
Rupture of the uterus	..	5
Acute dilatation of the stomach (necropsy)	..	1
Normal delivery with severe hypertension	..	1
Normal delivery with no apparent haemorrhage (no necropsy)	..	1

It will be seen that at the most only 11 of these did not have definite lesions accounting for the shock, and of the 11 there were 5 versions after failed forceps and 5 difficult forceps cases, in most, if not all, of which there was probably severe injury to the birth canal, with haemorrhage.

It is my opinion that, from the clinical point of view, the great majority of cases of obstetric shock can be evaluated in terms of haemorrhage. That is not to say that other causes of shock do not occur in the parturient patient: it is to say that they are relatively infrequent.

Table II summarizes the cases of shock on the public ward service of the Toronto General Hospital for the period 1931–43.

In the third group, with a blood loss of more than 1,000 ml., it will be noted that there were 6 deaths. Two of these were cases of placenta praevia; both had severe haemorrhages before admission and were bleeding when

admitted. Both cases had immediate transfusion and were treated by version. I would like to point out that this method of treatment is rarely employed in our service, and that there were particular circumstances which seemed to warrant it in these instances; but probably both cases were errors of judgment. One of these patients died following post-partum haemorrhage. The second patient recovered from her shock, had a spontaneous delivery but a post-partum haemorrhage, and died in two hours in spite of further transfusion.

TABLE II.—*Toronto General Hospital*

Total deliveries, 12,749
126 cases with blood loss 500-700 ml. and/or signs of mild shock
Recovered within 15 minutes
2 cases with mild shock and minimum blood loss but difficult deliveries
64 cases with blood loss 700-1,000 ml. and/or signs of moderate shock
Recovered within one hour
4 cases with moderate shock and minimum blood loss but difficult deliveries
9 cases of blood loss more than 1,000 ml. and/or signs of severe shock
6 deaths up to 6½ hours post partum.

The third patient had a large baby with a labour of 44 hours and a difficult forceps delivery; death was sudden and intra partum. There was no external evidence of haemorrhage, and there was no necropsy.

The fourth patient suffered from essential hypertension; labour was induced by rupture of the membranes followed by spontaneous delivery in 12 hours, and manual removal of a retained placenta was followed by progressive shock and death in three hours. No external bleeding occurred and there was no evidence of ruptured uterus; no necropsy was done.

The fifth case was one of normal pregnancy and spontaneous delivery. Post-partum haemorrhage was treated by oxytocics (ergometrine and pituitrin) and eventually the uterus was packed. Progressive shock followed, and the patient died in 6½ hours despite repeated transfusions. There was no necropsy.

The last case was a normal pregnancy with a breech delivery. There was severe post-partum haemorrhage, treated as in the previous case but followed by death in 5 hours. At necropsy the bleeding was found to have been from the placental site and there was no uterine rupture.

*Data of Three Cases of Severe Shock with Recovery.*—The first of these was a spontaneous delivery with a severe post-partum haemorrhage but with recovery in 12 hours after transfusions. The second was a spontaneous delivery followed by inversion of the uterus and severe post-partum haemorrhage. The patient was transfused and the inversion reduced; recovery occurred in 6 hours. The third was a case of toxic accidental haemorrhage with a spontaneous delivery but severe post-partum haemorrhage. The patient was transfused, and when the haemorrhage persisted hysterectomy was carried out two hours post-partum, being followed by recovery.

#### Factors in Development of Shock

During pregnancy there is an increase in the blood volume, which is a favourable circumstance; but with delivery there is an inevitable loss of blood, which may more than overcome the increased volume of pregnancy. The great increase in the size of the uterus, full of large blood sinuses, results in an organ capable of holding a considerable volume of blood when it is relaxed; and its relaxed condition, after being emptied, provides a fertile source of haemorrhage into the uterine cavity.

Disturbance of water balance, which is usually the first indication of toxæmia, is probably evidence of increased permeability of the capillaries, and this, of course, is one of the essential factors in the mechanism of shock. Toxaemic cases with systemic oedema withstand trauma poorly.

The late toxæmias of pregnancy are accompanied by elevation of blood pressure, which may reach high levels. If convulsions supervene, and even in the absence of eclampsia, after delivery there is often a very sudden drop in pressure, which is conducive to the onset of shock. During labour the patient is subjected to various types of trauma. To this are often added sleeplessness and apprehension. There is the final mechanical trauma of delivery, which varies from a slight degree of damage to severe injury.

Immediately after delivery there is a marked lowering of intra-abdominal pressure, which probably results in dilatation of the splanchnic blood vessels. This lowering of the intra-abdominal pressure occasionally results in small bowel distension of such a degree that it may simulate paralytic ileus, and it probably renders the patient more susceptible to shock.

Let us now consider shock in connexion with the various obstetrical accidents.

#### Shock due to Obstetrical Mishaps

*Haemorrhage.*—This, the most important of the obstetrical accidents, may be the result of placenta prævia. haemorrhage may be slow and prolonged or sudden and rapid, but in either case the blood loss may be sufficient to result in shock. From clinical observation it would appear that a patient suffering from a rapid loss of a considerable amount of blood responds to therapeutic measures better than one who has lost a comparable amount over a longer period of time. In accidental haemorrhage blood loss may be equal to that from severe placenta prævia, but in many instances the shock is out of proportion to the observed blood loss. This is especially true in cases of Couvelaire uterus, or toxic utero-placental apoplexy, in which there is an infiltration of the uterine wall with blood separating muscle bundles and producing a ligneous, non-contractile uterus. To this is added the fact that practically all of the patients are suffering from a more or less severe toxæmia. In concealed accidental haemorrhage it is difficult to estimate the loss of circulating blood, especially where conservative methods of treatment are the rule, as in the hospital. It may be that the trauma to the uterine musculature is the important factor, but I believe that blood loss is more important. And, finally, there is post-partum haemorrhage of two types—haemorrhage following trauma with tearing of the birth canal, and bleeding due to failure of an atonic uterus to contract and shut off the blood sinuses. In most instances the haemorrhage is external and therefore apparent, but occasionally when it results from injury to the birth canal it may be entirely within the pelvis as a retroperitoneal haematoma, or occasionally as an intraperitoneal haemorrhage.

*Rupture of the Uterus.*—This mishap is probably the most common than is recognized clinically. It is most common through the scar of a previous section, next after difficult operative deliveries; but it sometimes occurs spontaneously even in unobstructed labours. It would appear that rupture of the uterus *per se* seldom produces clinical evidence of shock, and when the latter develops it is secondary to haemorrhage. In Eastman's series shock was present in less than half the cases of scar rupture, and in one-third of the cases of spontaneous rupture vaginal delivery was carried out without realizing that rupture had occurred. I have seen three cases of complete and one of incomplete rupture with no evidence of shock. It is obvious that if bleeding must have been slight in these instances.

*Inversion of the Uterus.*—Inversion may occur spontaneously or be due to unskillful management of the third stage of labour. A considerable number of these cases

how shock quickly. A large proportion of the remainder will subsequently go into shock either as the result of haemorrhage or from attempts at replacement, which are frequently accompanied by bleeding, often profuse. All cases of puerperal inversion of the uterus should therefore be looked upon as potential cases of shock, and prophylactic measures against this condition should be instituted once, before any attempt at its correction is carried out. Nevertheless, all cases of acute inversion do not show shock. During the past ten years we have seen even cases of acute inversion: one had profuse bleeding with severe shock; two had moderate haemorrhage and moderate shock; the other four cases had no evidence of shock.

**Eclamptic Toxaemia.**—Hailey, Schwartz, and Adair, as well as other observers, have pointed out that marked vasomotor collapse is sometimes the cause of death in eclampsia, and even in pre-eclampsia. Hunt and Adair collected eight cases in which the systolic pressure dropped by 100 to 100 mm. within a few minutes, and all of these cases showed clinical evidence of shock. Rapid delivery or deep anaesthesia may aggravate a potential case. On the other hand, it is known that hypertension cases of both sexes stand operation well. The collapse that follows delivery in cases of hypertension is probably explained by a sudden lowering of the intra-abdominal pressure with a filling of the splanchnic vessels with non-circulating blood. When death does not result quickly from the shock it may occur later from damage to the central nervous system due to cerebral anaemia. MacGillman has pointed out that during caesarean section on non-eclamptic cases there is no marked drop in blood pressure; whereas if the section was done in the case of eclampsia the fall in pressure as the uterus was emptied was frequently great—in one case 90 mm. in a period of 40 minutes.

**Psychic causes during labour** occasionally result in syncope. It is a debatable question whether such causes may produce true shock. Some observers believe that it does, and Miles Phillips thinks that emotional factors are important in the production of shock, and quotes a fatal case of Whitridge Williams's. DeLee also was of the opinion that this was sometimes a factor of importance. In Crile's theory of shock the aetiology was thought to be a combination of fear and anxiety with pain, leading to a state of mental and physical exhaustion, and eventually to shock. In any event, fatigue and starvation after prolonged labour should not be labelled "shock."

#### Management of Obstetric Shock

It is much easier to prevent the onset of shock than it is to treat the condition after it has become established. If the obstetrician has constantly in mind those conditions leading to shock, most particularly haemorrhage, he will make every effort to obviate them and to provide for their treatment before constitutional symptoms have made their appearance. In the case of haemorrhage the blood loss should be replaced as rapidly as possible, but of more importance is to try to prevent any undue bleeding. In cases suffering from hypertension delivery should never be rapid, and after delivery, if there is any marked drop in blood pressure, a tight abdominal binder should be applied, and to this may be added the weight of a sandbag. Mechanical trauma should be kept to a minimum, and when it occurs should be recognized and treated. As I have already pointed out, in all cases of inversion of the uterus anti-shock therapy should be instituted at once, even if shock has not yet developed.

In the active treatment of shock the first requisite is the abolition of pain and apprehension by the administration

of morphine. Means should be taken to retain the body heat. A temperature of 90 to 100° surrounding the body should not cause damage. In our hospital such heat is supplied in the form of warm air, thermostatically controlled by an electric heater, and no heated bottles or pads are placed in the patient's bed. The replacement of the circulating blood volume, however, is the prime essential, and any loss of time in this procedure should be avoided. In the larger hospitals to-day blood banks are usually in operation, and therefore a transfusion of blood or plasma should be available within ten minutes. Blood banks are not feasible in most of the smaller hospitals, and when these are situated at some distance from a blood bank a supply of plasma should always be on hand; to-day this is easily arranged. In cases without severe haemorrhage the plasma is of equal value with whole blood, and even when bleeding is profuse plasma is of great service. When delivery has occurred in a home, and particularly in rural districts, the obstetrician should always have facilities for the intravenous administration of glucose solution and should use it early.

Lastly, where shock has made its appearance, the trauma of any operative procedure should be avoided except where such procedure is necessary to stop active haemorrhage. In placenta praevia measures to stop the haemorrhage should be carried out while the replacement of the lost blood is going on. Indeed, when operative measures for placenta praevia are contemplated, even where there has as yet been no great blood loss, a transfusion prior to or during operation is advisable to forestall possible haemorrhage during operation. In cases of accidental haemorrhage where shock does not exist I believe a conservative method of treatment is most apt to avoid its development. In most cases of Couvelaire uterus, with the patient already in shock, the active haemorrhage has usually ceased, and any blood that appears at the vulva is that which has already poured out into the interior of the uterus. The prime requisite, therefore, is to treat the shock and not to add to it by the trauma of operative delivery. If the patient does not respond to morphine, transfusion, and heat, operation would not have saved her life; if she does respond to such measures one usually finds that the uterus has regained its contractile powers and delivery proceeds normally. Our treatment of accidental haemorrhage is conservative. Where shock does not exist there is no question in my mind that this is emphatically the best attitude. In cases of toxic accidental haemorrhage it is usually the method of choice. There may be a place for caesarean section in the treatment of toxic accidental haemorrhage, but I believe the place is small. Where severe shock does not exist and the baby is still alive and viable section may be indicated in the interest of the child, and in a few cases where fresh haemorrhage continues to occur and labour does not supervene it may be indicated after the shock has been treated.

#### Summary of Conclusions

From the clinical point of view the great majority of cases of obstetric shock are directly proportional to the amount of blood loss. This loss may be apparent or it may be concealed.

When confronted with a case of obstetric shock without obvious cause the history should be meticulously reviewed from the standpoint of possible causes of concealed bleeding, especially rupture of the uterus.

The prevention of haemorrhage is of first importance, but the replacement of lost blood is the *sine qua non* of treatment. Where haemorrhage is anticipated transfusion should be started before operative procedures are carried out.

With the first evidence of shock treatment should be started promptly before the condition has become irreversible.

In obstetric hospitals where blood banks have not yet been established supplies of plasma should be available at all times.

## BREAST-FEEDING IN ERYTHROBLASTOSIS FOETALIS\*

BY

I. A. B. CATHIE, M.D.

*Clinical Pathologist, the Hospital for Sick Children,  
Great Ormond Street, London*

Rh antibodies are frequently demonstrable in the breast milk of mothers who have borne erythroblastotic babies, and the suggestion has several times been made that the ingestion of such milk might have a deleterious effect upon the recovery of an infant whose blood cells had already been subjected to the action of maternal antibody. More recently Cappell (1946) and Davies (1947) have reported cases in which a lag in recovery in the blood state of babies with erythroblastosis foetalis was apparently overcome by weaning.

If this view is correct it should be possible to show that antibodies are not destroyed by gastric juice and that they are absorbed into the circulation. As the question of weaning or breast-feeding in these cases is of considerable importance the following investigations were undertaken to try to determine which course should be pursued.

### Investigations

The fasting gastric contents were obtained from 20 babies varying in age from 1 week to 1 year; a wide range of gastric acidity was present. Equal volumes of gastric secretion and serum with a high Rh antibody titre were incubated together. At the end of an hour's incubation at 37° C. no fall in titre was found in any case, indicating that Rh antibodies are not readily destroyed by the gastric juice.

To try to demonstrate absorption from the stomach, serum containing antibodies was fed by mouth, and blood samples were taken at intervals thereafter and tested for antibodies. In each case Rh antibody was used which had been shown previously *in vitro* to be able to agglutinate the red cells of the recipient. Absorption was tested for by the ability of the serum to agglutinate red cells of the same Rh type, and at the same time blood counts were done to check the possibility of any *in vivo* agglutination leading to anaemia. The red cells were tested for sensitization by the direct method, and in all cases the power of the serum to sensitize other Rh-positive cells was investigated by the indirect method of Coombs, Mourant, and Race (1945). These are much more sensitive methods than the ordinary tests for agglutinins, the rabbit anti-human globulin serum detecting traces of antibody when direct agglutinating techniques are completely negative.

First, an Rh-positive volunteer drank 15 oz. (426 ml.) of serum with an anti-Rh titre of 256 without any untoward results. There was no fall in the blood count, and blood taken at intervals during the next 48 hours showed no agglutinin. The cells did not become sensitized and the serum failed to sensitize other Rh-positive cells.

Next, 12 Rh-positive babies suffering from such conditions as inoperable spina bifida were fed for a complete day with high-titre serum—again with complete failure to demonstrate any antibody absorption.

Thirdly, the direct Coombs test was done daily on a baby with erythroblastosis. On the day the test became negative traces of antibody undetectable by the most sensitive methods might reasonably be assumed to have been present.

On this day and for the subsequent 24 hours only his titre serum was fed, and again no sensitization of the cells occurred and no antibody could be demonstrated.

Lest there might be some difference between the absorption of antibodies from serum and breast milk the series was completed by repeating the observations on babies with haemolytic disease but using incomplete blocking antibody. Again no evidence of absorption was found.

In these investigations complete antibody was used. The series was completed by repeating the observations on babies with haemolytic disease but using incomplete blocking antibody. Again no evidence of absorption was found.

### Comment

Infants suffering from erythroblastosis, of either icteric or haemolytic preponderance, differ widely in the severity of the disease and in their response to blood transfusion therapy. Whereas in some a single transfusion will produce a satisfactory blood level which is maintained, in others the haemolytic process appears to continue after the transfusion. Cells are no longer sensitized by agglutinin and, indeed, times when all the original cells have been demonstrated to be replaced by group O Rh-negative blood. Yet in the refractory cases there is usually a point when lysis ceases and transfused cells are maintained, and the blood count starts to rise of its own accord. In view of the failure to show any absorption of mouth-fed antibody into the infant's blood it may be that in those cases where weaning appeared to overcome a refractory anaemia the time when weaning has coincided with the time of spontaneous recovery, and that the relationship between the two is more apparent than real.

The same rather dramatic onset of blood regeneration in the more refractory cases may sometimes be observed in infants breast-fed from birth, and also in others which have been only artificially fed. This regeneration characteristically is seen in the second month of life, a time when weaning to avoid breast-milk antibodies has appeared to effect an improvement.

It is possible, as Emery (1947) suggests, that traces of antibody insufficient to be harmful may be absorbed, but if so they are not detectable by present methods. The advantages of natural over artificial foods need no elaboration, and for an erythroblastotic baby with haemolytic anaemia and a depressed marrow the disadvantages of artificial feeding should be avoided so far as is possible. It has been the practice at the Hospital for Sick Children to breast-feed such infants whenever this can be done, irrespective of the breast-milk antibody content, and the clinical progress has not suggested any relationship between milk antibodies and the duration of the haemolytic process.

### Summary and Conclusion

Investigations are described which show that Rh antibodies, although not readily destroyed in the stomach of infants, are not demonstrably absorbed into the blood stream.

It is concluded that the weaning of infants with haemolytic disease because the maternal milk contains antibodies is not justified.

I am indebted to the physicians of the Hospital for Sick Children for access to their cases, and to Mr. G. W. Cecil for technical assistance.

## RESIDUAL SUBACUTE AND CHRONIC PROSTATITIS AFTER PENICILLIN AND SULPHONAMIDE THERAPY IN ACUTE GONORRHOEA

BY

F. C. BOURGAULT DU COUDRAY

*Captain, R.A.M.C.; Graded Venereologist*

he condition I am about to describe has not, so far as I am aware, been given any prominence in the current literature. As a result of careful personal observation in Mauritius, East Africa, and Cyprus (and so presumably throughout the Tropics and sub-tropics), covering a period of 4½ years' continuous V.D. practice in the Army, I can affirm that subacute and chronic residual prostatitis after chemotherapy in acute gonorrhoea is of very widespread occurrence, and gives rise to physical signs as long as it remains untreated. Under chemotherapy I include treatment by the sulphonamides, as I consider that, from a purely therapeutic point of view, penicillin has only one advantage over the sulphonamides in gonorrhoea—that there is no evidence of penicillin resistance or "fastness" so far as the gonococcus is concerned. Hence, when the sulphonamides act favourably, they are therapeutically as effective as penicillin.

If the following are accepted as the criteria of cure in all cases of urethritis—(1) a persistently clear urine, (2) a persistently "dry" urethra, (3) a prostate which feels normal on palpation per rectum, and (4) a prostatic fluid which is macroscopically clear, and which, when fixed and stained, shows microscopically no pus cells, or at most only a few (not more than two or three in any field)—then I have found that after chemotherapy in every case of acute gonococcal urethritis return to normal is disappointingly infrequent. The departure from normality which occurs most often after treatment is the above-mentioned residual prostatitis, which fails to respond to further chemotherapy.

### Clinical Features

The signs (there are no symptoms) of such a prostatitis may be the following:

1. Persistence of slight watery mucoid, or viscous opalescent or milky mucopurulent urethral discharge, which may be manifest only in the morning, or which may occur throughout the day. Microscopical examination of such a discharge will show mucus, either amorphous or inspissated; relatively few pus cells; small squamous epithelial cells from the urethra; and no organisms, or only scanty secondary organisms, such as Gram-positive cocci or bacilli. No gonococci can be detected after penicillin.
2. Persistence of mucus in varying quantities in the urine, with finely granular epithelial debris in suspension, or coarser sinking debris or small "comma" threads.
3. A palpably diseased prostate on rectal examination. It is difficult to describe the palpable features of a normal prostate: it is much easier to describe an abnormal one. The types of abnormality encountered are threefold: abnormality of size, shape, and consistence, depending on the severity and the duration of the prostatitis when first examined. Except in well-advanced cases, however, the physical signs appear to bear little relation to chronicity. In the early stages of prostatic involvement it may be difficult or impossible to assess the condition of the prostate by palpation alone, but by constant practice minor departures from the normal can be accurately assessed.

The physical signs of prostatitis are as follows:

- (a) The whole prostate may be symmetrically enlarged—that is, both lobes are prominent with a well-marked median raphe or furrow between them. It may be boggy in consistence or it may be tense or turgid. Such turgidity, how-

ever, will yield when the prostate is massaged—that is, the lobes are comparatively soft and yield to the palpating finger when pressure is exerted upon them.

- (b) The prostate may be symmetrically enlarged and smooth but of a rubbery consistence. This stage is reached surprisingly quickly in the course of prostatic infection. In this case greater pressure is required to produce any depression in the lobes by the examining finger.

- (c) There may be unilateral enlargement. One lobe (usually the left) is enlarged and turgid or rubbery.

- (d) One or both lobes may be not only enlarged but irregular in shape and consistence—that is, nodular. The nodules are portions of the prostatic lobe which are harder than the rest. There may be only one such nodule in either lobe.

- (e) Finally, the whole prostate may be somewhat shrunken, nodular, and hard, and no amount of pressure exerted upon it by the massaging finger will produce any impression. Such prostates are very difficult to drain. As it is virtually impossible to examine histological sections of such prostates, one can only suppose that the increasing hardness is due to fibrosis.

4. A pathological excess of pus cells (polymorphonuclear leucocytes) in smears of prostatic fluid expressed by massage. It is interesting to correlate the physical signs in the prostate, ascertained by rectal palpation, with the microscopical appearance of stained smears of prostatic fluid. If this is done, a palpably diseased prostate will almost invariably contain an excess of pus cells in the prostatic fluid. The smears show pus cells in either great or moderate numbers. In the former case the macroscopical appearance of the prostatic fluid is worthy of note: it is opaque and distinctly yellow in colour. Normal prostatic secretion is semi-translucent and faintly bluish. Patients should, of course, be made to urinate immediately before prostatic massage. In chronic cases—that is, where the prostate feels hard and rubbery—prostatic smears may show pus cells in either large or small, widely separated clumps. There may also be a great admixture of mononuclear cells, which are almost certainly epithelial cells from the prostatic ducts, although they superficially resemble large lymphocytes or plasma cells. These epithelial plugs admixed with leucocytes constitute the small flocculent debris which can be seen floating in the prostatic fluid in these cases.

In my experience it is rare to find organisms of any kind microscopically in such pathological prostatic smears. Out of hundreds of such smears that I have examined microscopically I have found gonococci in only three, and secondary bacilli in about the same number. I invariably stain my prostatic smears with Loeffler's methylene blue, as not only is it a quick and clean method, but the leucocytes stand out conspicuously. Any organisms present are also easily detected, and a full staining by Gram's method may be performed subsequently if doubtful cocci are encountered.

It occasionally happens that a palpably abnormal prostate usually one of tough, rubbery consistence—will yield negative smears in which pus cells are absent or only scanty. Conversely, where a prostate feels normal a large number of leucocytes may be present in the fluid expressed from it; but by far the most constant and reliable evidence of prostatitis is the microscopical appearance of pus.

Such, then, is the clinical and microscopical picture of this condition. As it might be objected that the prostatitis in question may be the direct result of the methods employed to combat the original urethritis, or may be due to a pre-existing prostatitis, I will quote a few illustrative cases. I can affirm that the condition is discovered in the course of primary acute gonococcal infections, after penicillin therapy alone, in patients who have never had local treatment directed to the prostate or any form of mechanical or adjuvant treatment.

I was fortunate to enlist the help of Dr. R. M. Dowdeswell, a bacteriologist at the Medical Research Laboratory, when I was working at No. 87 (Nairobi) British Military Hospital, between April and June, 1946. Dr. Dowdeswell had approached me for help to enable him to carry out some

independent research of his own on the blood concentration of penicillin over a period of hours after a single subcutaneous injection of the drug, under different atmospheric temperature conditions. The sodium penicillin used in Dr. Dowdeswell's cases was dissolved in sterile doubly distilled "pyrogen-free" water, and admixed with the patient's whole blood in the proportion of 3 : 1 (three parts of penicillin solution to one part of blood). The mixture was shaken in the barrel of the syringe and allowed to stand for six minutes before being injected subcutaneously into the abdominal wall.

It is important that the condition of the prostate be ascertained, so far as possible, before commencing treatment in acute gonorrhoea. The only available method is palpation of the gland per rectum. If this is done in all cases, it will be found that the prostate is palpably abnormal in a fair proportion of them.

### Illustrative Cases

**Case 1.**—Sgt. A., admitted to 87 British Military Hospital on May 24, 1946. Exposure with European woman about twelve days before admission. Used condom, followed by prophylactic packet one hour after exposure. Appearance of urethral discharge about ten days after coitus. First infection. On examination, purulent urethral discharge. Urethral smear showed intracellular gonococci + +. Prostate felt normal per rectum. On the 27th 150,000 units penicillin injected subcutaneously. Dr. Dowdeswell, dissatisfied with the results of the blood penicillin maintenance in this case, reinjected 150,000 units on the 30th. On June 4 his urethra appeared dry. Early-morning two-glass test showed almost clear urine, no debris, in both glasses. Per rectum the left lobe of the prostate felt enlarged and slightly rubbery. On the 7th his prostate was massaged, a smear made, and prostatic fluid was collected and cultured by Dr. Dowdeswell. The prostatic smear showed pus cells + + with clumps of mononuclear cells; the culture yielded two colonies of *Staph. albus* and two of diphtheroids.

**Case 2.**—Gnr. B. History of gonorrhoea treated in India with penicillin alone, 100,000 units, on April 16, 1946. Noticed slight urethral discharge two days before admission to 87 B.M.H. on May 14, 1946. On examination, scanty, mucoid urethral discharge. An early-morning smear was sought for on the 15th, but none was found. Early-morning two-glass test showed clear urine with faint mucous cloud in suspension in both. Per rectum, lobes of prostate prominent and rather rubbery. Prostatic smear showed pus cells + +.

**Case 3.**—Cfn. C., admitted to 87 B.M.H. for penile sore on May 27, 1946. Exposure with half-caste woman ten days before admission. Used condom, followed by prophylactic packet three or four hours after coitus. Past history of syphilis in England ten years ago. He was absolutely certain that he had never had urethritis. On examination, small superficial non-durated cribriform ulcer at muco-cutaneous junction of prece. No buboes. Blood Kahn negative. Dark-ground lumination negative for *Treponema pallidum* on three occasions. On the 29th he reported a purulent urethral discharge. Urethral smear showed intracellular gonococci + +. Per rectum the prostatic lobes felt prominent, smooth, and tense. Left lobe greater than right. On the 31st 150,000 units penicillin injected subcutaneously. On June 7 his urethra appeared dry. Two-glass test showed urine clear in both glasses. On the 12th his prostate was massaged, a smear made, and prostatic fluid was cultured. The prostatic smear showed pus cells + + +; the culture yielded a few diphtheroids.

**Case 4.**—Cfn. D. Exposure on April 28, 1946, with African woman. First noticed urethral discharge on May 2. First infection. Admitted to 87 B.M.H. on May 4. On examination, viscous mucopurulent urethral discharge. Urethral smear showed gonococci + +. Per rectum the prostate felt normal. On the 5th 150,000 units penicillin injected subcutaneously. On the 9th two-glass test showed: 1st, slightly hazy with mucus and a few opaque threads in suspension; 2nd, slightly hazy with mucus. Per rectum the prostate felt normal. On the 10th he had a slight mucoid watery urethral discharge. Two-glass test

showed: 1st, very faintly hazy with mucus and a few small mucous shreds in suspension; 2nd, clear. On the 11th his early-morning two-glass test showed: 1st, clear with small mucous cloud, containing granular debris, in suspension; 2nd, clear, with small mucous cloud in suspension. He still showed a clear watery urethral discharge. On the 12th his urethra appeared dry. Urine was clear. On the 14th, reappearance of scanty mucoid urethral discharge. Two-glass test showed: 1st, almost clear, with small mucous shreds in suspension; 2nd, clear. Per rectum, slight cord-like thickening of left lobe of prostate. Prostate massaged. Prostatic smear showed pus cells + +. Prostatic fluid was cultured by Dr. Dowdeswell; culture yielded *Staph. albus*.

**Case 5.**—Cpl. E. Exposure with Seychelles girl thirteen days before admission to 87 B.M.H. on June 11, 1946. Used condom which broke. Prophylactic packet used half an hour later. Urethral discharge appeared eight days after coitus. History of gonorrhoea in Italy in August, 1945, treated with penicillin at No. 1 R.A.F. General Hospital. On examination, purulent urethral discharge. Urethral smear showed gonococci + +. Per rectum, prostate felt normal. On the 12th 150,000 units penicillin injected subcutaneously. On the 16th his urethra appeared dry. His urine was hazy with mucus and contained dense sinking threads +. Per rectum the prostate felt uniformly enlarged, smooth, and tense. On the 17th the prostate was massaged, and prostatic fluid was collected and cultured by Dr. Dowdeswell. Prostatic smear showed pus cells + + +; the culture was sterile.

**Case 6.**—Sgt. F. Exposure with African woman sixteen days before admission to Military Hospital, E.A.A.M.C., Nairobi, on July 30, 1947. Used condom, but no prophylactic packet. Urethral discharge appeared on July 27. First infection. On examination, purulent urethral discharge. Urethral smear showed intracellular gonococci + +. Per rectum the prostate felt prominent and symmetrical, with well-marked interlobar cleft. Harder than normal. On the 30th penicillin started—three-hourly intramuscular injections of 50,000 Oxford units to a total of 250,000 units. On the 31st slight purulent urethral discharge. Urethral smear showed pus and small epithelial cells and mucus only. Very scanty secondary organisms. He was given pot. cit. 15 gr. (1 g.) three-hourly in water. On Aug 3 there was a viscous opalescent urethral discharge. Two-glass test showed: 1st, opalescent with mucus, with threads and debris + +; 2nd, faintly opalescent with mucus. He was kept on pot. cit. three-hourly. On the 7th he showed slight milky mucopurulent urethral discharge. Early-morning two-glass test: 1st, opalescent with mucus and coarse sinking debris + +; 2nd, opalescent with mucus. Early-morning specimen showed pus cells and mucus only. He was then put on daily posterior irrigations with 1 in 10,000 mercury oxycyanide solution at a temperature of 120° F. (49° C.) in the irrigation can. On the 11th there was a slight viscous mucopurulent urethral discharge. Early-morning two-glass test showed: 1st, opalescent with mucus and coarse sinking debris +; 2nd, opalescent with mucus. Per rectum, prostate prominent and turgid; no induration or nodularity. Prostate was massaged, and prostatic smear showed pus cells + + +. He was kept on daily irrigations. On the 17th his urethra was dry. Early-morning two-glass test showed: 1st, faintly opalescent with mucus and coarse sinking debris +; 2nd, faintly opalescent with mucus. Prostate was again massaged, and he was discharged from hospital with instructions to report weekly for prostatic massage.

### Discussion

Such cases are so common in tropical V.D. practice that it is a wonder they have not been commented on before now. The clinical findings are above suspicion when taken in the aggregate. I have already mentioned the unreliability of digital examination alone in assessing the condition of the prostate in early cases. However, when physical signs are present in the prostate they are as definite and conclusive of disease as any time-honoured physical signs in medicine. However, the microscopical evidence of prostatitis associated with venereally contracted urethritis, past and present, is irrefutable. I have mentioned cases in which palpably pathological prostates yield negative prostatic

nears, although this is the exception rather than the rule. It is observed invariably in those cases in which the prostate is of tough, rubbery consistence. This effect may be connected with the incomplete emptying of the gland, caused by the rigidity of the prostatic stroma, for often in such cases great pressure must be exerted on the prostate before prostatic fluid appears at the meatus. It may also be due to inflammatory exudate in the stroma causing occlusion of part or parts of the prostatic tree.

The fact that the structural changes in the prostate are found, and pus is seen microscopically in the fluid expressed, at the very first massage precludes the possibility of the prostatitis being traumatic in origin. Much more ambiguous and inconclusive are the bacteriological findings, both microscopical and cultural, in this condition. I have already referred to the rarity with which organisms of any kind are detected microscopically in such pathological prostatic smears; and this seems to coincide, so far as can be judged from so small a number of investigations, with the results of culture. In the eight cases in which Dr. Dowdeswell cultured the prostatic fluid no gonococci were grown. The secondary organisms may have been contaminants.

As regards the duration of the condition, I can speak with some authority, as in Mauritius for two whole years (1943 and 1944) I had the opportunity of observing the clinical progress of these cases. Defaulting was rare, and the patients reported weekly with clockwork regularity for prostatic massage; they came with a full bladder and their urine was inspected. The prostate was then massaged with a view to draining it, and prostatic smears were examined week by week. The results of the urine test and prostatic smear were recorded in each case. I use an arbitrary scale of my own to record the number of pus cells (polymorphonuclear leucocytes) in each prostatic smear as a whole (that is, not in any one field alone), ranging from + to + + + +, so that I can record the progress from week to week.

All cases of moderate severity—those in which the prostate is not very hard, shrunken, and nodular—respond to treatment, albeit slowly. The average period required to restore such pathological prostates to normal is between two and four months. The diminution of pus cells in the prostatic fluid is extremely slow, and is not appreciable until after the seventh or eighth week, and occurs *pari passu* with the softening of the gland. The urine, however, becomes clear long before the prostatitis resolves, and all urethral discharge disappears. The condition may be regarded as cured after three consecutive negative prostatic smears.

#### Aetiology

I have no theory to advance in explanation of this condition. Certain facts, however, are known from which certain conclusions can be drawn. The cases that I have quoted demonstrate clearly that it occurs very early in the course of primary acute gonorrhoea. It is only recently that I have adopted the practice of examining the prostate per rectum before starting treatment. In the past I have invariably been presented with a *fait accompli*—a diseased prostate the origin of which was open to conjecture. Furthermore, it may appear clinically either before treatment is begun or shortly after treatment, when the gonococcus is to all intents and purposes destroyed. It is much more common than folliculitis, which occurs characteristically in untreated cases of gonorrhoea of at least three weeks' duration: or in inadequately treated cases, as with small infrequent doses of a sulphonamide. In urethritis due to chronic anterior folliculitis or litritis the urethral discharge is usually teeming with mixed organisms, and

urethral smears show myriads of secondary organisms—usually small Gram-negative bacilli—even though there may be relatively few pus cells. Occasionally also in chronic anterior folliculitis large clumps of gonococci may be seen lying close to or upon squamous epithelial cells. Such a picture never occurs in the urethral discharge associated with the prostatitis under consideration.

This early involvement of the prostate suggests that the prostatitis in question might be a purely secondary effect. The question is, Of what nature? If it be of an allergic nature, one would expect the whole of the genital tract to participate in the phenomenon. Further, if it be allergic, it is selective, not only as regards the prostate as a whole, but actually within the prostate, for it very often happens that one prostatic lobe is enlarged and tense while the other is normal in size and consistence. The same argument applies to a purely "toxic" theory. Again, a prostatitis of this nature responds, both when treated and when untreated, like any other closed infection elsewhere: when regularly drained it resolves; when untreated it leads to fibrosis. Furthermore, the severity of this type of prostatitis is definitely related to the stage at which treatment of the primary infection is begun and to previous infection. It is, indeed, to be expected theoretically, and is found in practice, much more often in cases which give a history of repeated infections, and in delayed or inadequate treatment. Again, epididymitis occurring in association with a urethritis of venereal origin is invariably preceded by a prostatitis, and gives rise to very acute symptoms, whereas the concomitant and antecedent prostatitis does not. If the prostate is palpated per rectum in cases of epididymitis, it is usually found that the prostatic lobe corresponding to the side of the affected testis is more abnormal than its fellow on the unaffected side; and prostatic smears obtained after the acute symptoms and signs of the epididymitis have subsided reveal pus cells in large numbers. Lastly, cases of prostatitis do occur in which gonococci are present in sufficiently large numbers to be detected microscopically in prostatic smears, although the history and physical signs in such cases should lead one to suspect the presence of gonococci in the prostate.

The sum total of clinical evidence, therefore, seems to indicate that the prostatitis under consideration is a true infection, due to invasion of the gland by gonococci or other organisms, or both. If that conclusion be the correct one, the following questions immediately suggest themselves: (1) Why does the posterior urethra become infected simultaneously with the anterior urethra in some cases of acute primary gonorrhoea at its very inception? (2) In those cases in which the prostate becomes infected subsequently to the administration of penicillin, why should a few gonococci survive the general and rapid destruction of the organisms which occurs, and invade the depths of the prostate, leaving the anterior urethra without evidence of infection? (3) Why is the gonococcus so difficult to recover from the prostate in cases of this kind?

#### Summary and Conclusion

The main object of this article is to stress the prevalence of symptomless subacute and chronic prostatitis discovered in the Tropics following routine treatment of acute gonorrhoea with penicillin (or the sulphonamides), in doses generally accepted as adequate, after the acute signs and symptoms of the disease have subsided. It embodies the practical experience of 4½ years' continuous V.D. practice in the Army.

Six cases have been chosen to illustrate the main features of the condition, and to prove that it can and does originate very early in the course of acute primary gonococcal infections, appearing sometimes before, and sometimes very soon after, apparently successful penicillin therapy.

The type of prostatitis encountered is described in detail, and its aetiology is discussed. No theory of its causation is advanced. Further careful and more comprehensive investigations, with the use of controls, will have to be undertaken before the problem is finally solved and a more efficient and rapid form of treatment of the condition is evolved.

I am indebted to Dr. R. M. Dowdeswell for his kind help and voluntary co-operation in what promised to be a very interesting series of investigations (I was posted outside the Command before they had progressed very far); and to Lieut. E. S. Machell, R.A.M.C., for helpful criticism and suggestions. I also wish to thank Brig. G. M. Denning, one-time D.M.S., East Africa Command, for permission to publish this article, which has been abridged from the original written at No. 87 (Nairobi) British Military Hospital in June, 1946.

## THIOPENTONE-NITROUS-OXIDE-OXYGEN ANAESTHESIA WITH CURARE FOR HEAD AND NECK SURGERY

BY

J. G. BOURNE, M.A., M.B., D.A.

*Honorary Anaesthetist to St. Thomas's Hospital*

My purpose here is to describe a way of using thiopentone ("pentothal")-gas-oxygen anaesthesia to cover the whole field of surgery of the head and neck, including ear, nose, and throat, in adult patients. The method employs curare, the passing of endotracheal tubes, and the performance of artificial respiration in patients who may be apnoeic for many minutes. The article is therefore intended only for specialists in anaesthetics who are familiar with these techniques and not for the "occasional anaesthetist," who is recommended to continue to use the better-known methods with ether.

Many anaesthetists now agree in placing thiopentone-gas-oxygen, where their use is applicable, in merit above all other agents for speed of induction, ease and safety in maintaining anaesthesia, and freedom from unpleasant sequelae. Used together, they provide light general anaesthesia suitable for surgery of skin, fascia, muscle, bone, joint, and nerve—suitable, in fact, for all operations on the limbs and the body wall. They would also cover operations in the ear, nose, and throat, on the face, scalp, and neck, and on the skull and its contents, were it not for the difficulties of intubating, packing the pharynx, and deadening the cough reflex when they alone are used.

To overcome these difficulties the common practice has been to deepen the anaesthesia with ether until the jaw and larynx are relaxed for intubating and then to continue anaesthesia with ether at a level where the cough reflex is deadened, aided perhaps by spraying the larynx with cocaine. The objections to this are threefold: (1) It is time-consuming: 15 minutes or more are usually needed to provide conditions for easy atraumatic intubation through the mouth, and attempts to intubate earlier often result in greater delay. (2) An ether anaesthesia of this depth is nearly always followed by nausea and malaise of considerable duration. (3) Under certain conditions there is a risk of explosion.

It was to eliminate these disadvantages and to gain those of the thiopentone-gas-oxygen combination that the method to be described was evolved. In this method curare replaces ether as the relaxing agent. The profound relaxation which it provides is quick and certain. The larynx and trachea can be very thoroughly "cocainized" by spraying, so that the cough reflex remains deadened, and intubating and pharyngeal packing are easy. The time taken is

greatly reduced, the patient is spared the unpleasant after-effects of ether, and no inflammable agent is used.

### Method

In outline the sequence is as follows: (a) Initial injection of thiopentone, injection of curare, injection of maintenance dose of thiopentone. (b) Insufflation of the lungs with oxygen, using the Boyle's machine and mask, for two to three minutes until the full curare effect has developed. (c) Laryngoscopy, "cocainization," intubation. (d) The machine is now connected to the tube and the gas-oxygen flow started. The larynx is packed and gas-oxygen anaesthesia continued with "assisted" respiration until spontaneous respiration has recovered to a normal depth.

Consider these points in detail. The initial dose of thiopentone varies according to the principles well understood by anaesthetists, but should be on the generous side. For a robust young adult it is 12 to 14 ml. of 5% solution. The dose of curare is 20 mg. of pure crystalline *d*-tubocurarine chloride made up in 1% solution and called "tubarine" (Burroughs Wellcome). This is given quickly in one injection immediately after the thiopentone, and as the solutions of thiopentone and curare are incompatible it is better injected through another needle into a different vein.

At first smaller doses of curare were used and found insufficient in some cases where intubating through the mouth was necessary. But if intubating through the nose is required for an operation of short duration—as, for example, dissection of the tonsils by a quick surgeon—the smaller dose of 15 mg. is preferable. Unlike thiopentone, it is difficult to predict the approximate dose of curare that is required for any individual. What is important is that it should be sufficient. With a relative overdose, artificial respiration is, by the very nature of the action of curare, extremely easy to perform. With too small a dose intubation is difficult and the merits of the method are largely lost.

The maintenance dose of thiopentone is for the purpose of providing continual basal narcosis throughout the operation. What remains in the 20-ml. syringe is usually enough. It may be given immediately after the curare or intermittently over the next few minutes according to the reaction of the patient to the initial dose. In robust young patients the whole dose is generally given at once. If the operation is a long one, further small doses of thiopentone may be added from time to time when necessary, the ankle veins being chosen as conveniently remote from the surgical field.

Insufflation of the lungs with oxygen is most simply done by holding the mask firmly on the face, turning on the oxygen bypass, and alternately squeezing the bag to inflate the lungs and lifting the mask a little to allow the expired gases to escape. This is continued for two or three minutes, when the full effect of the curare will have developed. At this stage apnoea is complete, or nearly so, but the concentration and quantity of oxygen in the lungs is high enough to provide full oxygenation of the blood, under the conditions, for many minutes.

During these minutes laryngoscopy, "cocainization," and intubation are performed with care, with ease, and without hurry. There is inevitably some accumulation of carbon dioxide. It is likely that this develops slowly, as not only is the metabolism of the patient depressed by the premedication (omnupon 1/6 gr.=11 mg.; scopolamine 1/150 gr.=0.45 mg.) and by the thiopentone but also muscle tone is abolished by the curare. In any case it is a common practice for the anaesthetist deliberately to raise the concentration of alveolar CO<sub>2</sub> in the early stages of an anaesthetic without apparent detriment to the patient.

"Cocainization" is performed by spraying the larynx, under direct vision, with the usual type of Rogers spray. The exposure is so good that there is no difficulty in directing a cloud of fine spray not only over the larynx but down the trachea. If the operation is a long one, 2% amethocaine is used liberally, but for a short operation, especially one in which blood may accumulate in the pharynx when it is finished, 10% cocaine solution is used, and sparingly.

Oral is preferred to nasal intubation whenever the surgical procedure allows, and the largest tube which will pass com-

fortably through the larynx is chosen. This is encased in a special armouring, described below. It prevents kinking, acts as a mouth-prop, and is firmly tethered by a tape tied round the neck. The wide-bore airway thus assured is desirable in all cases, and is essential to intracranial operations.

Directly the tube is in position it is connected to the machine and the flow of gas and of oxygen started. The flow-rate of gas is standard for all cases at 6 litres per minute. The flow-rate of oxygen is 2 litres per minute (giving a concentration of 25%) until spontaneous respiration has recovered to a normal depth, when it is reduced to 1½ litres per minute (giving a concentration of 20%). In the early stages it is seen from the movements of the bag on the machine that spontaneous respiration is inadequate. This is easily dealt with. The pressure on the expiratory valve is increased until, when the bag is compressed manually, the chest is seen to expand. Rhythmical manual compression of the bag is continued thus so long as it is necessary to assist respiration. This is rarely more than 10 minutes, often less than 5; occasionally compression is not necessary at all.

That the above method of dealing with the respiratory weakness is effective is shown, first, by the complete absence of cyanosis in all patients, and, secondly, by the fact that if it is performed vigorously the CO<sub>2</sub> concentration can be so lowered that temporary apnoea results.

### Apparatus

1. The ordinary Boyle's machine with standard Magill's attachment consisting of bag, tubing, expiratory valve, and face-mask.
2. Magill's endotracheal tubes, connexions, and catheter mount.
3. A flexible metal tube with bell-shaped mouthpiece (Fig. 1). This is made by Medical and Industrial Equipment, Ltd., in two

FIG. 1.—A flexible metal tube with bell-shaped mouthpiece, for use with Magill's tubes.

sizes: a No. 10, which is suitable for use with Magill's tubes of size 10, 9, and 8; and a No. 8 for Magill's tubes size 8, 7, and 6. This device effectively prevents the tubes from kinking even when they are softened by repeated boiling, which is the most satisfactory way to sterilize them. It encases the Magill's tube only as far as the base of the tongue, and has four holes near its mouth-end, through which tape is threaded and tied firmly round the neck (Fig. 2). It has been in use for many months and has proved entirely satisfactory.

FIG. 2.—The apparatus in position.

4. The Macintosh laryngoscope is preferred to other models. It sometimes happens that the Magill's tube is deflected towards the oesophagus at a tangent to its curved blade. To overcome

this little difficulty various types of simple introducers have been used to direct the tip of the tube into the glottis.

### Discussion

The merits of the method described are its speed, simplicity, and freedom from hurry; the absence of complicated apparatus and of bulky appliances near the operating field; the good relaxation; the absence of risk of explosion; and the rapidity of recovery and freedom from unpleasant symptoms.

It may be thought that there is danger in the immediate post-operative period of aspirating blood or other material owing to residual weakness from the curare and to insensitivity of the upper air-passages from the "cocainization." In practice it is generally found that both the cough reflex and the power to cough have returned by the end of the operation. The patient, however, is turned semi-prone with the head low to lessen this risk when it is present.

The surgeons on whose cases this method has been used have not reported any increased tendency to bleeding. The table is tilted 10 degrees, head up, to diminish bleeding whenever the operation allows.

Other agents are in use for procuring the initial relaxation for intubating. By some, thiopentone is used alone, while others add cyclopropane. But in my opinion there is no agent which is so quick, so certain, and so safe as curare.

## Medical Memoranda

### Bilateral Abductor Laryngeal Palsy in Syringomyelia

The under-noted case is worthy of record because it demonstrates the importance of laryngological examination in cases of nervous disease even when there is no disturbance of voice and involvement of the larynx is unsuspected.

#### RECORD OF CASE

A chaplain, aged 33, had for about seven years been aware of sensory disturbances in the hands and left leg. He noticed that when taking a hot bath the heat was not appreciated by the affected parts although temperature sensation was normal elsewhere. He paid little attention to these symptoms.

About three months previous to his present admission to hospital he had felt ill with headache and general malaise. Thinking that he had influenza, he reported to his doctor, who found that he had a temperature of 101°F. (38.3°C.), but no abnormality in throat or chest. It was then discovered that there was a large area of cellulitis over the posterior aspect of the right elbow. In a normal person this would have caused considerable pain, but, apart from the fever, the patient was unaware of its presence.

Neurological examination showed that the left leg was stiff on walking. There was marked muscular wasting of the left hand, and the grip was weak. The left eye had a small pupil and narrowed palpebral fissure (Horner's syndrome). Sensation for touch was diminished on both sides of the face and over the right side of the trunk. Appreciation of painful stimuli and of heat was lost over the chest, both arms, left side of the abdomen, and left leg. Knee- and ankle-jerks were more pronounced on the right side than on the left. Abdominal reflexes were present on both sides. An extensor plantar response was elicited on the left side. A diagnosis of syringomyelia was made.

The patient attended for rhinological examination on account of nasal obstruction and catarrh. One year previously the septum had been resected with improvement in nasal patency but little effect on the discharge. He had no complaint with regard to his voice, which in the exercise of his calling was of paramount importance to him. During the past month, however, he had noticed a tendency to become breathless on exertion.

Examination revealed a chronic infection of the right maxillary antrum, with pus in the middle meatus. There was pus in the right choana, and the posterior edge of the septum was markedly swollen. Palatal, pharyngeal, and lingual movements were normal. There was some diminution in sensation in the pharynx, but no

actual anaesthesia. Laryngoscopy showed the presence of bilateral abductor palsy. The cords, which were normal in appearance, approximated perfectly on phonation. On inspiration they barely separated, leaving a glottic chink surprisingly small to cause such slight symptoms. Deep inspiration, instead of widening the glottis, seemed rather to narrow it by sucking the cords downwards.

## COMMENT

The occurrence of bilateral abductor palsy in syringomyelia receives but scant attention in the textbooks. The fact that laryngeal palsies are caused by this condition is mentioned, but no details are given. It is evident, however, that the presence of a bilateral abductor palsy affects the prognosis in this particular case to a considerable extent. Not only does it show that the disease has extended to the bulb (syringobulbia) but there is now liability to sudden severe dyspnoea, which might demand tracheotomy.

The chronic nasal sinusitis predisposes to attacks of laryngitis with consequent narrowing of an already dangerously obstructed glottis, and the performance of tracheotomy as a precautionary measure must be seriously considered.

Glasgow.

D. BROWN KELLY, M.D., D.L.O.

## Hypertrophica Musculorum Vera

In view of the rarity of the adult type of paradoxical muscular hypertrophy it was felt that the following case might be worthy of record.

## CASE HISTORY

The patient, a youth of 19, joined a Naval training establishment in February, 1946, for the first stages of ordinary seaman's training. He first reported sick two weeks later, complaining of cramp-like pains and weakness in the muscles of the legs and thighs. These symptoms were brought on by exercise such as physical training and marching "at the double"; cramps occurred very occasionally at rest, but were always of slight severity. At first the symptoms were ascribed to the over-use of unaccustomed muscles—a not infrequent cause of muscular aches and pains in the early weeks of training. The patient persisted with his complaints, however, and was admitted to sick quarters for investigation.

On admission he gave a history of acute nephritis four years previously; there were no other illnesses. Shortly after his recovery from the nephritis he noticed pains and weaknesses in both legs, which limited the distance he could walk with comfort. At school his athletic performance was average and he achieved some notoriety by reason of his physical strength. He had had several jobs, first as a labourer, and stated that more recently he had sought lighter occupations because of his disinclination for heavy or prolonged work. He gave a family history of the death of his father and three paternal uncles before the age of 30, but unfortunately no details whatever of these cases could be obtained.

On examination he was found to be a healthy-looking youth of rather stout build and showed no abnormality of the cardiovascular or respiratory systems. Kidney function was normal. There were no abnormal signs in the nervous system, all reflexes being present, movements well co-ordinated, and all forms of sensation unimpaired. No fibrillary twitching was observed. There was marked bilateral hypertrophy of the muscles of the calves, quadriceps femoris group, glutei, and forearms. The muscles were firmer than normal in the relaxed condition, and hard on voluntary contraction. Power did not appear to be greatly lacking, though it was less than the general development would have led one to expect. Various laboratory investigations were carried out, but the only abnormal finding was creatinuria to the extent of 1.04 g. in a 24-hour specimen.

## COMMENT

This seems to be a case of hypertrophica musculorum vera. It is a very rare condition which occurs mostly in adult males, and shows muscle hypertrophy of a varying distribution, usually without perceptible nerve lesions. It differs from the commoner pseudo-hypertrophic type in having a later age incidence and also in showing an early stage of true hypertrophy with subsequent loss of power as in Spiller's (1913) cases. It was unfortunate that no detailed family history could be obtained. In Barnes's (1932) detailed report of a myopathic family there were many cases of a similar type; he found the age of onset to be mainly in the 35-40-year group, but there was a late juvenile onset in a few instances. The above case appears to be in the early stages of loss of muscle power. The condition is slowly progressive, and finally shows heroic muscular development with paradoxically reduced contractile power and fatigue endurance.

Creatine is excreted normally in the urine of infants and children of both sexes up to the age of puberty. It occurs intermittently in the urine of women, and continuously through pregnancy and the period of involution. It is absent from adult male urine except for occasional traces. Creatinuria may occur in the myopathies and in conditions of unusual breakdown of muscle tissue or increased general metabolism—for example, starvation, diabetes, exophthalmic goitre, and fever.

I am indebted to Surg. Capt. J. G. Boal, R.N., medical officer in charge of a Royal Naval sick quarters, for permission to publish this case, and to Dr. Macdonald Critchley, consultant in neurology to the Royal Navy, for his advice.

IAN L. MAXWELL, M.B., B.Ch.,  
Late Surgeon Lieutenant, R.N.V.R.

## Invaginated Meckel's Diverticulum containing a Tumour, with Associated Intussusception

New growth arising in a Meckel's diverticulum is a great rarity (Edwards, 1939) and intussusception due to invagination of a Meckel's diverticulum is an infrequent occurrence. Harkins (1933) was able to find 49 recorded cases of tumours of Meckel's diverticulum, and in a survey of 114 cases of intussusception due to invagination of the diverticulum he found a tumour present in 26. Milroy Paul (1939), recording a case, quoted 15 additional cases of invagination with intussusception, but in his case there was no tumour and he did not mention a tumour as being present in the other 15 cases. It therefore seems worth while putting on record the following case of an invaginated diverticulum containing a tumour and causing intussusception.

## CASE REPORT

An apprentice carpenter aged 16 was admitted to Llandough Hospital on March 28, 1945. He gave a history of colicky abdominal pain with attacks of vomiting over a period of about 26 hours. The bowels had been opened the day before admission, but no blood had been passed per rectum. His general condition was good, with the temperature 99.6° F. (37.55° C.) and the pulse rate 96. A small tender mass was palpable in the right iliac fossa and there was tenderness on the right side on rectal examination.

Operation was performed an hour after admission, the abdomen being opened through a McBurney incision. Free clear yellowish fluid was present in the peritoneal cavity. A mass presented in the incision and on delivery proved to be a loop of intussuscepted ileum. The intussusception, which was about 1 ft. (30 cm.) in length, was easily reduced by the usual technique, but it was then found that the apex of the intussusception had been occupied by an inverted Meckel's diverticulum. Reduction of the latter was difficult, but it was eventually accomplished. The diverticulum was found to be about 2 in. (5 cm.) in length, and at its apex was a firm mass about the size of a hazel-nut. Diverticulectomy was performed and was followed by appendectomy and closure of the abdomen. Convalescence was uneventful, and the patient was discharged from hospital 12 days later.

Microscopical examination showed that the mass in the diverticulum had the appearance of a submucous lipoma, some parts of the covering epithelium having desquamated.

I wish to express my thanks to Dr. A. E. Carragher for examining the excised specimen.

The increasing number of women pharmacists was referred to at a dinner given by the National Association of Women Pharmacists in honour of the election of Mrs. J. K. Irvine, M.B.E., as first woman president of the Pharmaceutical Society of Great Britain. Mrs. Irvine said she had met women pharmacists from ten countries, including Turkey, Palestine, and Iran, at the recent meeting of the International Pharmaceutical Federation in Zurich. Mr. H. C. Shaw, the Society's vice-president, added that in the next generation we should probably have more women pharmacists than men. He asked them therefore to take a long-range view so that the next generation of pharmacy would be better than ours.

## Reviews

### NEW ASPECTS OF PSYCHIATRY

*Dimensions of Personality.* By H. J. Eysenck, Ph.D. With foreword by Prof. Aubrey Lewis, M.D., F.R.C.P. (Pp. 308. 25s.) London: Kegan Paul, Trench, Trubner and Co. 1947.

This book contains an account of a great deal of work done by Dr. Eysenck and his collaborators in the Psychological Department at the Maudsley Hospital. Much of it was stimulated by the problems of the neurotic soldier, which predominated in wartime psychiatry. Nevertheless the chief importance of the book does not lie so much in the actual results of the investigations carried out, impressive though they are, as in the fact that we read of the fruitful introduction of new research methods into psychiatry. When two sciences which have long remained mutually isolated at last begin to influence one another, we frequently see a rapid advance owing to the methods evolved in the one field being applied to the material found in the other. This book describes such an event. The methods familiar to psychologists, which were making only slow progress in inquiries directed to normal individuals, were found to be remarkably appropriate when applied to groups of individuals who could be distinguished from one another by the success or failure of their response to actual stressors of life. The results compel us to re-examine our ideas. The basic concepts of psychiatry are largely nosological in character. "Neurosis" and "psychopathic personality," vague though these terms are, have for the psychiatrist been imbued too much with the meaning of illness. The psychological approach has focused attention on the underlying qualities of temperament, which provide the disposition to neurotic breakdown or psychopathic reaction.

The title of the book epitomizes the new viewpoint. The author teaches us to look on human beings as varying in a great number of characteristics between opposite poles of the smooth and continuous "normal curve." Differences between individuals are quantitative only, may be small or large, and are measurable. The old theories of "types," such as the "introvert" and the "extravert," have to be discarded, and the types themselves are seen as merely the extremes of the curve of distribution in respect of some one quality. The results of investigating the character of suggestibility provide an elegant and convincing illustration. Psychiatrists have identified suggestibility with hypnotizability and with the syndrome of hysteria. Patients either are or are not hysterics. Preliminary psychological investigation seemed to reveal that there was a fairly sharp cleavage between the suggestible and the non-suggestible, but further inquiry has shown this to be a statistical and experimental artefact. Most people are moderately suggestible, but they vary evenly towards the two poles. Evidence which confirms and justifies this revolution of old and accepted ideas can be drawn both from psychological experiments and from advances in clinical psychiatry during the war, and even from our knowledge of genetics. One consequence of this work will be that our textbooks of psychiatry will have to be largely rewritten.

ELIOT SLATER.

### COLOUR VISION

*Sensory Mechanisms of the Retina. With an Appendix on Electoretinography.* By Ragnar Granit, M.D. (Pp. 412; illustrated. 35s.) London: Geoffrey Cumberlege (Oxford University Press). 1947.

The study of the sensory mechanisms of vision has in the past largely depended on the interpretation of subjective phenomena. Some investigators have been at pains to attempt objective investigations, but many have been content to record their sensations qualitatively. Prof. Granit saw that more progress was likely if the subject was attacked quantitatively and objectively.

He describes in this book his investigations and relates his results to those of other workers. The first two sections form an introduction, and he discusses the results achieved by electroretinography. In Section III, which is a necessary introduction

to the following section, he considers the properties of the photosensitive substances in the retina, and then in Section IV gives a detailed account of retinal colour receptors and how he was led to discover them. The technique which he has perfected is a great advance on the single-fibre preparation in the optic nerve and enables him to study the responses of single light-sensitive units, or small groups of them, which may transmit impulses through a single nerve fibre. The nature of the experimental technique is such that the reader may wonder what has led Granit to believe that he is dealing, in a particular experiment, say, with a single light-sensitive element, or, again, in what proportion of trials a definite result is obtained. The author answers these and similar questions clearly and in a manner revealing the difficulties involved rather than merely stating the results achieved. The section on technique enables one to form an opinion of his results and instils a feeling of confidence in Granit's dominator-modulator theory and the manner in which this may be used to explain "colour vision."

The book should appeal to a variety of readers. To the worker interested in this rapidly expanding branch of physiology it provides a clear account of the results achieved. The advanced student will be interested in its account of electrophysiological methods for elucidating the mechanism of sensation. The general reader will learn of modern concepts in colour vision from chapters which do not presuppose a deep knowledge of physiology. So far, the observations on colour receptors have been made only on animals, but recent work on man by other investigators using less objective methods of experimentation suggests that modulators may exist in the human retina.

J. L. D'SILVA.

### ADVANCES IN PHYSIOLOGY

*Annual Review of Physiology.* Volume IX. Editor, Victor E. Hall; Associate Editors, Jefferson M. Crimmon and Arthur C. Giese. (Pp. 736. \$6.00 or 36s.) California: Annual Reviews Inc., and American Physiological Society. London: H. K. Lewis and Co. 1947.

The demand for annual reviews of advances in particular subjects is indicated in the preface of this volume by the announcement that a series on microbiology is to be produced. But despite the possible deviation of material and extensive cutting by the editors this volume is appreciably larger than the last, partly because papers which could not be printed during the war owing to difficulties of circulation or secrecy regulations are now available. It is almost inevitable that the articles should be of unequal merit, for authors differ in their ability to take up definite standpoints from which to survey their material, and the quality and scope of the work reviewed vary. However, this volume attains the standard of its predecessors, and for the first time since the series started it has been possible to include a significant number of articles from European authors, who give excellent reviews, as opposed to catalogues, of the subjects entrusted to them.

The book follows its usual lines and in twenty-seven articles (as against twenty-five last year) includes topics which have not been reviewed previously or for a long time—"Growth," "Physiology of Supporting Tissue," "Bioelectric Potentials in the Nervous System and in Muscle," "Defence Mechanisms"—but the majority of the articles cover a one- or two-year period to the middle of 1946. Apart from the physiologist who wishes to be sufficiently acquainted with new work to keep his subject in perspective the clinician will find much to direct him to new approaches to his problems. For instance, in the section entitled "Digestive System" H. Greengard discusses at length the aetiology and treatment of peptic ulcer, and the effects of nerve section are discussed in another article. Current opinion on the estimation of renal activity by the method of clearances is surveyed under "Kidney," and the connexion between the kidney and arterial hypertension is discussed in this and other sections. C. J. Wiggers in a comprehensive review of the peripheral circulation urges cautious appraisal of circulatory measurements made by new techniques such as atrial catheterization and discusses the haemodynamics of shock, the calculation of peripheral resistance, and the mechanism of hypertension, though a misprint occurs in the formula for calculating peripheral resistance.

It is impossible to do more than indicate some of the topics which have attracted the personal interest of the reviewer, such as the further application of electronic methods in the exploration of physiological and clinical problems as indicated by the articles on "Bioelectric Potentials" and "Electrical Activity of the Brain." W. R. Ingram and F. K. Sanders respectively discuss some of the functions of afferent nerves, both visceral and somatic, the latter author recording the latest views on hyperalgesia, causalgia, and phantom limb. D. J. Mulford describes notable advances, arising from researches intensified during the war, in our knowledge of the protein components of the blood plasma and their potential uses. An extensive review, "Muscle," considers the relationship between molecular structure and the contractile process, and mention is made of neuromuscular transmission and the possible nature of the breakdown in myasthenia.

A. HEMINGWAY.

## THE THYROID GLAND

*A Tiróide. Físio-patologia. Diagnóstico e tratamento de suas enfermidades.* By Hiló de Lacerda. Endocrinologia Elementar. Volume I. (Pp. 152; illustrated. No price given.) Brazil: Sao Paulo (Rua Rego Freitas, 490). 1946.

Those wishing to revise their knowledge of the thyroid without reading the late Mr. Cecil Joll's *magnum opus* should find this admirable little monograph useful. The author intends to produce similar volumes on the other endocrine glands. Prof. de Lacerda's conception of the "thyroidon," by analogy with the nephron and the hepaton, assists in the understanding of the normal gland, whose embryology, anatomy, and physiology he discusses in the early chapters. He then considers the pathology of the thyroid and the treatment of its diseases. It is refreshing to see adequate mention of Hashimoto's disease in such a small book, a subject completely ignored by some standard textbooks of pathology.

Perhaps of special interest to British readers will be the chapter summarizing the views of the Soviet worker Kazakov on the treatment of hyperthyroidism with hydrolysates of liver, spleen, muscle, parathyroid, pancreas, etc. Kazakov maintains that the phenomena of hyperthyroidism are those of a generalized acidosis, and that the greater incidence of the condition in the female can be explained by disturbances of the acid-base equilibrium to which that sex is subject in the premenstrual period, in menstruation, in pregnancy, and at the menopause. Kazakov summarizes the aetiology of the "functional" diseases of the thyroid thus: (a) Simple hyperthyroidism without glandular enlargement, due to increased production and reabsorption of colloid without an associated storage of excess. (b) Graves' disease, where there is not only increased reabsorption of colloid, but also its more rapid accumulation in the distended follicles of the gland. (c) In simple goitre the gland increases in size on account of lessened reabsorption of the qualitatively altered colloid and increased reserves due to breakdown of the epithelial function. (d) In myxoedema the colloid coagulates in the follicles and appears to lose the capacity for being reabsorbed via the blood stream. The epithelium therefore degenerates.

One misses any reference to the use of radio-iodine in research into thyroid function, but there is a chapter on thyroid therapy. Each chapter has a good list of references to the literature in five languages. Unfortunately the volume is very lightly bound, and there are many small typographical errors. The illustrations are adequate.

J. C. FORD.

The arrangement and style of the second edition of Wilfred Shaw's *Textbook of Midwifery* (J. and A. Churchill: 21s.) remain unchanged, but the author has added about sixty pages in expanding some sections and included new material on chemotherapy and haemolytic disease of the foetus and newborn. It remains a book difficult to appraise, for it contains a number of doctrines that have been largely disproved, some that have been approved only to a limited extent, as well as individual views of the author which command respect if not acceptance. The author discusses the details of treatment well, and the illustrations are good. Although some parts of the book will interest those who have a knowledge of midwifery, its lack of balance may detract from its suitability as a textbook for undergraduates.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*The Psychoanalytic Study of the Child.* Vol. II 1946. Edited by Anna Freud, Heinz Hartmann, M.D., et al. (Pp. 424 30s.) London: Imago Publishing Co.

In five sections: Problems of Child Development, Clinical Problems, Guidance Work, Problems of Education and Sociology, History of Child Psychiatry.

*Materia Medica for Nurses.* By A. Muir Crawford, M.D., F.R.F.P.S.G. 6th ed. (Pp. 160. 5s. 6d.) London: H. K. Lewis 1947.

A manual of materia medica intended for nurses; a new chapter on penicillin included.

*Diseases of the Chest.* By E. H. Rubin, M.D., F.A.C.P., F.C.C.P., and M. Rubin, M.D. (Pp. 720. 60s.) Philadelphia and London: W. B. Saunders Company. 1947.

A general account of chest diseases with many illustrations, including a section on the principles of surgical treatment.

*Estudios Sobre el Pulmon Colapsado.* By Dr. Jose Abello Pascual. (Pp. 506. No price.) Madrid: Publicaciones del Patronato Nacional Antituberculoso. 1946.

A monograph on collapse of lung, with clinical and experimental details.

*Penicillin Therapy.* By J. R. Goyal. 2nd ed. revised. (Pp. 177 No price.) Delhi: Dr. J. R. Goyal, the Albion Press. 1947.

An account of penicillin and streptomycin; intended principally for the medical practitioner in India.

*Old People's Welfare on Merseyside.* By Ellinor I. Black and Doris B. Read. (Pp. 110. 2s. 6d.) The University Press of Liverpool. 1947.

An account of the welfare provisions for old people on Merseyside.

*Advanced Industrial First-Aid.* By R. A. Trevethick, M.B., Ch.B. (Pp. 63. No price.) Rotherham: Henry Garnett and Co. 1947.

A pocket manual of first aid in industry intended for the layman.

*Science and Nutrition.* By A. L. Bacharach, M.A., F.R.I.C 3rd ed. (Pp. 142. 6s.) London: Watts and Co. 1947.

Recent knowledge on nutrition and dietetics described for the layman.

*Child Psychology.* By Arthur T. Jersild. Ph.D. 3rd ed. (Pp. 623 30s.) London: Staples Press. 1947.

The author describes the development of the child's mind and its relation to his behaviour.

*A Neuro-Vascular Syndrome Related to Vitamin Deficiency.* By H. Smitskamp. (Pp. 114. No price.) Amsterdam: Scheltema and Holkema's Boekhandel. 1947.

A monograph on the "burning feet" syndrome.

*Smoke: The Problem of Coal and the Atmosphere.* By Arnold Marsh, M.Sc.Tech., M.Inst.F. (Pp. 306. 21s.) London: Faber and Faber. 1947.

An account of smoke from industrial and household chimneys and its relation to health, urban amenities, and fuel wastage.

*Exposés Annuels de Biochimie Medicale.* Edited by Michel Polonovski. (Pp. 285. 560 francs.) Paris: Masson et Cie. 1947.

Includes papers on the alkaloids of ergot, bacterial antigens, synthetic oestrogens, the biochemistry of cobalt, and the initial stage in the biogenesis of organic compounds.

*Diseases of the Joints and Rheumatism.* By Kenneth Stone, D.M., M.R.C.P. (Pp. 362. 30s.) London: William Heinemann. 1947.

An introduction to rheumatic and other joint diseases for medical students and postgraduates.

*Visible Speech.* By R. K. Potter, G. A. Kopp, and H. C. Green (Pp. 441. 25s.) New York: D. Van Nostrand Company. 1947.

An account of speech sounds made visible by photographic recording; profusely illustrated.

## CHEMICAL CARCINOGENESIS

Percivall Pott began the story in the eighteenth century when he recognized that soot caused "chimney-sweeps' cancer." Clinical observation disclosed other occupational cancers attributable in the main to mineral oils and tars. In 1915 Yamagiwa and Ichikawa, in Japan, first produced cancer experimentally by painting rabbits' ears with coal tar. Soon afterwards Tsutsui extended the method to the skin of mice, with which most of the subsequent work has been done. Tar-painting yielded much valuable information about the induction of tumours, but most investigators attributed the carcinogenic power of tar to its capacity for producing "chronic irritation" of appropriate duration and intensity; only a few suspected that a specific carcinogenic constituent was present. The next big advance was made in 1932 at the Cancer Hospital in London when Kennaway and his collaborators, Cook, Hieger, and Mayneord, demonstrated the carcinogenic power of a pure substance of known chemical constitution, namely, 1:2:5:6-dibenzanthracene. The consequences were far-reaching. The use of constant pure chemicals in place of complex variable mixtures increased greatly the range and precision of experimental carcinogenesis, and, more important, chemical methods and modes of thought were henceforward increasingly assertive in cancer research. Many more carcinogenic hydrocarbons were identified, including 3:4-benzpyrene, the active constituent of tar, and 20-methylcholanthrene, a highly potent carcinogen closely related to the naturally occurring bile acids. Within the group of carcinogenic hydrocarbons there was close correlation between carcinogenic activity and chemical structure, so that the carcinogenic potency of previously unknown compounds could be predicted with remarkable accuracy. It was then a plausible hypothesis that all cancer was induced by carcinogenic hydrocarbons either introduced into the body as such or formed from normal body constituents in response to other known inciters of cancer, such as the radiations of radium, x rays, and ultra-violet light. The hypothesis in its simple form became untenable as a result of the almost alarming growth of the list of carcinogenic agents, which soon included chemical substances of the most diverse kinds. This list now includes the azo-dyes, of which "butter-yellow" is the most familiar; acetylaminofluorene, whose carcinogenic power was discovered accidentally while it was being examined as an insecticide; stilbene derivatives; and much simpler compounds such as urethane and carbon tetrachloride. The focus of interest is no longer the discovery of new carcinogens but the study of their mode of action.

Several papers in a recent issue of the *British Medical Bulletin* deal with this subject, and Prof. Alexander Haddow discusses the theoretical aspects in a paper which discloses the range and complexity of the investigations now being used in cancer research. Most medical readers may admit, without loss of face, that Prof. Haddow's erudition in chemistry, physics, and biology is beyond their reach. The enormous accumulation of uncoordinated information about cancer must be studied against a background of general biology which has vastly changed in methods and outlook during the past fifteen years. The symposium on chemical carcinogenesis by twenty contributors to the *Bulletin* is a valuable survey of modern knowledge. An introductory editorial, notable for its avoidance of the British vice of understatement, finds reason for a "hope that the daily flood of facts, which we do everything in our power to encourage, will become progressively less a mere burden to the mind and more a source of refreshment to the spirit!" Meanwhile, laymen and many doctors, excusably indifferent to the spiritual welfare of investigators, ask relentlessly: What is the cause of cancer? What are the prospects of finding a cure? The twenty contributors to the *Bulletin* cannot give a plain answer. Nor can anyone else. In truth the questions are not as plain as they seem. It is profitable to distinguish between the cause and cure of cancer in general and the aetiology and treatment of particular kinds of cancer. Most cancer research workers presume that some fundamental cell change is common to all kinds of cancer and is indeed the indispensable basis or "cause" of cancer. They disagree widely in describing this cause in terms of genes, plasmagenes, enzymes, or viruses. Knowledge of this fundamental cause may be a necessary condition for finding a true "cure" for cancer. In his admirable discussion of the chemotherapy of cancer, Prof. Haddow sets out the formidable difficulties: the host apparently exerts no protective action against its own tumour; a differential action on normal cells and their neoplastic variants is extremely difficult to achieve; and the malignant change seems to all intents and purposes permanent and irreversible. He believes that the most hopeful method of attack is the persistent investigation of the mode of action of carcinogens and that the problem of the reversal of the carcinogenic action is "very likely just soluble." This, of course, would constitute a true "cure" of cancer, but Prof. Haddow does not imply that it is within sight.

The problems of aetiology and treatment in particular kinds of cancer require a different approach. It is widely agreed that many and varied factors or inciting agents may contribute to the fundamental change which constitutes the proximate cause of cancer. These factors—"causes" in everyday usage—may be different or may operate in different combinations in the varied types of neoplastic disease. Their elucidation in human cancer may be long and tedious but is essential to rational prophylaxis. The aetiology of only a few kinds of cancer is reasonably clear; these include cancers due to radiations, the occupational cutaneous cancers induced by mineral oils and tars, and the "aniline cancers" of the bladder in dye-workers. The aetiology of most forms of human

He favours a right extraperitoneal approach through a gridiron incision under spinal anaesthesia.

Thebaut and Ward report 36 cases of thrombo-embolism. The inferior vena cava was ligated in 34; and the other 2 died on the table before the vein could be tied. All the operations were undertaken for the prevention of further embolism in cases in which it had already occurred. There was no known recurrence of embolism in any of the patients operated upon. In addition to the two patients who died on the table two others died—one five hours and one twenty minutes after the operation. The follow-up period varied from 36 months to 2 months. No oedema was seen in 19 patients; 6 patients had slight oedema after standing all day, and 2 patients had slight persistent oedema. In none was the oedema incapacitating. The authors state that it is doubtful whether the oedema is any greater than would have been anticipated if the vena caval ligation had not been performed. An interesting observation is that in 6 out of 7 cases in which lumbar sympathectomy was performed at the same time the disease intensified clinically as shown by greater pain and tenderness or increased oedema. Thebaut and Ward favour an extraperitoneal approach unless they wish to tie the ovarian veins as well or to do a bilateral lumbar sympathectomy, in which case they use the transperitoneal route. They prefer a transverse incision for the extraperitoneal operation and favour spinal anaesthesia, or general anaesthesia if hypertension is present. Heparin and dicoumarol were used post-operatively in only one case. The patient is encouraged to get up as soon as his general condition permits.

Ligation of the inferior vena cava sounds a drastic remedy, and it still occasions surprise to many that it is indeed a feasible procedure. It is fatal only if the ligation is performed above the renal veins. Ochsner and De Bakey<sup>4</sup> mention 48 successful cases performed by 27 operators, the majority being performed for septic thrombophlebitis resulting from puerperal infection; there was no evidence of subsequent circulatory disturbance in the lower limbs of these patients. Perusal of these American case reports reveals many in which death was apparently inevitable without venous ligation. If ligation is to be undertaken it seems that a good case has been made for ligation of the inferior vena cava itself. It is certain that our attitude towards thrombophlebitis must change from expectant complacency to alertness and early interference, whether it be by surgery or by the administration of anticoagulants. Moses remarks, with justification, that tense oedema extending above the knee does not occur from a simple phlebothrombosis confined below the inguinal ligament, and "it is worthy of emphasis that this clinical picture represents gross neglect, and its occurrence in a hospitalized patient is indefensible." Several years must elapse before we can accurately judge the evidence produced by surgery and by anticoagulants; in the meantime the recording of further results from individual centres is highly desirable.

### DICOUMAROL

The success of dicoumarol in the treatment of phlebothrombosis and thrombophlebitis has raised the question of its possible value in other thrombotic conditions, especially coronary thrombosis. Recent reports are favourable, and the fear that the drug might endanger life by causing or increasing subintimal coronary haemorrhage has not been substantiated. Results are difficult to judge in any given instance, but may be assessed from statistics. In Wright's<sup>5</sup> series of 76 cases the mortality rate for the treated illness

was 25% in the group of 43 selected because of repeated coronary thromboses or the occurrence of emboli, and 12% in the uncomplicated group of 33 cases. Peters, Guyther, and Brambel<sup>6</sup> found a mortality rate of 4% in 50 cases of acute myocardial infarction treated with dicoumarol, compared with 20% in 60 controls not so treated. Nichol and Page<sup>7</sup> reported similar results. These figures are said to compare favourably with those of published controls which have been quoted by Master *et al.*<sup>8</sup> as 24% to 35% for the first attack and 38% to 53% for all attacks. On the other hand they are little better than those obtained with Master's 800-calorie diet—8% and 16.5% respectively. Thus, although dicoumarol appears to be life-saving, so may be other simpler measures. In stressing the low mortality rate of 12% in the group of 33 dicoumarol-treated uncomplicated cases in their first or second attack, Wright put the anticipated death rate at 20% to 30%. This is too high. Conner,<sup>9 10</sup> for example, found the mortality was 16.2% in his unselected series of 287 cases in the first attack.

Prevention of thrombosis elsewhere and of pulmonary embolism, as noted by Wright,<sup>11</sup> may be assumed. This alone provides adequate grounds for the use of dicoumarol in coronary thrombosis, for Eppinger and Kennedy<sup>12</sup> found that pulmonary embolism was the direct cause of death in 6.5% of 200 fatal cases of coronary thrombosis and was an important contributory factor in another 17.5%. Peters *et al.* observed clinical evidence of embolism in only 2% of their 50 treated cases, compared with an incidence of 16% in 60 controls. Dicoumarol therapy must be controlled by daily estimations of prothrombin time and should continue for at least a month. The prothrombin time is kept at about one and a half times the normal value by means of daily doses of 100 to 300 mg. of dicoumarol. If the prothrombin time exceeds one and a half times the normal the drug should be temporarily discontinued. Haemorrhagic manifestations include haematuria and melaena, and may be treated with 50 to 100 mg. of vitamin K intravenously or with blood transfusion.

### ACUTE INFECTIVE DIARRHOEA AND ENCEPHALITIS

Enteritis, colitis, steatorrhoea, and many other conditions of similar type, though clinically common and as a rule easily diagnosed, are for the most part of unexplained aetiology. Infantile diarrhoea has an important place in this group of diseases which affect the intestines. Leaving aside dysenteric types of infection and those caused by contaminated milk, there still remain a number of cases of varying severity to which the name "acute infective diarrhoea" is usually applied, despite the fact that usually no infective agency is demonstrable. Amid a mass of speculation the only feature which seems to be generally accepted is that at necropsy evidence of enteritis is often surprisingly slight.

A recent paper by E. Christensen and K. Biering-Sorensen<sup>13</sup> may furnish a clue to the underlying pathology in at least some of these cases. They describe a "particularly malignant gastro-enteritis" appearing usually in epidemic form in institutions and affecting some 500 infants under 9 months of age. Clinically there was a cerebral type of vomiting, and there were marked disturbances of the water-salt metabolism. Post-mortem examination

revealed no evidence of intestinal infection, but of 32 fatal cases 8 had meningo-encephalitis, 18 meningitis without brain involvement, and 6 congestion and oedema of the brain and meninges. In two-thirds of these cases the cerebrospinal fluid showed a moderate increase in cells (type unspecified), but all cultures were negative. Duzar and Baló<sup>14</sup> had earlier demonstrated a similar meningo-encephalitis in 7 cases in a similar epidemic, and concluded that the condition was one of encephalitis lethargica. A few other cases of the same kind have been reported, about a dozen in all.

All these Copenhagen cases had a typical histological picture: congested cerebral vessels, pial infiltration with lymphocytes, perivascular round-celled infiltration, and early chromatolysis of the ganglion cells, with in one case early miliary abscess formation. Possible aetiological mechanisms are a primary encephalitis as suggested by Goldzieher,<sup>15</sup> a general virus infection with associated encephalitis, a mixed infection with a neurotropic virus, and toxæmia combined with dehydration. The two authors incline towards the theory of a virus infection with a concomitant encephalitis, though they do not exclude the possibility of a toxic encephalitis. Whatever the explanation, it is clear that we have in these cases an inflammation of the brain as opposed to a condition of simple dehydration or meningism. Further work is necessary, but if these findings can be confirmed "acute infective diarrhoea" in infants must be viewed from a new standpoint. If it can be shown that the symptomatology is wholly or in a large part due to cerebral lesions, the notable absence of post-mortem changes in the gut in this type of case will no longer be a matter for surprise and the therapeutic approach will be altered.

### EXPERIMENTAL TUBERCULOSIS

Dr. René J. Dubos, the discoverer of gramicidin, has recently been engaged on a programme of research on tuberculosis, the results of which he reviews in a recent paper<sup>16</sup> entitled "The Experimental Analysis of Tuberculous Infections." The objects defined at the outset are so fundamental that they involve an almost entirely new approach to the disease. The first aim was to devise a culture medium supporting rapid and diffuse growth and thus providing uniform material containing a high proportion of viable cells for experimental purposes. This aim has been achieved. A liquid medium has been devised in which diffuse submerged growth is obtained in a few days. The essential new constituent is a wetting agent known as "Tween 80," an ester of oleic acid, which is believed to be adsorbed on the surface of the tubercle bacillus and thus to render it dispersible in water. It is probable that this substance also facilitates absorption of nutriment; it may itself contribute to the nutrition of the organism. Such cultures retain a highly viable population for months, and form stable suspensions which can even be used for agglutination tests. The medium can be solidified with agar and used in that form for viable counts.

The animal chosen by Dubos for the study of the experimental disease is the mouse. When mice are inoculated with tubercle bacilli grown by ordinary methods a large inoculum is required to cause fatal infection, and even so the results are apt to be irregular. A small inoculum of tubercle bacilli grown in the new medium and injected intraperitoneally along with certain adjuvant substances, of which egg yolk is the most effective, regularly produces widespread infection and death in two to four weeks. This

paper makes only brief reference to other factors affecting the course of the experimental disease which have now been studied: Dubos communicated some of these results to the International Congress for Microbiology held in Copenhagen recently.<sup>17</sup> It has been found that the resistance of different strains varies greatly. Albino mice are the most resistant; C3H are also resistant to intraperitoneal injection, less so to intravenous. C57 black, on the other hand, are highly susceptible to inoculation by both routes. It seems from these findings that different strains of mice afford a fairly wide range of natural resistance within which a choice can be made according to the precise purpose of an experiment. The effect of diet on the disease was also studied; the mortality was lower in mice fed on bread and milk than in those on a diet of corn meal. Finally, the remarkable observation was made that when mice were given a minimal dose of tubercle bacilli, such as to produce only minute lesions in otherwise untreated animals, inoculation with a small dose of influenza virus three weeks later caused extensive tuberculous lesions to develop in the lungs.

Thus a single initial advance in technique has opened a new field of possibilities in the study of tuberculosis. This acute disease in mice, already shown to be capable of exact adjustment to experimental requirements and to be influenced by factors hitherto no more than conjectural, is ideally suited to studies of many kinds. It is safe to predict that the use of guinea-pigs for the assay of chemotherapeutic agents for this infection will be largely superseded. Dubos is at pains to defend this mouse infection as a suitable experimental tool, citing pneumococcal peritonitis in mice as an equally unnatural condition which has nevertheless proved useful in the same way. This defence seems scarcely necessary; the disease is, as he says, "an overwhelming haematogenous invasion of an animal possessing a fair degree of natural resistance, but no acquired immunity or hypersensitiveness." This being so, it is not far removed from the more acute forms of tuberculosis in man.

### PROTEIN ANALOGUES BY SYNTHESIS

Woodward and Schramm have reported a reaction that produces linear high polymers of amino-acids in peptide linkage.<sup>18</sup> The reaction is not new, but its implications were not appreciated by the German workers who first stumbled on it forty years ago. The type of monomer used is an inner anhydride of the N-carboxy derivative of an amino-acid. Polymerization can be initiated by, for example, the trace of water present in reagent benzene used as solvent. The reaction can be pictured as proceeding by the addition of water to yield the labile N-carboxy amino-acid, which then couples with another molecule to form a dipeptide, with loss of CO<sub>2</sub> and H<sub>2</sub>O; the latter catalyses further reaction, leading either to lengthening of the chain or to the start of a new chain.

On standing for several days the solution becomes increasingly viscous; on evaporation it can be made to yield films or threads of "synthetic protein." A product made by co-polymerization of *l*-leucine and *dl*-phenylalanine in this way had a molecular weight of the order of 5 million, corresponding with at least 10,000 amino-acid units. The product is a protein only in the sense that it is composed

solely of amino-acids, linked as in proteins. By copolymerization of mixtures of their carboxy anhydrides, amino-acids could doubtless be linked together in any desired number and proportion, but there is no likelihood that the order of linkage could be controlled so as to imitate any particular protein, even if we knew the correct order. Nor could the chain length be accurately fixed, though some control might be exercised by varying the concentrations of starting materials and catalyst.

There thus appears little justification for the sweeping suggestions in the American press that this discovery may provide the means of producing new synthetic antibiotics or of modifying the infectiveness of viruses by altering at will the size and structure of protein molecules. Also any fibres or films produced in this way would need to have outstanding advantages over existing natural and synthetic textiles and plastics to justify the high cost of the raw materials. Of great theoretical interest is the fact that these complex compounds of high molecular weight, similar in many chemical features and physical properties to natural proteins, can be built up from molecules that are not only relatively simple in structure but may even be synthesized themselves from materials of no more "vital" origin than ordinary coal-tar intermediates and other primary reagents of organic chemistry. True, the amino-acids thus made in the laboratory lack one characteristic, indeed unique, feature of the naturally occurring compounds. They are all optically inactive, consisting of equimolecular parts of the natural and unnatural isomers. Consequently any of Woodward's compounds made entirely from synthetic materials—unless these are first "resolved"—will have no action on the plane of polarized light. With this limitation, however, and all that it may involve in more purely biological behaviour, Woodward's researches may still be legitimately regarded as an important extension of the discovery, more than a century ago, that urea, previously regarded as a typical product of the living animal organism and beyond the synthetic power or scope of the chemist, could be made from such inorganic substances as ammonia and carbon dioxide.

That discovery, still generally attributed to Wöhler, marked an epoch in chemistry and biology; it was the essential step that led to the birth of biochemistry. Woodward's work is technically a much more complex achievement and perhaps even a more brilliant one. However unlikely its immediate industrial or medical applications, it is certainly worthy of attention, if only to dispel the suspicions that may have been aroused by some jaunty extrapolations in the American press.

### PROTEIN METABOLISM IN INFANTS

In recent years there has been an increasing use of special digests of protein for the feeding of premature and sick infants, and with this has come a re-examination of various aspects of protein metabolism. Prof. Emmett Holt and his co-workers in Baltimore and later in New York, first in rats and in adults and later in infants, have started some important and fundamental studies in this subject, some details of which are now available.<sup>1</sup> The testing of the nutritional quality of some available milk preparations in the normal infant has been carried out by careful metabolic studies in three normal full-time male babies. Four types of diet were used: an evaporated milk mixture, a mixture based on an enzymatic digest of casein, a similar digest of lactalbumin, and an acid digest of casein supplemented with

tryptophan and cystine. All the four diets were given in five daily feeds on a basis of about 100 calories per kilogram, supplemented with ascorbic acid and "oleum percomorphum." Brewer's yeast was added to supply the vitamins of the B complex. Each batch of the diet mixture was assayed for its nitrogen content and the daily nitrogen intake of the subjects calculated for the seven-day period of the test. Each infant received the four diets for consecutive periods, and from the urine, faeces, and blood elaborate estimations were made of the nitrogen output, haemoglobin, total plasma proteins, albumin, globulin, non-protein nitrogen in the blood and in the urine, amino-acids, urea, and other substances. In summary the nitrogen retention and weight gain of the three infants while on the acid digest of casein mixture were respectively about 30 and 50% lower than those obtained when the same subjects were given synthetic diets based on enzymatic digests of casein or lactalbumin. Fluid, calorie, and nitrogen intake were essentially the same with all the diets. The biological value of these two enzymatic digests was about the same as that of the evaporated milk mixture used as the fourth test material. It is suggested that the acid digest of casein lacks certain peptide-like substances ("strepogenin") occurring in the enzyme digests and that the strepogenin fraction is required for the maximal utilization of amino-acids in the diet.

These broad studies, so to speak, are followed by a detailed investigation of tryptophan requirements in the infant, conducted on three healthy male infants in much the same manner as the previous study. A tryptophan-deficient diet was used—an acid hydrolysate of casein—and as control a similar diet with a tryptophan supplement added step-wise to supply 0.5, 1.0, and 1.5% of the protein content. Cystine was added to all four diets and brewer's yeast again as a source of B-complex vitamins, together with ascorbic acid and oleum percomorphum. The measurements of intake and output were conducted as already described. In all three subjects on the tryptophan-deficient diet there was a marked decrease in the daily weight gain and a drop in nitrogen retention—equivalent to a negative nitrogen balance in the fully grown adult. Within ten days a tryptophan-poor diet caused an appreciable fall in the blood protein level chiefly reflected in the albumin content. In one subject the plasma proteins returned to nearly normal levels on the diet with the 0.5% added tryptophan, whereas it required the 1.0% addition to restore nitrogen retention, weight, and urinary tryptophan to normal, which suggests that blood proteins have a claim on the available nutrients prior to those of other tissues. Urinary studies suggested that the tryptophan level of the urine may serve as a useful criterion for the estimation of the minimum dietary requirements of this amino-acid. Previous studies on adults had suggested that the tryptophan requirement of an adult was about 6 mg. per kg. of body weight. The present work puts the level for infants between 5 and 12 months of age at about 30 mg. per kg. of body weight for normal growth, and this explains in part the high protein needs of the growing infant. Another difference from conditions in adults is that even after 6 weeks' tryptophan-deficient diet there was no change in the level of plasma proteins. An interesting point was a severe anorexia on the tryptophan-deficient diets in the three infants; it was not caused by taste.

The Bradshaw Lecture will be delivered by Dr. Janet Vaughan, F.R.C.P., before the Royal College of Physicians of London (Pall Mall East, S.W.) on Thursday, Nov. 6, at 5 p.m. Her subject is "The Anaemia Associated with Trauma and Sepsis."

## UGANDA JUBILEE

INTERTERRITORIAL MEETING OF THE EAST AFRICAN  
BRANCHES OF THE B.M.A.

This meeting, which was held in honour of the fiftieth anniversary of the arrival in Uganda of Sir Albert Cook, was opened at Kampala on Sept. 3 by H.E. the Governor of Uganda, Sir John Hathorn Hall. Dr. A. J. Boase, president of the Uganda Branch, gave the presidential address, in which he outlined the history of the British Medical Association in East Africa and paid tribute to Sir Albert Cook. He also welcomed to the meeting Mr. J. L. Gilks, who brought the good wishes of the Council of the B.M.A. The meeting was also attended by delegates from Kenya, the Sudan, Tanganyika, and the Belgian Congo. One of the outstanding addresses was that by Sir Albert Cook, himself, on the history of Mengo Hospital, which was the subject of a special article in our issue of Aug. 30 (p. 342). A copy of this issue of the *Journal*, published only four days before the meeting, was sent by air mail to Kampala for the occasion, and was then exhibited with a collection of photographs, books, and records dealing with the early days at Mengo Hospital.

## Health of Africa

Dr. A. R. Patterson spoke on the "Health of Africa," drawing attention to the twin evils of over-population and loss of soil fertility, problems which would demand the closest attention in the near future in East Africa. He suggested that now was the proper time for a Royal Commission to study the whole matter. A paper on syphilis in Africans was read by Dr. Bali in the absence of the author, Dr. J. de Mello, of Nairobi. The author believed that there had been a big increase in the incidence of syphilis in Nairobi, both in the town and in the reserves, since 1939, particularly among domestic servants. After describing the clinical findings in Africans, he called for a greater measure of control of the disease and of supervision of those affected.

Dr. H. M. Woodman, of Juba, speaking on filariasis in the Southern Sudan, pointed out that in this area all forms of filariasis existed and the incidence of the disease was high, but there were many puzzling features. The insect vectors of filariasis found elsewhere to be important were either rarely found or, if found, were not important in the Sudan, and he concluded that the insect vectors responsible in this region were still unknown.

Dr. J. A. Carman, of Nairobi, read a paper on the use of curare in anaesthesia. Then Dr. R. B. Baird described his researches into the causes of tropical pyomyositis. The condition was such a common cause of invalidism that its prevention was a matter of great economic importance. Dr. Sanade then described his experiences with cases of blackwater fever.

On the Friday morning the meeting heard an account by Dr. J. N. P. Davies of a form of heart disease common at Mulago but hitherto undescribed in East Africa. After inspection of the photographs and specimens, delegates agreed that this endocardial necrosis and fibrosis was a novel and obscure condition; it was asserted that it did not occur in Nairobi. A large audience listened to a paper by Dr. Frank Hawking, Joint Secretary of the Colonial Medical Research Council, who dealt with recent advances in the chemotherapy of tropical diseases—penicillin and streptomycin, and the new sulphonamides—and then made a survey of the newer drugs available for many tropical infections. This authoritative review led to a deluge of questions, to which the speaker replied until he had to be rescued by the President, and the Conference was moved on to drink coffee and to subject Dr. Hawking to more intimate questioning.

Later the meeting divided into two sections. The Surgical Section heard a paper by Mr. D. Burkitt on the treatment of hydrocele, while at the Medical Section Dr. P. Hutton and Dr. A. Raper opened a discussion on tuberculosis in the African. It was pointed out that the results of treatment were very poor. Most infections were primary infections and the African had no initial resistance and did not develop any. The infections were acute and the mortality heavy. Few Africans responded to treatment, and so the only hope of avoiding a grave problem as Africa became industrialized was to search for some method of building up African immunity. With the advent of B.C.G.

vaccine and the "vole bacillus" vaccine, a possibility had arisen that immunity could be built up without a great wastage of African lives. Mr. I. W. J. McAdam and Dr. Billington opened a discussion on tropical ulcer. Mr. McAdam showed a number of cases treated by penicillin and skin grafts. Dr. Charters described the effects of different diets upon these ulcers in Somali and other soldiers living under identical conditions in the Army.

Finally a business meeting of the East African Branches was held, and is reported briefly in this week's *Supplement* at p. 98. Afterwards the delegates were entertained at the Sisters' Mess, Mulago. In the evening most of the delegates and their guest, the Hon. C. L. Mortimer, Member for Health and Local Government in Kenya, dined at the Imperial Hotel. Most of the visitors to Uganda left on the Saturday, and so ended this tribute paid by his colleagues to the doyen of the profession in East Africa—Sir Albert Cook.

## THE WORLD HEALTH ORGANIZATION

The foundations of the World Health Organization are being well and rapidly laid. It will be recalled that the organization, which is one of several specialized agencies forming part of United Nations, was established after an international conference in New York in the summer of 1946. Its structure and functions were described in this *Journal* by Dr. Melville Mackenzie (Sept. 21, 1946, p. 428), United Kingdom delegate to the conference and a member of the Interim Commission, a body charged with the preparatory work of the Organization. Towards the end of last year the staff of the Health Section of the League of Nations was taken over by the Interim Commission: at the beginning of the present year the functions of the Epidemiological Intelligence Department of the Office International d'Hygiène Publique were transferred, and also the health activities of Unrra, and negotiations were proceeding for the incorporation of the Pan-American Sanitary Organization.

Liaison has been established with the several other specialized agencies of United Nations concerned with public health. These are the International Labour Organization, originally founded in 1919 by the Treaty of Versailles; Unesco, established in 1945; the Food and Agriculture Organization, set up in the same year for the purpose of raising standards of nutrition in all countries; and, the latest of these agencies, the International Civil Aviation Organization, which will be concerned, among other matters, with the certification of inoculation and vaccination of air passengers and crews. Other organizations of United Nations which have activities related at some point to W.H.O. are five of the principal commissions—namely, those concerned with statistics, changes of population, narcotic drugs (the successor of the old Fifth Committee of the League of Nations), social questions, and transport and communications. Joint committees have been set up with certain of these agencies. Thus a nutrition committee will advise both W.H.O. and F.A.O., and it is proposed to have two joint technical commissions of W.H.O. and I.L.O., one to concern itself with industrial hygiene and the other with the provision of medical care. Certain non-governmental agencies, such as the international unions against tuberculosis, cancer, and venereal disease, have wanted to establish relations with W.H.O., but the Interim Commission has felt that such arrangements should be deferred for the agenda of the first assembly.

A matter which brooks no delay is epidemiology and quarantine. A committee for this purpose has been set up under the chairmanship of Dr. Melville Mackenzie. The problems arising out of the application of existing sanitary conventions and the value of the methods used for collecting and disseminating epidemiological information are being examined. An expert subcommittee on malaria has been set up as well as another on yellow fever, and a small body of experts has been appointed to form the nucleus of a future committee on biological standards. Proposals to consider the setting up of a tropical diseases institute and the formulation of an international programme for combating venereal diseases have been deferred for the time being, and another matter remitted to the agenda of the assembly is a proposal to undertake a comparative study of central public health services in various countries and of the resources at present available in such countries for training

medical and other staff essential for public health services. Another technical committee has been appointed to consider the international list of causes of death and the establishment of a list of causes of morbidity. Finally, a committee of five experts technically qualified in the pharmacological and clinical aspects of drug addiction has been established to advise on technical questions concerning habit-forming drugs.

A committee, with representatives of Canada, Egypt, Mexico, India, and Norway, has been considering the question of a permanent headquarters for W.H.O. There are many considerations: the privileges which would be granted by the host State, the internationalization of the site, its accessibility to the world at large, climatic considerations, and the general use by the local population of one of the working languages of United Nations. Various Governments have been asked to state their views. From the point of view of accessibility (14 hours from London by air), language, and position, almost at the junction of three continents, there is something to be said for Cairo. In the western hemisphere some advantages might be claimed for New Orleans. On the other hand, Geneva has the international tradition, for eighty years the centre of the International Red Cross and for twenty years the home of the Health Organization and the I.L.O. But the final selection may be none of these.

## Preparations and Appliances

### APPARATUS FOR LIFTING PATIENTS

Dr. J. GUBBINS, Clonmel, Eire, writes: In these days of shortage of nursing staff a description of the following apparatus for turning and lifting a helpless patient should be of great interest to the medical and nursing professions.

A is a handle to wind up and down by means of belts that pass over rollers at B which are adjustable to move up and down the bed. The belts pass to and are fastened to a bar at C, to which the rollers D are attached. Over D pass two slings of appropriate length and width which after being passed under the patient are buckled at H. The whole may be lifted by

turning handle A. By gently pulling the slings E the patient may be easily turned over. The height and width of the stand are suitable for a standard hospital bed, and by means of the wheels F the apparatus may be moved to any desired position. A brake screw, G, keeps the stand steady.

I can vouch for the efficiency of the apparatus, having originally designed it and used it as a patient for six months. Mr. C. Cullen, engineer, of Langford, Bristol, made the original machine, and greatly improved my own rather crude idea. Two models are now in use at Winford Orthopaedic Hospital, and the staff there tell me they are invaluable. One nurse can lift and turn a patient, whereas before the apparatus was used three nurses at least were required.

## Reports of Societies

### POST-OPERATIVE THROMBOSIS

A discussion on post-operative thrombosis was held in the Section of Obstetrics of the Royal Society of Medicine on Oct. 17, Mr. A. J. McNair presiding.

#### Chemical and Mechanical Factors

Dr. HELEN PAYLING WRIGHT said that pulmonary embolism had been estimated to follow in one out of every hundred major operations, and about one case in six was fatal. The incidence of thrombosis was almost twice as great in females as in males, and most frequent after operations in which the abdominal cavity was opened and the pelvic viscera explored. The main changes during the post-operative period were a rise in the fibrinogen content of plasma and increased activity of prothrombins. Fibrinogen was shown to undergo diminution in concentration immediately after operation, and subsequently to increase by the third or fourth day to nearly double the pre-operative value. Estimation of fibrinogen B, an intermediate substance produced by conversion of fibrinogen to fibrin, if taken in conjunction with the prothrombin time and the temperature, would, it had been suggested, give a reliable prognosis. She was not convinced, however, that a great increase in the fibrinogen B fraction in the post-operative phase was pathognomonic of incipient thrombosis; she had found that following operation or delivery the fibrinogen content of the plasma increased in all patients. Prothrombin estimations also showed increased activity even in the absence of any clinical or demonstrable thrombosis. It seemed likely that these changes occurred invariably in the post-operative period. As for the remaining criterion, the temperature, it was well known that urinary or chest complications, or even lactation, might cause an unexpected rise. The only safe course was to rely on clinical observation of the patient in the post-operative or puerperal period.

The part played by blood-platelets in initiating thrombi in injured blood vessels was well recognized. These elements increased after operation or parturition; usually the increase became apparent on the fifth or sixth day and reached a maximum about the tenth day. The increase in the platelet count was correlated with the severity of the operation. The more extensive the tissue damage the greater the platelet response. She had observed a further change in platelets in this phase, namely, a greater adhesiveness, at a maximum again at about the tenth day. It appeared that the young cells which had entered the circulation in response to the stimulus of the trauma were responsible for this change.

The importance of venous stasis was first stressed almost a century ago. It was now recognized that the thrombotic process usually started in the small plantar and calf veins, not in the femoral vein itself. Formerly anatomists thought that Poupert's ligament played an important part in thrombosis by causing constriction of the vein at the pelvic brim. Dr. Wright here related some experimental work she had carried out which pointed to the likelihood of some constriction at that point, causing the appearance of small emboli. Radio-active sodium<sup>24</sup> was injected into the foot in a subject known to have severe varicose veins. At the end of a minute no radio-active substance was reaching the counter over the groin; at that moment, however, the subject flexed his foot dorsally, and within two seconds a shower of gamma rays was recorded in the femoral vein. Evidently the blood had been held up, and a slight movement was sufficient to move it along at a much increased rate. The importance of supervised exercises and early ambulation must be emphasized in the prevention of thrombus formation in the post-operative and parturient phase.

#### Morbid Anatomy and Some Clinical Indications

Dr. MAGNUS HAINES said that it should be remembered, first, that thrombosis was often symptomless and without physical signs; secondly, that the time of onset was variable; and, thirdly, that most of the patients were over 40 years of age. It was held by some that nearly all fatal emboli occurred in

cases of unsuspected thrombosis. The mechanism by which the thrombus became separated was another problem. In some cases small pieces of the proximal end of the thrombus were detached; in others the embolus was 40 or 50 cm. in length.

Records of cases of post-operative thrombosis were scanty. There was no difficulty in keeping a record of the fatal cases, but the same should be done with patients who recovered. Dr. Haines then reviewed the operations for the period 1927-46 at the Chelsea Hospital for Women. They numbered 30,000, and among them there had been 55 cases of fatal pulmonary embolism. The abdominal operations numbered over 11,000, with 43 fatal cases of pulmonary embolism. The series could be divided into two periods, the beginning of the second period coinciding with the establishment of a regime of post-operative physiotherapy. The mortality from pulmonary embolism fell considerably during the second period, but the fall, roughly speaking, was of the same general order as the fall in the death rate from other causes, so that the physiotherapy did not appear to have made a significant difference. With few exceptions these figures related to a period unaffected by the use of any form of anticoagulant. It would be interesting to report on the next ten-year survey, when a greater reduction in mortality might be expected as a result of the use of these substances.

### Surgical Precautions

Mr. A. DICKSON WRIGHT said that the occurrence of thrombosis and embolism after operation or childbirth was freakish and variable. It varied from country to country, from hospital to hospital, even from ward to ward. In German hospitals they were very "thrombosis-conscious." He remembered seeing posted on the walls of a Charlottenburg hospital, "Breathe deep, spit hard, and wave your hands in the air." Nature, by causing the blood to clot, "has prevented us from dying from haemorrhage, only to enable us to die from thrombosis." Any disease with a 30% mortality demanded the greatest exertions on the part of those looking after the patient. Apart from haematological factors, certain mechanical factors were involved, of which Fowler's position was the chief. It caused venous stagnation of the legs and pelvis, and it had been shown to be of little advantage for peritonitis, for which it was invented; it should be abandoned. It was good for the patient to sit up in bed, but he should lie down flat at night and for the afternoon siesta, and be encouraged to lie on his side. Early ambulation was now expected and enjoyed by the public and by the nurses, except for a few die-hards. In some cases in America, he believed, the patients were walked off the operation table. Early ambulation was not possible, however, with catgut suture of the abdominal wall. Bleeding should be minimized, for with the shedding of blood the risks of thrombosis were greatly increased, as also in miscarriages and in post-partum haemorrhage. It was a bad custom to put the patient to bed for some days before operation. A dangerous case from the point of view of thrombosis was one which had been treated in bed by the clinician for a long time unsuccessfully and then handed over to the surgeon. Such a patient should be got up and walked round a little. If the patient had to be kept in bed long after operation some deep breathing and muscle-twitching must be carried out. The patient with a history of thrombosis, personal or family, required most careful consideration. No intravenous anaesthesia or pyelography should be carried out in such a case. It was worth while tying both femoral veins as part of the operation itself. Figures from a Boston clinic in which in some 400 cases the vein had been tied as a routine and in another 400 had not been tied showed a reduction of all post-operative venous trouble in the first group as compared with the second. There was an idea that after childbirth only the classical "white leg" was seen; this was not so at all, the whole gamut of manifestations of thrombosis had been observed. In a ward in the North-Western Fever Hospital, where twelve women were suffering from puerperal thrombosis, all the different types were seen.

### First Signs of Thrombosis

Very often (Mr. Dickson Wright went on) pulmonary embolism was the first sign that thrombosis was taking place. It was a good thing to regard every case of pleurisy after operation

as due to a pulmonary embolism. Frequently these were regarded as cases of simple pleurisy and attributed to post-operative chills, cold corridors, and so forth. One specimen of blood-stained sputum during the twenty-four hours after operation clinched the diagnosis of embolism. A stitch-like pain in the ribs after operation was another indication. Thrombosis of varicose veins after operation and of the normal superficial veins was a worrying complication; it showed that the patient was "in a mood to thrombose." Careful examination was called for in such cases, and he would ligate the common femoral vein on the affected side. Iliac thrombosis was of special interest to the gynaecological surgeon. The condition was treated by lumbar ganglionic block.

Mr. Dickson Wright pleaded for the prompt use of heparin, big doses of which should be given immediately and continued for two or three days until dicoumarol, started at the same time, could take over the anticoagulant action. He had used a great deal of dicoumarol, and had had no mishaps at all. It was a most valuable drug.

In conclusion, he said the price of freedom from post-operative thrombosis was unrelaxing vigilance. Signs must be looked for in the calves of the legs, under the ribs, and in the temperature chart. All surgeons had experienced the vindictiveness of relatives after a death from embolism. They would not listen to the "bad luck" story at all, and from now on, with anticoagulants available, they were likely to show less mercy, and might even exact retribution for precautions left untaken.

### Gynaecological Considerations

Mr. LESLIE WILLIAMS said that gynaecologists in the past had had a bad reputation for cases of post-operative thrombosis, but he did not think they deserved it any more than the general surgeon. The basis of modern treatment was that these thrombi practically always started peripherally, in the small deep veins of the calf, not in the iliac veins, as they rather tended to think. Active movements were valuable. Sir William Fletcher Shaw had described two wards in different hospitals, under the care of the same gynaecologist, admitting the same type of patient, and in which the same pre-operative and post-operative treatment was carried out except that in the one hospital systematically graduated post-operative exercises were given, and not in the other. In 1,635 consecutive operations followed by graduated exercises the incidence of fatal embolism was 0.06%, and in 3,618 operations not so followed it was 0.30%, or five times as great. Some cases even of sudden and severe pulmonary embolism could be saved if large doses of heparin were given immediately. In this country the quantities given were not large enough. They talked of 5,000 units, but this was only 50 mg. and utterly inadequate. A dose of 125 mg. should be given immediately intravenously, followed by doses of 100 mg. every four or five hours, until such time as dicoumarol, given simultaneously, took effect. The ligation of the femoral vein on both sides following the discovery of venous thrombosis seemed to him a bit of "blood and iron surgery," and he could not bring himself to like that idea at all. Paravertebral sympathetic block, on the other hand, was a treatment to which he gave almost unqualified praise.

Dr. KENNETH BALL described the measures taken in a Middlesex county hospital. A combination of heparin and dicoumarol was used, heparin being given by intravenous drip for from 48 to 72 hours. In puerperal cases a total dose of 60,000 international units of heparin was given in the course of 50 hours. He gave some figures comparing an earlier series of cases treated conservatively, with complete immobilization, with a later series treated with anticoagulants. His inference from the figures was that the present treatment had shortened the stay of these patients in hospital to three weeks and their confinement in bed to one week.

Dr. JOHN HOWKINS considered the Trendelenburg position the prime offender. The position was essential in gynaecological operations, but a generous sorbo rubber pillow should be provided, and some means of support should be given to the ossa innominata by a clamp which held the patient up by the pelvis. A type of clot not mentioned was that which originated at the site of operation; it was particularly liable to occur in operations on a septic site. More thrombosis, in his experience, followed subtotal than total hysterectomy; whether the

stump provided a sort of "locus of clottery" he could not say. In necropsies he had noticed that the clot did not occupy the whole of the lumen; what killed the patient was not the clot but the immense spasm which the clot evoked. Fowler's position was out of the question. The patient should be allowed to lie in the position in which she was most comfortable.

Dr. V. B. GREEN-ARMYTAGE mentioned the absence of embolism following the Fothergill operation. He also drew attention to the earliest and most dramatic description of the condition (Numbers v. 21-2). Mr. McKIM McCULLAGH spoke of the importance of good theatre work in avoiding disaster. In their replies Mr. DICKSON WRIGHT reaffirmed his contention that it did no harm to tie the femoral veins, and Dr. HELEN PAYLING WRIGHT expressed an emphatic view that the fundamental cause of thrombosis was still unknown.

### ACUTE POLIOMYELITIS

At a meeting of the Section of Epidemiology of the Royal Society of Medicine on Oct. 6 Mr. K. I. NISSEN reported on the outbreak of poliomyelitis on St. Helena in 1945-6. It was preceded by an epidemic of influenza of the usual seasonal type. In the population of under 5,000 there were 11 deaths, 66 paralytic cases, and 142 abortive or non-paralytic cases. Most of the latter were so ill for a few days that they had to be admitted to hospital.

Two special clinical features were recorded: the dorsum of the tongue was not furred but was bluish-grey in colour, whereas the margins showed bright red papillae; the odour of the stools was extremely pungent. Only 4% of the cases were children under 5. The small European population, the garrison, and the island recruits appeared to be immune. It was thought that this fact, together with the relative immunity of young children, might have been due to a higher vitamin-C intake, but the evidence on this point was inconclusive.

Dr. L. J. M. LAURENT gave an account of 13 patients admitted to the Park Hospital in the summer of 1946 who all had aseptic lymphocytic meningitis; some had encephalitic symptoms, and one died in coma. All the others had recovered without paralysis or other sequelae. None had been in contact with cases of poliomyelitis. All attempts at isolating a virus from the cerebrospinal fluid, and from the nervous system of the fatal case, by animal inoculations had been unsuccessful. The aetiology was undecided. During the present outbreak of poliomyelitis a number of similar cases had been admitted, and they were all assumed to be due to the virus of that disease.

Dr. DOUGLAS MCALPINE said that the number of cases of poliomyelitis and polio-encephalitis notified this year up to the present time exceeded 6,500; the corrected figure was probably less than two-thirds of this total. It had become increasingly clear that cases occurred all the year round—an important epidemiological point. A preliminary estimate from the Ministry of Health suggested that at least 20% of all notifications had been over the age of 15—a fact which confirmed the upward trend in the age incidence in other countries. The mortality figure had been low—probably below 10%. The symptoms which should suggest an abortive attack in contacts were headache, shivering, malaise, vague body pains, and fever. To all or some of these might be added catarrhal symptoms (sore throat, coryza) or gastro-intestinal symptoms (nausea, vomiting, diarrhoea). Polio-encephalitis had been relatively common earlier in the outbreak. Nystagmus was the commonest sign of polio-encephalitis. An unusual degree of drowsiness and mental confusion was noted in many cases. An extremely rare and unusual type of cerebellar picture had been seen in some cases, consisting of emotional instability, gross ocular tremor, and tremor of the head and limbs. Two unusual findings in the C.S.F. had been noted, together or independently: a relatively normal or normal cell count and a marked increase in the protein content of the fluid. An unusual form of meningo-encephalitis which occurred in 1946, reported by Jennings, and described at this meeting by Laurent, appeared to be identical with polio-encephalitis as seen this year. The virus of poliomyelitis was now the common cause of a meningo-encephalitis and of a benign type of lymphocytic meningitis.

## Correspondence

### Travel Abroad for Health

SIR,—The approach of winter brings to the fore the question of tuberculous patients in Switzerland. The need for the greatest economy in Swiss francs is obvious, but the means taken to serve this end are open to doubt. In order to obtain an allocation of Swiss currency for treatment purposes the patient has to present to his bank a certificate signed by two doctors stating that unless he goes to Switzerland "his life is endangered." As a result of this wording, advanced cases, which cannot be expected to benefit from any form of treatment anywhere, are easily accepted for treatment, and waste of Swiss francs is almost inevitable. With patients likely to benefit from Alpine treatment the position is more difficult. Some doctors presumably satisfy their consciences with the thought that there is danger to life in any case of tuberculosis not firmly arrested; others, in attempting a more literal interpretation of the regulation, regretfully refuse to give the necessary certificate, because they do not consider their patient's life immediately threatened.

I maintain that this state of affairs is highly unsatisfactory and that some means should be found to lay out our limited currency to better advantage. In general I do not think that the average patient recovers either more rapidly or more certainly in Switzerland than in Great Britain. I have seen no reason to alter this pre-war conclusion in spite of the more plentiful and varied food now obtainable in Swiss resorts. The crux of the problem is that sanatorium vacancies can be obtained much more quickly in Switzerland than in this country, and, so long as this is the case, who can say that a patient's life is not endangered by remaining untreated in this country, however early and slight his lesion may be? So long as our sanatorium waiting-lists are so unwieldy it is to be hoped that the authorities will be as lenient as they can be in granting permits for the utilization of the large reservoir of Swiss sanatorium beds immediately available; but, if the currency is not to be largely wasted, careful selection of patients is necessary.

No good can come from sending advanced cases with much reduced vital capacity; a winter in the Alps cannot be expected to close chronic cavities unsuitable for collapse therapy. Nervous, highly strung patients are liable to respond to altitude by insomnia and tachycardia and may have to be sent home. Chronic bronchitis in the young is usually benefited but in the elderly is more likely to be aggravated by the cold dry air of the Alps. The low barometric pressure is alleged to increase the tendency to haemoptysis, but my own observations do not confirm this belief. Altitude stimulates metabolism, and the patient must have sufficient reserve of energy to respond to the stimulus. Febrile, toxic patients and those of markedly asthenic build usually do better at low altitudes.

Numerous as these contraindications are there remain large numbers of patients, mostly of fairly robust physical and mental constitution, whose progress towards recovery can be expected to be at least as rapid in the Alps as in this country; but climate in itself rarely changes the outcome of the disease. One serious drawback to Alpine treatment is the practice of many Swiss physicians of so frightening British patients regarding the supposed danger of wintering in England that the rehabilitation of many of them as useful citizens has been seriously interfered with.

In present circumstances the best policy would appear to be to select, as far as possible, candidates for Alpine treatment from among those who have already had some months of institutional treatment in this country. Advanced or toxic cases and those likely to require major surgery could in this way be excluded. Each patient sent to Switzerland would free a bed for a more recent case on the waiting-list. Selection of cases on these lines has been practised by the Queen Alexandra Sanatorium Fund during the last two years and has been found considerably to reduce the wastage of money on unsuitable cases. If similar criteria were used on a national scale unfairness would be avoided and considerable waste of precious currency on unsuitable cases would be saved.—I am, etc.,

ANDREW MORLAND.  
London, W.1.

### The Extent of Neurosis

SIR,—This vital and important subject has elicited an interesting correspondence. I venture to say that it can be studied only in relation to fear, its nature, its distribution, and its source. Up to the close of the Victorian era life for the ordinary citizen was a matter of competition. The worker had to find a job and keep it, or face suffering for himself and his family (though not actual starvation). This fear was real and well-nigh universal, but the results of this kind of fear produced the finest kind of work in quality and quantity; and there was little neurosis.

There followed the Socialist outlook which has developed all through the present century. Fear—economic and social—has been gradually eliminated till it matters little to the worker whether he is in work or in benefit. Taking a superficial view this should reduce the extent of neurosis, but on the contrary it has increased enormously. In other words, the elimination of the fear motif has also eliminated the response of effort. Thus we get a situation in which individual effort becomes useless or even detrimental, and economic advancement depends upon an identification of the individual with the group. In other words, a higher standard of living is no longer achieved by an effortful reaction to economic fear and anxiety. Now it is to be obtained by identification with the herd and an attitude of passive solidarity with the group. In other words, the effect of economic stringency is to talk of strikes rather than to concentrate on effort. And no one can blame the individual worker for accepting the change, which has come so gradually and come from his political leaders.

But we are entitled to look ahead and to ask ourselves, "What will be the next phase?" For the sake of argument let us accept the Russian claim that in the U.S.S.R. there is no neurosis. That means that economic anxiety is geared to effort, and if rumour is to be believed it means that the worker gives of his best lest he should find himself in Siberia. Certainly any passive attitude to the group solidarity is not encouraged. There are many other aspects of this question which cannot be discussed within the limits of a letter, but the more we study it the more we are brought back to the essential relationship between fear and effort.—I am, etc.,

Harrow, Middlesex.

H. CRICHTON-MILLER.

SIR,—The provocative has its place among the artifices of discussion, but surely it loses its tang when it is employed too bluntly and without nuance. Dr. Arthur Dearlove (Oct. 11, p. 590), describing the inadequacy of the treatment which the neurotics he has referred to psychiatrists have received, declares: "The results are, roughly [sic]: cured, nil: improved, nil."

It is evidently not the intransigence of the neurotics of Dorset he is referring to, as he reflects upon the general impotence of psychiatrists later in his letter. Dr. Dearlove has no doubt acquainted himself with at least some of the numerous follow-up studies which have been published. Is it to be assumed that he meets them not merely with the "retort courtoise" but with the "lie circumstantial and the lie direct"?—I am, etc.,

London, W.1.

FREDERICK DILLON.

### The G.M.C. and Medical Education

SIR,—Mr. A. Wilfrid Adams's letter (Oct. 4, p. 545) was both useful and interesting, but it lands us in a quandary: a student while preparing for his licence to practise must first learn those things that he will want to know when he begins to learn how to conduct general practice; then and only then he has to begin to learn the art of practice. The suggestion of a year with a reputable general practitioner is accompanied by a liability to misuse or indifferent use. The old apprenticeship unfortunately began at the wrong end.

Would it not be more effective to attach a newly passed medico to a health centre, when available? Here he would have the advantage of taking an active part in the general medical practice of his seniors in all the varied services—early diagnosis, observation of conditions not yet labelled, practice in the consulting-room and in the patient's home; here observe the probabilities of treatment being successfully carried out, the need for proper sanitation or prevention; not only these sides of practice, but also work in the hospital to which the centre

is attached. In this way he would learn to associate his previous hospital experience with actual practice among patients under conditions new to him. Here, without prejudice, he could observe the results of treatment, immediate and remote.—I am, etc.,

Midford, nr. Bath.

CHAS. E. S. FLEMMING.

### Mercurial Diuretic

SIR,—I believe "neptal" (mercuric salicyl amino-acetate) is considered the safest and least toxic diuretic of the large group of mercurial diuretics, while it is simple in use since its efficacy does not depend on urinary pH. Since, unfortunately, it seems liable to cause prolonged aching pain, however well spread throughout skeletal tissues, probably many employ it—rightly or wrongly—by the intravenous route.

Dr. A. G. Oettlé (Oct. 4, p. 530) sounds a warning note in this connexion. His article interested me very much, since in 1945 I had an unpleasant experience with this drug, which was very probably an acute poisoning of the conducting tissue of the heart and was at all events a near-fatality. I was continuing a series of injections which a middle-aged cardio-renal female patient had received (2 ml. tri-weekly, bi-weekly, and finally weekly) from another practitioner and from which she had derived much benefit. Two injections were wholly uneventful: my third (her 28th or 29th) was almost disastrous, and would certainly have been so if I had not paused to fill the syringe by reflux after 1 ml. had very slowly entered the vein. She complained of such severe faintness and precordial constriction that I stopped the injection. The attack was much as Dr. Oettlé describes, dyspnoea and syncope being followed after a few minutes by an epileptiform convulsion.

I never doubted it was a Stokes-Adams phenomenon until long afterwards. I knew little of the history beyond that the patient was a cardiac case of long standing who had suffered in adolescence from several mild attacks of rheumatism. Two types of Stokes-Adams syndrome are described—a syncopal and an epileptiform. In this patient both appeared to develop successively. Following the attack a severe degree of heart block was sufficiently obvious from the extremely slow pulse with rapid jugular pulsation. An E.C.G. confirmed this and appeared to clinch the diagnosis of Stokes-Adams attack. I was fortunate in that symptomatic treatment carried out in this firm conviction at least did not prevent recovery, but on reflection I feel sure that it was I who accidentally "did the bundle in" and not a senior and most capable colleague who had treated the patient for some time in ignorance of a pre-existing heart block. Some Stokes-Adams attack—if it were such.

The most surprising feature of the case was the patient's bravery in submitting later to an apparently similar course of treatment, and one greatly favoured in France though not, I think, in England—i.e., intravenous injections of sterile "novocain" (procaine hydrochloride). The recommended dose of 10 ml. of 1% solution can be much exceeded with apparently complete safety, although large doses cause a transient complaint of paraesthesiae in fingers and other extremities. Very bold doses are given by some French physicians, who employ the drug as an antispasmodic agent in treating a diversity of spastic conditions, ranging from migraine through the asthmas and intestinal spasms to passing calculi (renal and biliary). As an antispasmodic agent I do not suppose novocain is ever likely to supplant atropine or pethidine but it has the merit of instantaneous action, and can be most useful alone or as an adjuvant. It is interesting to watch its action on the x-ray screen as regards intestinal spasms, and to employ it to diagnose—e.g., spasmodic dysmenorrhoea from other varieties (it does not, intravenously, appear to act, even briefly, as a general analgesic).

For nephrosis, procaine injections repeated at regular intervals are favoured by French physicians, it seems. The head of a hospital department demonstrated several cases for my benefit. Can anyone with experience of novocain confirm or refute the suggestion that it could replace mercurials? It can only be a palliative, but so are the latter; and, apart from this rare intravenous risk, are they not always dangerous to the old and frail, even intramuscularly? The patient is no doubt very often in a parlous condition before these powerful drugs are resorted to, but these drugs often seem to precipitate renal

failure, and, as the Greeks advised the making of a will before purgation with the hellebore, were it not well to advocate this procedure before diuresis with the mercuri?—I am, etc.,

PETER PARRY.

### Sympathetic Disorders in Poliomyelitis

SIR,—Following the annotation on "Sympathetic Disorders in Poliomyelitis" (Oct. 11, p. 579) might I make a few observations on muscle pain? It is a well-known fact that normal muscle, if exercised to excess, becomes painful and tender—presumably a defence mechanism to prevent a repetition of abuse before recovery has taken place. Everyone knows the "first game of the season" stiffness and tenderness, which may be excruciating and persist for several days. To turn to the abnormal: having slept beneath a ship's blower in the Tropics and awoken with a "stiff neck," one's conclusions are as follows. The reaction to the fall in temperature of the exposed part was that of local shivering or fibrillary twitchings of the muscles in question—in this case the trapezius and sternomastoid of the affected side—summing over a prolonged period to produce the same phenomena as of excessive general contraction—i.e., pain and tenderness.

From the electromyographic findings in poliomyelitis can one postulate an initial pathological stimulation from the diseased anterior horn cells invoking the protective mechanism described above?—I am, etc.,

Twickenham, Middlesex.

D. F. REES.

### BAL in the Treatment of Gold Dermatitis

SIR,—In view of the articles which appeared in the *Journal* of Oct. 4 concerning the therapeutic uses of British anti-lewisite, the following case report may be of interest.

#### CASE REPORT

The patient was a woman of 56 who for six months had complained of increasing pain in both wrists, hands, and fingers. A clinical diagnosis of early rheumatoid arthritis was made and intramuscular injections of "myocrisin" were commenced. The E.S.R. had not been done, but the urine had been carefully examined and was repeatedly checked.

A system of increasing dosage at weekly intervals was employed, and at the end of eight weeks a total of 0.4 g. had been given. The day following the last injection an irritating erythema appeared, which quickly changed to a macular rash, and after a week the typical appearances of an exfoliative dermatitis due to gold were evident. The condition was severe and resisted every method of treatment.

After eight weeks of trial and error injections of BAL were commenced. The preparation used was a 5% solution in 10% benzyl benzoate in peanut oil. Daily injections of 2 ml. were given for five days, with immediate amelioration of the symptoms. The dermatitis, however, did not completely disappear, and after a period of six weeks of comparative comfort for the patient the condition worsened. Further daily injections of BAL 2 ml. were given for seven days, and the dermatitis once more subsided, the improvement this time being maintained. The injections produced two large abscesses in the buttocks which had to be drained. The arthritis, which responded well to the gold therapy, has so far showed no signs of recurrence.

### The Weil-Felix-Wilson Reaction

SIR,—What is commonly called the Felix-Weil reaction is in reality the Felix-Weil modification (or variation) of the Wilson typhus reaction, for Wilson's (now Prof. W. James Wilson, of the Queen's University, Belfast) discovery of the agglutination of organisms of the *B. coli* and *Proteus* type was made in 1908 and 1909, whereas it was not until the first world war that Felix and Weil carried out their work, publication regarding which was made in 1916. Personally I have every reason to remember the discovery, as I was the first human being on whom it was tried for diagnostic purposes—in March, 1908.

The following is a brief outline of the genesis: From the end of December, 1906, for several years Belfast was visited by a very severe epidemic of cerebrospinal fever, and a considerable amount of work was carried out at Queen's College (now University) on the bacteriology of the meningococcus. While this epidemic was in progress I happened to be R.M.O. in the City Isolation Hospital at Purdysburn, where in my time (about

one year eight months) about 360 cases of the disease were treated (a paper by me describing the outbreak was published in the *Practitioner*, 1915, 94, 831).

Wilson during this period had been making investigations at Queen's regarding the bacteriology of cerebrospinal fever and had been struck by the heterologous agglutination effect of the blood serum of patients suffering from the disease (see *Journal of Hygiene*, 1909, 9, 316). While the epidemic was in progress an outbreak of typhus fever occurred in the city, and almost forty of the cases were admitted to Purdysburn during my residence there, and I suggested to Wilson that if he would care to make investigations about the disease I would try and get him as much material as possible. Wilson then started his investigation, and samples of blood, faeces, urine, etc., were taken by us from patients who, we considered, were suffering from undoubted typhus. Wilson found before long, as in cerebrospinal fever, that there were heterologous agglutinations in this disease also. He found that the serum of typhus agglutinated *B. typhosus* and also bacilli obtained from the faeces and urine of typhus patients. Wilson's first publication on this matter appeared in the *Transactions of the Ulster Medical Society*, session 1908-9, in a joint paper by Wilson and myself (but I must state here clearly that it was Wilson who was entirely responsible for the discovery of the agglutination effect).

Near the end of my residence time in the hospital I developed an acute febrile condition which resembled typhus. There was doubt at first, and my serum was tested. An agglutination reaction was found. This condition began very suddenly, without preliminary catarrhal symptoms, and was accompanied by a rash that was a cross between that of measles and typhus. It ended with a sudden drop of temperature on the twelfth day. Wilson's next paper was published in the *Journal of Hygiene*, 1909, 9, 316. In the *Journal of Hygiene*, 1910, 10, 155, a further paper entitled "The Etiology of Typhus Fever" was published by him. Among his conclusions are the following:

"(4) From the faeces of one case a variant form of *B. coli* *communis* was cultivated on which the blood serum of 17 typhus fever cases was found to have three to ten times the agglutinative effect of normal serum.

"(5) From the urine of two cases a bacillus resembling *B. coli* *communis* but having no action on lactose was cultivated. This bacillus was agglutinated in dilutions of 1:50 and 1:100 by the serum of the cases but not by normal serum."

This bacillus from the urine Wilson regarded later as a urinary variety of *B. proteus* ("The Wilson-Weil-Felix Reaction in Typhus Fever," *Journal of Hygiene*, 1920, 19, 115), and pointed out that it is probably similar to the X2 strain of *B. proteus* first used by Weil and Felix. Weil and Felix in "X19" obtained a more sensitive organism for the typhus reaction than X2; Wilson also, in U2, a bacillus of the colon-paratyphoid group, obtained an organism not only more sensitive than his original one but as sensitive as X19 of Weil and Felix in certain cases of typhus fever. Comparisons are given regarding this in Wilson's paper "A Further Contribution to the Serology of Typhus Fever" (*Journal of Hygiene*, 1927, 26, 213). This bacillus U2 is named so on account of its similarity to the original U discovered by Wilson in 1908, which was found to be agglutinated by the serum of typhus fever patients with three to ten times the effect of normal serum ("Bacteriological and Cytological Investigations of the Blood in Typhus Fever Cases," by W. J. Wilson and E. H. M. Milligan, *Transactions of the Ulster Medical Society*, Session 1908-9).

It should be remembered that in addition to the Felix-Weil modification of Wilson's typhus reaction there are other modifications such as those using *B. pyocyaneus* (Kreuschen, 1918; Neukarsch and Kreuschen, 1919; Sampietro, 1920; Wilson 1922), and the *Coccobacillus byzantinus* (Beguét, 1921).

In view of the above observations I think it will be admitted that it is reasonable and right to suggest that in future the Felix-Weil reaction should be called the Felix-Weil modification of the Wilson typhus reaction, or, more shortly, the Weil-Felix-Wilson reaction (W.-F.-W. reaction). Wilson was undoubtedly its discoverer; Felix and Weil have the credit of developing it, expanding it, and getting it more widely used during the first world war.—I am, etc.,

Glossop, Derbyshire.

75, New Cavendish St., London, W.1

*A Delicious Concentrated*  
**VITAMIN FOOD**

'VIMALTOL' presents special advantages to the physician requiring a product which incorporates important vitamins in a form entirely pleasant and acceptable to every patient.

'Vimaltol' is made from specially prepared malt extract of high protein content, yeast—one of the richest sources of vitamin B<sub>1</sub>—and Halfbut Liver Oil, an important source of vitamins A and D. It is also fortified with additional vitamins and mineral salts, and is deliciously flavoured with orange juice.

'Vimaltol' is standardized to contain in each fluid ounce: 648 international units of vitamin A and 1350 of vitamin D; also 0.3 milligrammes of vitamin B<sub>1</sub>, 4 of Nicotin (P.P. vitamin), and 48 of Iron, in a readily assimilated form.

'Vimaltol' is thus an important aid in the treatment of the many abnormal conditions resulting from the deficiency of one or more of the essential vitamins in the average everyday dietary.

The routine use of 'Vimaltol' helps normal development of the growing organism and the maintenance of correct metabolism, while raising the general resistance against infection.

**VIMALTOL**

Scottish Depot: 665, Gt. Western Road, Glasgow, W.2.

## A MEDICAL COMMONWEALTH

Kapilin is as familiar to the obstetrician in India as Kapilin is to his counterpart in Britain: both names represent the same Glaxo vitamin K analogue preparations. Such vowel changes are sometimes necessary in some countries . . . in Havana, for example, Fersolin names the efficient iron treatment that London knows as Fersolate.

Discuss vitamin D injections for allergic disorders with medical men in Egypt or Australia and you will hear of Calci-Ostelin. Discuss chilblain treatments with British practitioners and someone is sure to mention Colloidal Calcium with Ostelin. Both are one and the same preparation by merely a different name.

Not all the names of Glaxo products change on leaving England. Prepalin is still Prepalin in Prague; amethocaine hydrochloride is Anethaine as much in Colombo as in Capetown; Mersagel is known wherever dhotie itch is prevalent, whether in Syria, Singapore or the Sudan; and Penicillin Glaxo is demanded as such the world over.

Almost every product of Glaxo is available almost everywhere . . . reflecting an export-mindedness that dates back to the beginnings of the Company, and forward to the re-establishment of Britain's leadership in every corner of the world.

### Auricular Inflammation

SIR,—I had opportunity to notice during ten years of service in China four cases of a peculiar otochondritis in the cartilage of the external ear, with the signs of acute inflammation, redness, swelling, and localized pain. In such a case the auricula is tender and sometimes shows an oedematous swelling, which subsides on pressure, causing considerable pain. This otochondritis disappears after a few weeks, leaving the auricula enlarged and the cartilage thickened. After some time—weeks or months—the next attack would set in with a very similar course, possibly a bit of fever, and clear up again. After years, as I have seen in one case—a middle-aged woman of Chinese race—the auricula becomes hard as a board, inflexible, and stands at a right angle to the sagittal plane of the body. The skin is dark brown, hyperpigmented, and the patient complained of being unable to lie on the diseased side.

I could not find any cause for this disease. One patient had a positive Kahn test, and antisyphilitic treatment had no influence on the course of the disease. I tried local application of tincture of iodine, cold and hot fomentations, and sulphonamides by mouth, all *sine effectu*. Could somebody enlighten me on this subject or relate similar experiences, especially in tropical countries?—I am, etc.,

London, W.1.

W. WINTERSTEIN.

### Treatment of Varicose Veins

SIR,—The article on the treatment of varicose veins by Prof. A. M. Boyd and Mr. D. J. Robertson (Sept. 20, p. 452) contains points of much practical interest, some of which call for further discussion. The 12 cases of deep thrombosis seen in a space of five months must surprise most of your readers. Many years ago I had one such case in a man of 70 to whom I had given some injections of, I think, quinine below the knee. The following week he reported with his whole saphena vein thrombosed to the groin. He did not turn up again for a few months and then said that in the meantime he had had pneumonia, but my inquiry to his doctor as to whether he thought the "pneumonia" was an embolic condition or whether it was a primary condition which might have caused the deep thrombosis failed to elicit a reply. I have never seen deep thrombosis following groin ligation plus injection. I wish the authors had said more about the technique used in the 12 cases and the amount and nature of solution employed.

The authors repeat the usual statement that it is important to ligate the saphena tributaries in the groin to prevent recurrence and show a photograph to illustrate a recurrence where this has not been done. As it is virtually impossible to get a clear view of the sapheno-femoral junction without dividing these tributaries it is safe to assume in such cases of recurrence that effective ligation has not been done, but the point is academic. The writers refer to temporary oedema of the ankle and lower part of the leg which may follow injections alone. I have had this annoying complication from time to time, but, owing to its transient nature, have wondered whether it might be caused by unduly prolonged reflex spasm spreading to some of the sub-fascial veins. I do not dispute their explanation, however, that it may be due, in part at least, to some degree of thrombosis in the deeper veins.

The authors do not refer to sclerosing agents, but the choice of these is of some importance. Thirteen years ago I started experimenting with carbolic-glycerin mixtures of various strengths, and for the last eight years have used a solution of 2% liquid phenol in 30% glycerin measured by volume. This solution is an adequate sclerosing agent, seldom causes undue reactions, is relatively harmless to the subcutaneous tissues, possibly due to the hygroscopic qualities of the glycerin leading to its dilution with tissue fluids, and is cheap and antiseptic, and can be stored in bulk. Haemoglobinuria has not been reported from its use, though it occurred at times with higher strengths. 15 ml. is the standard amount given at any one sitting, though 20 or 25 ml. has frequently been injected in divided doses. The only disadvantage to report is that vertigo sometimes occurs after injecting 5 ml. at one point, but this passes off in a minute or so, and further injections do not cause a return of the giddiness. A modification of this solution has been reported on by Dodd in this *Journal* (March 15, p. 366).

Another point in treatment I may be allowed to mention here is that the saphena vein may be thrombosed by mechanical damage

to the intima. For this purpose a "scraper" is used. This instrument consists of a metal tube (25 in. (63 cm.) is a convenient length) with a screw joint in the middle for ease of portability; and at the end is fixed a metal cylinder with a rounded end and roughened surface, which is passed down the saphena trunk after its division in the groin. The instrument will not pass a marked tortuosity in the vein, but obstructing valve cusps can be broken down safely with a few judicious jabs, and in most cases the roughened cylinder will reach at least as far as the knee, and in large veins can often be pushed its full length to the middle third of the leg. During this proceeding escape of blood is prevented from the upper end of the vein by a piece of catgut passed twice round the vein, the ends being held by an assistant. In the case of the left leg, when the scraper has been passed to its limit with the right hand, the fingers of the left hand are pressed against the vein, with the little finger opposite its lower end, and the scraper is moved up and down a few times and rotated if desired. This procedure is repeated a hand's breadth at a time in an upward direction till the whole length of vein is dealt with. If it is desired to inject the vein at operation, the tube of the instrument is filled with solution to displace air before it is passed, and when it has been pushed down to its limit 10 ml. of the solution mentioned above is injected and the "scrapping" then proceeded with.

Boyd and Robertson give evidence to suggest that injection below the knee is unlikely to be harmful, and, as mechanical thrombosis of the trunk above the knee cannot affect the intima of the deeper veins, the technique described appears to meet their criteria of safety in treatment. This may account for the lack of anxiety I have had with the method during the past four to five years.

The instrument is made by Messrs. Phillip Harris and Co., 44, Edmund Street, Birmingham, 3.—I am, etc.,

Birmingham.

J. W. RIDDOCH.

### Homosexuals in Prison

SIR,—All workers in this field welcome Dr. F. H. Taylor's article (Oct. 4, p. 525), which puts forward the evidence of facts to take the place of speculation and theory. As he rightly says, it is the true invert whose case is of most interest, and several matters arise from his report of the 13 prisoners of this type who came under his care.

First, the facts refute a popular misconception that the natural homosexual is attracted to small boys, as among 13 true inverts only one was interested in boys. An invert turns towards adults of his own sex as naturally as a normal man is sexually attracted by a woman as a potential mate rather than by a child.<sup>1</sup> Homosexual offences against children are almost exclusively the prerogative of the pseudo-homosexual group, wherein over 50% exhibit mental subnormality, many of them being of the same mental age as the children they seek to seduce.

Secondly, the evidence from the series of true inverts might be used to give support to the theory that seduction in early youth or childhood is a dominant factor in the production of homosexuality, which is the view taken by Sir Norwood East and W. H. Hubert<sup>2</sup> and opposed by E. A. Bennet and others.<sup>3</sup> This point of course is supremely important in connexion with the social as well as the clinical aspects of homosexuality. But the support given by this investigation is considerably weakened by a closer examination of the evidence which Dr. Taylor quite impartially puts forward. Among these 13 men androgynous physique was present in six cases: obviously the physique could not have been caused by the seduction, though the reverse might well have been true. The fallacy of *post hoc ergo propter hoc* can be excluded only by comparable statistics from a control series of non-homosexual prisoners. Some form of homosexual activity which can only be described as seduction is the experience of large numbers of public-school boys during their early teens, the incidence varying widely from school to school, but in some places it is certainly of the order of 50%: a similar figure is probable in other social strata, and it may well be even higher among the sub-intellectual group that contributes so largely to the prison population. The postulated connexion between seduction and later homosexuality can therefore be established only if a similar investigation among a control series of prisoners reveals a difference that is statistically significant. It is to be hoped that this evidence will be forthcoming, for without a knowledge of the facts further discussion is useless.

Thirdly, the evidence from Brixton prison appears to support the alleged connexion between natural homosexuality and sexual perversion, which is the view put forward by Sir Norwood East and W. H. Hubert<sup>2</sup> and Clifford Allen,<sup>3</sup> and opposed by Havelock Ellis and others. J. A. Symonds (in an unpublished essay) admits that, although "a far larger proportion of mental disturbance and nervous hypersensitivity can be proved in Urnings than in normal men; in a vast majority of cases the Urning owing to present laws and social prejudices cannot, like other men, obtain a simple and easy satisfaction of his inborn sexual desires, which for him are as natural as swimming to a fish. It is this forcible suppression of an instinct so deeply rooted in his nature which originates the morbid symptoms that may often be observed in the Urning." The same author attributes to homosexual fears and guilt "at least half of the suicides of young men." Bernard Shaw has stated categorically that "homosexuality implies no general depravity whatever." The validity of evidence to the contrary which might be drawn from the present series of cases is dependent entirely upon the support of a series of controls. An examination of the 198 prisoners (presumably males) charged with heterosexual offences during the same period would probably yield a percentage of degeneracy comparable with that found in the homosexual group, and this again is valuable evidence that should be available before discussion can proceed with profit. But in any case it would be as unreasonable to draw conclusions about clinical and social (as distinct from anti-social) homosexuality from a series of homosexual prisoners as to base arguments concerning normal heterosexuality on the findings in a similar group of heterosexual offenders.

General deductions as to treatment would be open to the same error. It would be as unlikely that patients from this series of cases could respond to psychotherapy by making a good social adaptation (even if their homosexuality were left untouched) as that their heterosexual fellow prisoners could be educated to become happy fathers and husbands. Only the dregs of both classes find their way into the prisons, and unfortunately it is only from this group that statistical evidence about homosexuality can be collected. This evidence is not applicable to the socially adapted natural invert.

Lastly, may the opportunity be taken to correct an error that appeared in the *B.M.J.* last year, and which still stands unchallenged, namely—that "buggery" is a scriptural term? The appellation of *bougre* (Fr: Bulgarian) was given to the ultra-puritanical sect of the Albigenses in the South of France during the eleventh century A.D. on account of their association with the Bogomils, or Bulgarian heretics—heretics only by reason of their steadfast and unyielding opposition to Catholic orthodoxy, for which the sect was exterminated in the Albigensian "Crusade" of 1209.<sup>4</sup> The imputation of unnatural vice (which has been entirely discredited) was the invention of the fertile mind of Pope Innocent III, who was himself a repressed homosexual and a fanatical persecutor of all forms of sexual heterodoxy real or imagined.

Cornwall.

## Another Foetus Cries

SIR.—Interest and speculation have been aroused by reading Dr. E. Curphey's letter (Sept. 27, p. 508). During induction of labour on Oct. 8 in a para-2 woman at the 39th week of pregnancy by means of a Drew-Smythe catheter I was astonished to observe the same phenomenon. The head was in the brim of the pelvis. While manipulating the catheter I followed my usual custom of engaging the patient in conversation. On this occasion I was asking her whether she had read in the papers of the baby who cried before being born.

After withdrawing 24 oz. (680 ml.) of liquor I left the catheter *in situ* for another minute in order to remove any further liquor

that could be expressed from the uterus. The baby was particularly active and moved the catheter several times. Immediately after withdrawing the catheter the mother said to me, "My baby is crying too." Needless to say I did not believe her and suggested that I had put the idea into her head. Half a minute later I asked the midwife in attendance to listen to the foetal heart. On placing the foetal stethoscope rather near the foetal head than usual, she replied excitedly, "The baby crying." At this stage, from my position at the foot of the patient, who was still in the lithotomy position, I heard a sound resembling a smothered gurgle. I then used the foetal stethoscope and without a doubt heard the baby cry.

The baby was subsequently extracted with forceps, alive and well, 15 hours later. I too was unfortunate in not getting further medical confirmation in order to convince my sceptical colleagues, and the baby could not be induced to repeat the performance.

George H. Ryder, however, has reviewed<sup>1</sup> some of the 12 authentic cases of vagitus uterinus reported in the literature between the years 1800 and 1941. He found that there was foetal mortality of nearly 1 in 5, and in 85% of cases operative interference was required. One cannot, of course, infer that the mortality or the interference was directly related to impending asphyxia of the foetus. Munro Kerr in his textbook<sup>2</sup> has reported that on two occasions he heard the foetus cry *in utero*, while an internal version was being performed. It is obvious that the introduction of air into the uterus is necessary before the foetus can cry, and possibly somatic stimulation from the introduced instrument or hand also helps to overcome the inhibition of respiratory movement which Barcroft has found to exist during the latter period of foetal life. In this particular case both conditions seem to have been present.—I am, etc.,

Oxford.

## Vaginal Temperature

SIR.—The case reported by Dr. John Hankinson (Oct. 11 p. 574) of a woman having passed a clinical thermometer into the bladder while endeavouring to take her vaginal temperature should serve to emphasize the undesirability of this extraordinary procedure. That the recording of basal temperature is of great value in the study of cases of infertility will be acknowledged by most of those who have had experience of them and have taken pains to see that their patients record them properly; that the determination of the "safe period" by means of basal temperatures can be a satisfactory contraceptive technique might also be allowed, though doubts might validly be expressed concerning this; but that patients should be subjected to the inconvenience and, to judge from Dr. Hankinson's report, the potential dangers of inserting clinical thermometers into their vaginae in order to estimate their basal temperatures seems utterly ludicrous.

Is the temperature of the vaginal cavity supposed to carry some especially recondite significance from the standpoint of conception, its failure, or its prevention? Or is the placing of a clinical thermometer beneath the tongue, followed by closure of the lips, too simple a procedure sufficiently to impress the patient that the temperature record so obtained is of value? If anyone who has been advising his patients to take their vaginal temperatures does not realize that oral temperatures taken in the same way will yield just as much information, then the best advice that can be given is that he should try the latter technique and see for himself. And the same can be said for rectal temperatures, the taking of which is scarcely less inconvenient or distasteful to the patient than is that of vaginal temperatures.

That the situation as it appears to exist is almost comic can be judged from the suggestion of Dr. Hankinson that a specially designed thermometer should be employed for taking vaginal temperatures, which calls to mind the true instance of a woman, instructed to take her vaginal temperatures, apologizing for not having done so because none of the chemists' shops she had tried had stocked a vaginal thermometer.—I am, etc.,

London, N.W.6.

G. I. M. SWYER.

## POINTS FROM LETTERS

## Pure Anti-E Agglutinin in the Serum of an Rh-negative Woman

Dr. R. H. MALONE (Sheffield) writes: In continuation of my letter . . . (Sept. 13, p. 433), Dr. Mourant has informed me that Mrs. C.'s serum has been re-examined and found quite definitely to contain incomplete anti-D in addition to anti-E. The baby's genotype was R,r (cDE/cde).

## Mind and Matter

Dr. ALEXANDER LEITCH (Westbury-on-Trym, Bristol) writes: Having read with interest Dr. E. R. Banner's speculations on the mind-body relationship (Sept. 13, p. 433), I feel that, while Dr. Banner develops his theory quite logically, the superstructure is based on such a remotely conceivable possibility (or premise)—i.e., "it is not wholly inconceivable that every physical unit (say, every electron and proton) is the body of a very simple mind." It might, in fact, almost be regarded as a *reductio ad absurdum* of the superior theory of Adolf Meyer of "psychobiological integration," which, put very briefly, postulates that, from the simplest beginnings of organic life without any neural structures, through organisms of increasing complexity, first differentiated into oval and caudal parts, on to organisms with rudimentary brains, and so on to man himself with his unique (in the animal world) cerebral development, there appeared at some point in the evolutionary chain a form of consciousness; and as the complexity of the neural structures grew so the attributes of mind increased, so as to adapt and integrate more perfectly the organism with its environment. This process culminates in man, with his uniquely developed cerebral structures on the one hand and his intellectual capacity on the other.

## Sacro-iliac Strain

Dr. C. J. PENNY (Winchester) writes: The provision of belts for patients suffering from sacro-iliac strain is a matter of some difficulty in these days. This condition occurs not infrequently during pregnancy, and recently a patient of mine who was proceeding to India shortly came to me for treatment. There was no time to get an appropriate belt, and it occurred to me that a sheet-rubber bandage might give the necessary support. I accordingly applied such a bandage over the underclothing and was pleased to find that the patient's symptoms were completely relieved. Since then I have used the same apparatus in other cases of pregnancy and the patients have found them to be comfortable, easy to apply, and to give them the support necessary to relieve their symptoms. . . .

## Manic States in the Far East

Dr. H. HARRIS (Lingfield, Surrey) writes: Dr. R. F. Tredgold in his interesting paper on "Manic States in the Far East" (Oct. 4, p. 522) concludes that they may be due to "the sudden release of tension and the consequent change in the tempo of work." It might be of interest and value to analyse statistically the relative incidence of manic reactions in the general community after V J day.

## Polionmyelitis

Dr. R. A. Russell Taylor (Wakefield) writes: On June 1, 1947, Pinderfields Emergency Hospital, with the approval of the Ministry of Health, opened a special department here for the treatment of the after-effects of infantile paralysis. It may be of interest to the medical profession to know that we have to-day admitted for treatment our one-hundredth case. Our youngest case is that of a child of one week old, and we have a patient who is five months' pregnant, also suffering from this condition. . . .

## Convalescent Homes

Dr. BARBARA J. HICK (Broadstairs, Kent) writes: I am very glad to read in the annotation (Oct. 11, p. 580) that the Institute of Almoners has undertaken a survey of convalescent homes. After 15 years in practice among both sexes in various parts of the country my impression is that many patients are glad to get back to their own homes and have a rest. I particularly remember a man with valvular disease of the heart who had been given up by another doctor only a few months before. He was the type of case who should have been taught the value of relaxation with a view to a future of curtailed activity, but he returned tired out owing to the amount he had had to do at the convalescent home. Most places have an iniquitous rule that patients are not allowed in their bedrooms between 8 a.m. and 8 p.m. Some allow a rest in the afternoon if ordered by the patient's own doctor, but surely all patients should be able to go and lie down at any time when they feel the need for rest and quiet. About two years before the war I went round a home newly opened for women. There were only two settees in the whole place and they both looked extremely uncomfortable. . . . There is (literally) a crying need for homes for mothers and babies. A few were started in the years between the wars, but the supply is most inadequate.

## Obituary

## MACGILLIVRAY OF MACGILLIVRAY, M.D., LL.D.

MacGillivray of MacGillivray, twenty-eighth chief of the clan of MacGillivray, died at his home at Crail, Fifeshire, on Oct. 15 at the age of 82. He was for forty-five years surgeon to the Dundee Eye Institution and a former reader in ophthalmology at St. Andrew's University.

Angus MacGillivray was educated at Fordyce Academy and Aberdeen University, where he was an honours graduate in medicine and Struthers' gold medallist in anatomy. After studying at the Birmingham Eye Hospital and later in London, he was appointed assistant ophthalmic surgeon in Aberdeen. He went to Dundee in 1889 and was the first ophthalmic specialist in practice there. He gave many years of devoted service to Dundee Eye Institution, and after his forty-five years as senior surgeon he was appointed honorary consulting surgeon and director of the Institution. He also founded the department of ophthalmology at Dundee Infirmary and was surgeon there for over thirty years before becoming honorary consultant ophthalmic surgeon in 1925. It was not until 1935 that he retired from the post of reader of ophthalmology at the University of St. Andrew, and in 1937 he received the honorary degree of LL.D. He acted as eye specialist to the education authorities of Dundee, Angus, and Fife, and during the 1914-18 war he was consulting ophthalmic surgeon for the Dundee area. Later he became registrar of Dundee Military Hospital, was promoted major, and received the Territorial Decoration. About 1939 he gave up many of his activities and went to reside at Crail.

A keen Celtic student and archaeologist, he was Chief of the Dundee Highland Society in 1912, and was the author of *Our Gaelic Proverbs: A Mirror of the Past*, and also *The Highland Dress*. He published in 1916 a book on the bacteriology and clinical study of the eye and contributed a number of papers to the medical press. He was secretary of the Section of Ophthalmology at the Annual Meeting of the B.M.A. in 1898 and vice-president at the 1902 meeting. He was also president of the Dundee branch in 1924-5. From 1926 to 1939 he was county controller and county director of the Dundee branch of the British Red Cross Society, and he was a Commander of the Grand Priory in the British Realm of the Order of St. John of Jerusalem. He was at other times president of the Forfarshire Medical Association and of the Caledonian Medical Society.

He was twice married, and is survived by Mrs. MacGillivray and two sons, Angus Robertson, the heir, who was born in 1892, and Dr. Allister M. MacGillivray, ophthalmic surgeon in Dundee.

ALEXANDER THOMAS CAMERON, professor of biochemistry in Manitoba University since the close of the 1914-18 war, died in the Winnipeg General Hospital on Sept. 25 after a long illness. He was born in London and was educated at Edinburgh University, where he received his M.A., B.Sc., and D.Sc. He was also awarded the 1851 Exhibition Science Research scholarship while studying at University College under Sir William Ramsay. Later he worked at the Polytechnic Institute, Karlsruhe, Germany. In 1909 he settled in Winnipeg, being appointed lecturer in physiology and biochemistry under the late Prof. Swale Vincent. During the war he served overseas for four years with the R.A.M.C. On his return to Canada in 1919 he became professor of biochemistry and was soon recognized as one of the foremost authorities in that subject. In 1928 he wrote his *Textbook of Biochemistry*; in 1930, in collaboration with Dr. Frank D. White, *Practical Biochemistry*; in 1933, with Dr. C. R. Gilmour, *The Biochemistry of Medicine*; and in the same year *Recent Advances in Endocrinology*, which latter work has gone through six editions. His time was not entirely spent in teaching and writing. He did much research work in marine biology and became chairman of the Fisheries Board of Canada. For his services in this connexion he was recently honoured by the award of the C.M.G. He was an active member of the Scientific Club of Winnipeg; a fellow of the Royal Society of Canada, of the Royal Institute of Chemistry, Great Britain, of the Chemical Institute of Canada; and he was also a member of the Senate of the University of Manitoba. He is survived by his widow, a son and daughter, and one brother living in Montreal.—R.M.

Dr. LEE CHOO NEO, of Singapore, died on Sept. 7. Dr. Lee Choo Neo was for many years honorary treasurer of the Malaya Branch of the B.M.A., and vacated that post less than a year ago to take a vacation in Australia. She was responsible for the preservation of the local B.M.A. records during the war period, and the Association owes her a debt of gratitude. Dr. Lee, it is understood, had only recently returned from Australia to resume her private practice. She was the wife of Mr. Teo Koon Lim, and they had one son and two daughters.

Dr. THOMAS HENRY HARKER, who had been associated with Southport Infirmary for many years, died there on Oct. 4 at the age of 68. A native of Hampshire, Dr. Harker was a student of St. Bartholomew's Hospital. He qualified in 1903, graduated M.B. in the same year, and proceeded M.D. in 1905. Dr. Harker was at one time house-physician at the Brompton Hospital and resident surgical officer to the Children's Hospital, Birmingham, and to the Women's Hospital at Brighton. He served in the R.A.M.C. with the rank of captain in the 1914-18 war. He had settled in Southport in 1912, and he was appointed honorary assistant physician to the Infirmary there in 1920, honorary physician eleven years later, and consultant physician in 1938. He was also consulting physician to the Southport Convalescent Hospital. Not long ago Dr. Harker was appointed a member of the Liverpool Regional Hospitals Board, and he had been for many years a member, and formerly president, of the Southport Medical Society. He was chairman of the Southport Division of the B.M.A. in 1934-5. His chief hobby was gardening, and he was particularly expert in the cultivation of dahlias. At all times, however, his chief interest was in the Southport General Infirmary. He had been chairman of the board of management since 1940, and he attended a board meeting there as recently as Sept. 27. He leaves a widow, a son, and two daughters.

Mr. R. R. M. Porter writes: The sudden death of Dr. T. H. Harker so soon after his retirement from practice came as a shock to his many friends in Southport, and particularly to his colleagues on the staff of the Southport Infirmary. Harker was one of those rather rare members of the profession who combine high professional skill and sound clinical judgment with exceptional administrative ability. He was never obtrusive, but when he spoke on a subject he had considered it from every angle and had every relevant fact available, and his views were always sound, never partisan. He will be greatly missed by his colleagues. His whole life was devoted to his work, and his conduct was an example of the highest professional ethics, of calm competence, and of perfect courtesy at all times.

Dr. JOHN GOFF, who died in London recently, graduated at Glasgow in 1882, and proceeded M.D. two years later after studying in Berlin, Vienna, and Paris. He was house-physician at the Western Infirmary, house-surgeon to the Dispensary Skin Diseases, Glasgow, and later assistant master of the Londa Hospital, Dublin.

J. D. S. writes: The late John Goff was a remarkable man in many ways. My own intimate personal friendship with him began in 1924, when he was in general practice in Windlesham, Surrey, and lasted until he died. He was the very best type of practitioner, and was much loved by his patients, rich and poor. His life was devoted to his work, which was marked by great sympathy and much understanding. He was in the truest sense a good man, and will long be remembered by his patients and his friends. He was one of the oldest members of the British Medical Association, and was a regular attendant at both local and headquarters meetings. He had interests in golf and racing. A yearly visit to St. Andrew's was a regular habit, and he was rarely absent from an Ascot meeting. Up to last year he was walking five or six miles a day, and enthusiastically carried on his beloved church activities. His life was full and satisfying, and he had no regrets.

Dr. HUGH NASH BRADBROOKE died suddenly at his home in Horsham on Oct. 5 at the age of 47. He was educated at the Grammar School, Bletchley, and at Queen's College, Oxford, where he gained first-class honours in natural science. At the London Hospital he won the Anderson Prize in clinical medicine and the Letheby Prize in chemical pathology. He took the B.M., B.Ch. in 1925, the M.R.C.P. in 1927, and proceeded D.M. in 1934, taking the D.P.M. four years later. After holding a series of resident appointments at the London Hospital he went into practice at Abingdon, remaining there for eleven years. He took a keen interest in the affairs of the town, and served as a justice of the peace. He also played an active part in the work of the British Medical Association, and was a

representative at the annual meetings on four occasions. He was appointed assistant medical officer to the Oxford City and County Hospital at Littlemore, and clinical assistant to the department for nervous disorders at the Radcliffe Infirmary in 1938. The following year he went to Cliftonville. In 1940 he moved to Horsham, where he was in practice for two years. In 1942 he joined the R.A.F. as a specialist in neuropsychiatry, being invalided out in 1944. Since leaving the R.A.F. he had been honorary psychiatrist at the Prince of Wales General Hospital at Tottenham, neuropsychiatric specialist at the Ministry of Pensions, and clinical assistant in the department of psychiatric medicine at the Middlesex Hospital. Dr. Bradbrooke was keenly interested in aviation. As a pilot in the R.F.C. he saw service in France and Russia. Later he continued to keep up his interest in flying as a member of a gliding club, doing a considerable amount of experimental work himself. During the early part of the recent war he did invaluable work as the first commandant of the Horsham Air Training Corps. He was particularly successful in managing to inspire the greatest keenness and enthusiasm among the boys he trained. For the past two years he had suffered from increasing ill-health, and only those who knew him well could appreciate and admire the effort he made to carry on. He was loyal, sincere, and a very pleasant colleague. He will be greatly missed by all who had the privilege of knowing him. He leaves a widow and three children.—G. S. M.

## Medico-Legal

### DUODENAL ULCER AS AN INJURY

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The original Workmen's Compensation Act, introduced at the beginning of the century, provided compensation for workmen who suffered injury by accident. The courts have always taken the view that the workman ought to benefit by these Acts whenever a beneficial interpretation is possible, and quite early in their history the House of Lords decided that anthrax could be an injury by accident.<sup>1</sup> Since then many diseases have ranked as injury by accident, including a number which are not caused by infection, such as heat-stroke and Raynaud's disease. The courts have tended to reject need for proof of the occurrence of the mishap at any particular time, and to agree that an injury by accident may be caused by a continuous and cumulative process. The door to the admission of disease as an injury at work is opened still wider in the police pension cases, in which the concept of accident does not enter, as the applicant is only obliged to prove injury suffered in the execution of his duty.

In the latest of these<sup>2</sup> a Huddersfield officer, who had always showed exceptional devotion to duty, had for some months before the outbreak of the war been exposed to very long hours of duty and exceptional worry, with the result that he had irregular hours for meals and rest and eventually developed a duodenal ulcer; after unsuccessful medical treatment he had a partial gastrectomy. He applied for a special pension under the Police Pensions Act, 1921, on the ground that his state of health was brought about by his police service. The police authority regretfully decided that they had no legal power to grant him a pension, but the recorder allowed his appeal. The question came before the High Court, which confirmed the award. By an earlier decision of the same court, noted in these columns,<sup>3</sup> a constable was awarded a pension on showing that he had contracted tuberculosis attributable to his service.<sup>4</sup>

They considered that they ought to follow that decision, and that it applied to the present case. The fact that duodenal ulcer is not due to an infection they did not consider to be relevant. If, Lord Goddard said, the condition from which the man suffers is directly and causally connected with his service as a police officer, then he has received an injury in the execution of his duty. Whether if the case had been brought under the Workmen's Compensation Acts the ulcer would have been regarded as an injury by accident is a different question.

# 'CETAVLON'

brand

## CETYLTRIMETHYLAMMONIUM BROMIDE

'Cetavlon' is a synthetic cationic detergent consisting essentially of cetyltrimethylammonium bromide, a voluminous white powder, readily soluble in water. The solution has a low surface tension and exhibits excellent detergent, emulsifying and bactericidal properties. It is of low toxicity and relatively non-irritating to skin and mucous membranes.

The strength of solution usually employed is 1%. The main indications are: pre-operative skin sterilisation; the cleansing and disinfection of wounds and burns; the removal of scabs and crusts in skin diseases such as impetigo and the cleansing and disinfection of hospital vessels and surgical instruments. 'Cetavlon' is also widely used in the first-aid treatment of burns and scalds.

'Cetavlon' powder is issued in containers of 50 and 500 grammes and 2 kilos., and in envelopes containing 5.7 grammes, packed in boxes of 25 and 100.

## NORMAL CONTROL

One injection of Globin Insulin (with Zinc) before breakfast controls the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the ideal — the normal control of blood sugar. 'Wellcome' brand Globin Insulin (with Zinc) — originated and developed at The Wellcome Research Laboratories, Tuckahoe, New York — is supplied in strengths of 40 and 80 units per c.c., each in phials of 5 c.c. Descriptive literature available on request.

*Protein-replacement therapy***HEPOVITE**

A dry granular preparation of malt and enzyme-hydrolysed liver protein, rich in natural vitamins and essential amino-acids.

**COMPOSITION**

(Each 30 grammes contains)

"Protein" (N x 6.25)	15 grm
Carbohydrate (Maltose)	11.4 grm
Vitamin A	500 I.U.
Vitamin D	50 I.U.
Aneurine HCl	1.0 mg
Riboflavin	2.0 mg
Nicotinic acid	6.5 mg
Pantothenic acid	11.3 mg
Pyridoxine	0.32 mg
Biotin	0.065 mg
Folic acid	0.05 mg
Inositol	8.1 mg

Iron, Calcium, Phosphorus are also present.

**DOSAGE**

½ oz. (7 grms) three times daily is sufficient to provide the necessary protein supplement. Hepovite can be taken on a spoon, sprinkled on food or dissolved in milk, fruit-juices or soda-water.

**INDICATIONS**

To restore and maintain the nitrogen balance in the presence of tissue destruction and repair, e.g. burns, injuries and post-operative states. To provide a dietary supplement in all cases of nutritional deficiency, pregnancy, peptic ulcer, ulcerative colitis and the toxæmia of pregnancy.

Hepovite is issued in tins of 5 oz., at 9/- each. Further details application to the Home Medical Department, Speke, Liverpool, 19, or 50, Bartholomew Close, London, E.C.1.

\* Prices apply to Gt. Britain and N. Ireland only and are subject to professional discount.

**SULPHONA-CREAM**

In order that the doctor may have a free choice of bacteriostatic dressings, **SULPHONA-CREAM** is now offered to the medical profession.

**SULPHONA-CREAM** can be used as an ointment, or applied on a sterile spatula direct to a discoloured or injured area, or spread on linen, or oiled silk.

Formula is the same as for the emulsion in **SULPHONA-TULLE** available only on prescription—has had continued success during the past years due to its acceptance and appreciation by doctors as a product based on the latest scientific knowledge.

**SULPHONA-CREAM** is indicated in the treatment of burns and scalds as a primary dressing to prevent infection. It is also successful in the treatment of septic skin lesions of indolent ulcers, and for burns and scalds when infection has already occurred. The dressing when used in combination with **SULPHONA-CREAM** need only be changed infrequently and healing proceeds rapidly without disturbance of new epithelial cells.

**SULPHONA-CREAM** is sold in tubes and is thus maintained sterile and ready for use. The sterility and composition of each batch is controlled by bacteriological and chemical examination.

**Composition**—**SULPHONA-CREAM** contains 10% w/w Sulphanilamide in Paraffin-Lanolin-Water emulsion.

½ oz. tubes 15/- per dozen. 1 lb. jars 15/- each.

Medical Discount 10%. Special prices for hospital quantities.

Subject to the regulations applying to Schedule 4 of the Poisons Act.

## INCREASED PREVALENCE OF HYPERACIDITY

One legacy of war-time strain persists. It is evidenced by the number of patients exhibiting symptoms of gastrointestinal disorder.

The same stress factors of overwork, hurried, irregular meals and the inability to relax completely still prevail.

In such instances, 'Milk of Magnesia' is invaluable in securing rapid control of discomfort. A colloidal suspension of magnesium hydroxide, it soothes the inflamed mucosa, and neutralizes the excess acid, without liberation of gas. Furthermore, its mild laxative action ensures removal of toxic waste products.

'Milk of Magnesia' may be prescribed with confidence equally in the mild case of dyspepsia or the acute ulcer stage where sustained alkaline treatment is essential.

'Milk of Magnesia' contains approximately 8.45% Magnesium Hydroxide in colloidal suspension.

## 'MILK OF MAGNESIA'

## Universities and Colleges

### UNIVERSITY OF LONDON

Foundation Day will be celebrated on Thursday, Nov. 27, and the celebrations will take the form of a dinner followed by a ceremony or the conferment of honorary degrees and a reception.

The Royal Dental Hospital of London, School of Dental Surgery, has been continued as a school of the University until the end of the session 1947-8.

The Semon Lecture for 1947, entitled "The Applied Anatomy and Physiology of the Pharynx and Oesophagus," will be delivered in the lecture hall of the Royal Society of Medicine (1, Wimpole Street, N.W.1) by Mr. E. D. D. Davis on Thursday, Nov. 6, at 5 p.m. The lecture is addressed to students of the University and to others interested in the subject. Admission is free, without ticket.

The British Postgraduate Medical School has been continued as a school of the University until the end of the session 1947-8, or until the British Postgraduate Medical Federation is constituted as a school of the University, whichever period is shorter.

Percy Cyril Claude Garnham, M.D., has been appointed to the readership in Medical Parasitology tenable at the London School of Hygiene and Tropical Medicine, from Oct. 1.

The following have been recognized as teachers of the University in the subjects indicated in parentheses: *London Hospital Medical College*: Mr. R. H. Dobbs, M.D., F.R.C.S. (Children's Diseases); Mr. J. W. S. H. Lindahl, M.Ch., F.R.C.S. (Oto-Rhino-Laryngology). *St. Mary's Hospital Medical School*: Dr. C. Hardwick (Medicine). *Middlesex Hospital Medical School*: Mr. A. J. B. Goldsmith, F.R.C.S. (Ophthalmology); Mr. C. J. B. Murray (Surgery). *St. Mary's Hospital Medical School*: Dr. W. H. Hughes (Pathology (Bacteriology and Immunology)). *University College Hospital Medical School*: Mr. D. N. Matthews, M.Ch., F.R.C.S. (Surgery); Miss Winifred J. Wadge, F.R.C.S. (Oto-Rhino-Laryngology). *King's College Hospital Medical School*: Dr. V. F. Hall (Anaesthetics); Dr. H. A. Magnus (Pathology); Mr. N. S. G. Duxton, F.R.C.S., and Mr. H. L. C. Wood, M.S. (Orthopaedics, in addition to Surgery).

John Duncan MacLennan, M.B.E., M.D., has been awarded an C.I. Research Fellowship of the value of £600 per annum and nable in the first instance for three years for research at the British Postgraduate Medical School on 'the toxæmia of gas ingrene.

### UNIVERSITY OF LEEDS

Among the recently appointed members of the staff of the Faculty of Medicine the following have taken up their appointments at the beginning of the present session: I. G. Davies, M.D., M.R.C.P., P.H., as Professor of Public Health; C. W. Dixon, M.D., D.L.O., C.H., D.P.H., as Lecturer and Chief Assistant in Public Health; A. Divine, M.B., Ch.B., as Senior Administrative Officer, School of Medicine; R. P. Harbord, M.D., D.A., as Reader in Anaesthetics; Harold Petty, F.R.C.S., as Research Fellow in the Surgery of Rheumatism; C. J. Polson, M.D., F.R.C.P., as Professor of Preventive Medicine.

R. Orton, M.D., D.P.M., who has been appointed Senior Lecturer in Psychiatry, will take up his duties before the end of the year. Her appointments are announced as follows: W. J. Allen, M.D., Lecturer in Physiology; D. E. Price, M.B., B.S., Lecturer in Preventive Medicine.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council of the College held on Oct. 9, with Sir Alfred Webb-Johnson, Bt., President, in the chair, J. M. Wyatt was co-opted to the Council as a representative of gynecology and obstetrics and was also appointed to represent the College on the Central Midwives Board.

The Hallett Prize was presented to Dr. Nanalal Jivan Shah (Guy's Hospital Medical School). Mr. Alexander Livingston (Epsom College) was admitted as a Macloghlin Scholar. The award of the Epsom Medal to Surgeon Commander G. H. G. Southwell-Sander, N., was announced.

The President reported a gift of £105 to the Restoration Fund from Dr. Frank Lahay and gifts of silver from Profs. R. V. Bradlaw and H. Stobie in connexion with the inauguration of the Faculty of Dental Surgery.

The general annual report and the annual scientific report of the College were approved.

The following hospitals were recognized in respect of the resident surgical posts required of candidates for the Final Fellowship Examination: Ashford County Hospital, three resident junior house-officers and three surgical registrars for a period of one year; and on Dunstable Hospital, resident surgical officer and senior house-surgeon for one year; Hope Hospital, Salford, assistant resident surgical officer, assistant medical officer in the department of general surgery, and assistant medical officer of the orthopaedic

department; Worcester Royal Infirmary, resident surgical officer and two house-surgeons; Royal Northern Hospital, Inverness, first and second house-surgeons for a further year.

A Diploma in Laryngology and Otology was granted to B. Cohen and a Diploma in Ophthalmic Medicine and Surgery to J. McClement, both jointly with the Royal College of Physicians of London.

### ROYAL COLLEGE OF SURGEONS IN IRELAND

The following have received the Fellowship: D. Boland, D. M. Brooks, J. Bunting, R. A. E. Magee, E. O'Malley, W. J. O'Regan, A. B. Walsh, F. H. Counihan.

## Medical News

### Invalids' Milk Cut

Invalids' priority allowances have been reduced by two-sevenths, so that those entitled to 14 pints of milk weekly receive only 10. The priority allowance of 7 pints weekly for children aged 1 to 5 is reduced to 6 pints. The Ministry of Food attributes the necessity for this to the severity of last winter and the dry summer that followed it. For the first nine months of this year, as compared with last year, the loss amounted to 30 million gallons, and it has been impossible to build up adequate stocks of milk foods for babies.

### Scientific Films

A congress held in Paris on Oct. 2-9 by the Scientific Film Association and the Institut de Cinématographie Scientifique decided to form forthwith an International Scientific Film Association. The Association will be concerned with all aspects of scientific films and an information bureau will shortly be established in Paris. The congress next year will be held in Britain in October. A provisional constitution for this organization has been agreed by delegates from France, Great Britain, South Africa, New Zealand, Canada, Australia, Malaya, Netherlands, Belgium, Switzerland, Poland, Yugoslavia, Czechoslovakia, Luxemburg, Monaco, Austria, Brazil, Peru, Mexico, China, Denmark, and Ecuador.

### Road Accidents

A War Office inquiry into road accidents involving Servicemen found that 40% occurred on straight roads away from a junction. An investigation into accident proneness, as suggested by the Committee on Road Safety in their Report, referred to in our leading article last week (p. 618), is being carried out by the Department of Scientific and Industrial Research. One-third of all the accidents investigated occurred when one vehicle was overtaking another, moving or stationary, and a stationary vehicle was involved in 20% of the cases.

### Infantile Paralysis

The disease was first described in 1789 by Underwood, a London physician, said Prof. H. J. Seddon, speaking on infantile paralysis at the Royal Institute of Public Health and Hygiene on Oct. 15. The first recorded epidemic occurred in St. Helena early in the 19th century. He compared the present epidemic with road accidents, most of which were preventable, and said that it was almost trivial in the amount of incapacity that it had caused. Some of the handicaps in the investigation of the disease were the expense and difficulty in using monkeys as experimental animals, the unsuitability of rodents generally, and the absence of any diagnostic test for the presence of the virus or the disease itself. This was the time of year when fresh fruit and vegetables were consumed in the greatest quantity, yet it had not been possible to demonstrate any definite connexion between this seasonal change in diet and the incidence of the disease. The relative immunity of adults was due to the fact that, without knowing it, they had already had a mild non-paralytic attack of the disease. There were two important general preventive measures: the avoidance of physical strain and of overcrowding. There was no specific remedy for the established disease; the results of serum treatment had been equivocal, and none of the new chemotherapeutic agents had proved effective.

### Bisset Hawkins Medal

The Bisset Hawkins Medal was presented to Dr. C. H. Andrewes at the Royal College of Physicians on Oct. 18 for his research into typhus and influenza.

### Dr. Kenneth Cowan

For health reasons Dr. Kenneth Cowan is not taking up his appointment as Senior Administrative Medical Officer to the South-west Metropolitan Regional Hospital Board, which was announced in the *Journal* of Oct. 11 (p. 597). He will remain as county medical officer of health for Gloucestershire.

**Medical Benefit Society**

The thirty-ninth Annual Meeting of the Medical Benefit Society for the East and North Ridings of the County of York (including the City of York) was held by courtesy of the York Medical Society in their library at York on Sept. 23, Dr. Ritchie Rodger, J.P., presiding. After approving the minutes of the Annual Meeting of 1946 the Annual Report for the year 1946-7, including that of the Hon. Treasurer, was received and adopted. From the latter it appeared that £107 5s. had been granted in relief. With a current balance of £362 the financial position was considered very satisfactory. The officers elected for the coming year were Mr. R. B. Blair (Hull) as President, Dr. G. F. Longbottom (Middlesbrough) as Vice-President, Dr. M. Jacobs as Hon. Secretary, Dr. N. T. Whitehead as Hon. Treasurer, with Messrs. Harold Locking and Co. as auditors. Nine new members were elected. There were no further applications for relief.

**Highway First Aid**

The July number of the British Red Cross Society's *News Survey* reviews Red Cross activities throughout the world and records a speech by Air Marshal Sir Harold Whittingham, the Society's medical adviser, on first-aid services on the highway. He made the interesting point that first-aid posts should be transportable, because the danger spot of to-day might cease to be one in a year or so, owing to road improvements. The sentry-box was the most suitable type of first-aid post on account of its portability and relatively low cost.

**Wills**

Dr. Arthur Whitfield, formerly professor of dermatology in King's College, London, left £48,576. Dr. Arthur Frederick Bernard Shaw, formerly professor of pathology at the University of Durham, left £12,600. Mr. William Gough, formerly professor of gynaecology at the University of Leeds, left £42,236. Mr. Cecil Banting, M.S., F.R.C.S., of Thanet, Kent, formerly an underwriting member of Lloyd's, left £186,971. Mrs. Ellen Matilda Cooper, of Birehington-on-Sea, who died on April 17, aged 99, widow of Dr. James Cooper, left £109,052, and bequeathed £10,000 to St. Bartholomew's Hospital to found research scholarships. Dr. Samuel Allan Shiaeh, of Elgin, chairman and managing director of Macallan Glenlivet, Ltd., owners of Macallan Distillery, Speyside, left £87,176.

**COMING EVENTS****Discovery of Chloroform Anaesthesia**

The centenary of Sir James Young Simpson's discovery of chloroform anaesthesia will be celebrated at Edinburgh on Nov. 4. Prof. R. R. Macintosh, Dr. D. S. Middleton, and Dr. John Gillies will read papers on the use of chloroform at present, at a meeting to be held at 9.30 a.m. in the Lecture Room of the Surgery Department, University New Buildings, Teviot Place. At 12 noon in the Upper Library, Old College, the honorary degree of Doctor of Laws will be conferred on Dr. H. W. Featherstone, O.B.E., and Dr. T. B. Simpson, K.C. After lunch at 12.45 in the Senate Hall, College, a reception will be held at 3.30 in the Upper Library, at 3.45 Dr. Douglas Guthrie will deliver an address. Tea is o'clock. A display of relics will be on view in the Upper Library from Nov. 3 to Nov. 7.

**Middlesex County Medical Society**

The next general meeting of the Middlesex County Medical Society will be held at West Middlesex County Hospital, Isleworth, on Tuesday, Oct. 28, at 3 p.m., when there will be clinical demonstrations of surgical, medical, obstetrical, etc., cases.

**Society of Chemical Industry**

A meeting of the Nutrition Panel of the Food Group of the Society of Chemical Industry will be held at the Chemical Society's rooms (Burlington House, Piccadilly, London, W.) on Wednesday, Oct. 29, at 6.30 p.m., when a paper on "Food and Cancer" will be presented by Prof. A. Haddow and Dr. L. A. Elson. All members of the Food Group are invited to attend the meeting and members may introduce friends in person.

**Care of Old People**

The Bristol Council of Social Service and the Bristol and District Divisional Hospitals Council have arranged a conference on the Care of Old People to be held on Wednesday, Oct. 29, from 2.30 p.m. to 5.15 p.m. in the Reception Room at the University of Bristol. Drs. E. L. Sturdee and Marjory Warren will speak on "Medical Needs," and Miss D. Ramsey, M.A., Secretary to the National Old People's Welfare Committee of the National Council of Social Service, will speak on the "Social Needs." After a discussion there will be a summing-up by Dr. R. H. Parry.

**Central Council for the Care of Cripples**

A general meeting of the Central Council for the Care of Cripples will be held on Friday, Oct. 31, at 2.30 p.m., in the Lecture Theatre of the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., when Dr. Charles Hill will address the meeting. The Earl of Dudley, M.C., will be in the chair.

**Royal Dental Hospital of London**

The annual clinical "At Home" of the Royal Dental Hospital of London School of Dental Surgery (University of London) will be held at the hospital, 32, Leicester Square, W.C., on Saturday, Nov. 22, from 9.30 a.m. to 5 p.m. The annual dinner will not be held this year.

**Refresher Courses in Tuberculosis**

The Northern Ireland Branch of the National Association for the Prevention of Tuberculosis will hold two refresher courses as follows: (1) "Recent Advances in Tuberculosis," for tuberculosis officers and medical practitioners (fee, 3 gns.; fourth and final year medical students free), to be held at the Midwifery Theatre, Queen's University, Belfast, on Nov. 26-29. (2) "The New Administrative Approach to Tuberculosis," for health visitors, almoners, and social workers (fee, 10s.), to be held at Bryson House, Bedford Street, Belfast, on Nov. 27-29.

**Clinical Biology at Paris**

The French Society of Clinical Biology will hold the first International Congress of Clinical Biology at Paris on Nov. 20-22 under the presidency of Prof. Polonovski. Persons interested in medical biology are invited to participate. The subscription is 300 francs, and those who wish to attend a banquet being held on Nov. 21 are required to pay an additional 900 francs. Particulars may be obtained from the Secretary General, Dr. Durupt, 20, rue de la Pompe, Paris.

**William Blair-Bell Memorial Lectures**

The Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, London, W.) announces that the William Blair-Bell Memorial Lectures for 1947 will be delivered in the College House on Nov. 14, at 5 p.m., and on Jan. 23, 1948, at 5 p.m. The first lecture will be delivered by Dr. D. J. MacRae, on "Heart Disease in Pregnancy," and the second lecture by Dr. Stanley A. Way on "Primary Carcinoma of the Vagina." All medical practitioners interested in the subjects are invited to attend the lectures, but admission is by ticket only, obtainable from the secretary. Tickets will be allotted in order of application, and applicants are asked to indicate for which lecture tickets are required.

**Harben Lectures**

Prof. Edgar D. Adrian, O.M., F.R.S., M.D., F.R.C.P., professor of physiology, Trinity College, Cambridge, has accepted the invitation of the Royal Institute of Public Health and Hygiene to be the Harben Lecturer for 1947. His subject is "The Organization of the Nervous System" and the lectures will be delivered at the Institute (28, Portland Place, London, W.) on Monday, Tuesday, and Wednesday, Dec. 8, 9, and 10, at 3 p.m. each day. Admission is free, without ticket. Seats may be reserved upon application to the secretary of the Institute.

**SOCIETIES AND LECTURES**

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Arnott Demonstrations by Mr. H. F. Lunn, Monday, Oct. 27, 5 p.m. The Applied Anatomy of Testicular Descent; Tuesday, Oct. 28, 5 p.m. The Cerebral Cortex and the Status of Man; Wednesday, Oct. 29, 5 p.m. Moynihan Lecture by Mr. W. R. Douglas: The Surgical Treatment of Metastatic Carcinoma of the Cervical Glands; Thursday, Oct. 30, 5 p.m. Imperial Cancer Research Fund Lecture by Dr. James Craigie: Viruses, Self-reproducing Substances and Tumours.

**ROYAL SOCIETY OF MEDICINE**

Section of Odontology.—Monday, Oct. 27, 5.30 p.m. Presidential Address by Prof. H. Humphreys: Dental Education.

Section of Medicine.—Tuesday, Oct. 28, 8 p.m. Discussion: Chemotherapy in Malignant Diseases. Openers: Prof. A. Haddow, Drs. Edith Paterson, E. Boyland, J. F. Wilkinson, Jean M. Watkinson, O. H. Warwick, and Mr. E. W. Riches.

BIOCHEMICAL SOCIETY.—At St. Thomas's Hospital Medical School, Albert Embankment, Westminster Bridge, London, S.E., Friday, Oct. 31, 2.15 p.m. Communications and Demonstrations.

BRITISH INSTITUTE OF PHILOSOPHY.—At University Hall, 14, Gordon Square, London, W.C., Friday, Oct. 31, 5.15 p.m. Mr. W. J. H. Sprott: Psychology and the Moral Problems of Our Time.

DEWSBURY: STAINCLIFFE COUNTY HOSPITAL.—Thursday, Oct. 30, 8 p.m. Mr. W. R. Henderson: Some Aspects of Neurological Surgery.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At Leeds General Infirmary, Friday, Oct. 31, 8.30 p.m. Sir Archibald McIndoe: Surgery of the Burnt Hand.

LONDON: UNIVERSITY COLLEGE, Gower Street, W.C.—Tuesday, Oct. 28, 5.15 p.m. Dr. Bernard Katz: Physical and Chemical Signs of Nerve Activity; Wednesday, Oct. 29, 5 p.m. Dr. M. H. Pirrenne: Physiological Mechanisms of Vision.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—Monday, Oct. 27, 8.30 p.m. Discussion: Treatment of Peptic Ulcer. To be introduced by Dr. A. H. Douthwaite and Mr. Norman Tanner.

PADDINGTON MEDICAL SOCIETY.—At St. Mary's Hospital, Paddington, W., Tuesday, Oct. 28, 9 p.m. Film on the treatment of varicose conditions and their complications, to be introduced by Mr. A. Dickson Wright. All medical practitioners are invited to attend the meeting.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W.—Wednesday, Oct. 29, 3.30 p.m. Dr. W. G. S. Pepper: The Doctor in Industry (illustrated).

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—Friday, Oct. 31, 8 p.m. Address by Prof. W. E. Le Gros Clark: The Role of the Anatomist in the Study of Sensory Functions.

SOCIALIST MEDICAL ASSOCIATION.—At Denison House, 296, Vauxhall Bridge Road, S.W., Friday, Oct. 31, 7.30 p.m. Dr. J. E. McCartney: Some Impressions of American Laboratories (illustrated).

## POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At West Medical Lecture Theatre, Edinburgh Royal Infirmary, Tuesday, Oct. 28, 5 p.m. Mr. J. M. Graham: Obstructive Dyspnoea.

EDINBURGH ROYAL INFIRMARY.—Thursday, Oct. 30, 4.30 p.m. Honyman Gillespie Lecture by Dr. W. Ritchie Russell: Traumatic Amnesia.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Tuesday, Oct. 28, 5 p.m. Dr. Muende: Pathological Demonstrations. Thursday, Oct. 30, 5 p.m. Dr. H. MacCormac: Occupational Dermatitis.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, London, W.C.—Tuesday, Oct. 28, 4.30 p.m. Mr. Terence Cawthorne: Surgical Treatment of Deafness.

LONDON CHEST HOSPITAL, Victoria Park, E.—Friday, Oct. 31, 5 p.m. Dr. N. Lloyd Rusby: Recent Advances in the Diagnosis of Pulmonary Tuberculosis.

The Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, London, W.) has arranged a postgraduate course of advanced lectures for those studying the special practice of obstetrics and gynaecology to be given in the College House from Monday, Nov. 17, to Friday, Nov. 21, at 5 p.m., both dates inclusive. The fee or the course is £2 2s. (10s. 6d. for a single lecture). A small number of tickets will be available free of charge to Fellows and members of the College and will be allotted in order of application. There will be no admission without tickets, which are obtainable from the secretary.

## APPOINTMENTS

As a result of a reallocation of duties, the Secretary of State for Scotland has appointed Mr. N. D. Walker of the Department of Health for Scotland to be a member of the Central Midwives Board for Scotland in place of Mr. T. A. Greig of that department.

Prof. F. E. Tylecote, M.D., F.R.C.P., J.P., has been elected a member of the Central Midwives Board, on the nomination of the Association of Municipal Corporations.

Sir Alexander Macgregor, M.D., LL.D., has accepted the Secretary of State for Scotland's invitation to become chairman of the Western Regional Hospital Board in place of Prof. E. P. Cathcart, M.D., R.S., who asked to be relieved of the appointment on account of health.

Sir Alexander Macgregor was medical officer of health for the City of Glasgow from 1925 until his retirement in 1946. He is at present chairman of the Scientific Advisory Committee.

James Barclay Ewen, M.D., D.P.H., has been appointed Senior Administrative Medical Officer of the East Anglian Regional Hospital Board.

Dr. Ewen is Principal Assistant Medical Officer (Hospitals Section) of the Middlesex County Council.

William Alexander Ramsay, M.D., has been appointed Senior Administrative Medical Officer to the Sheffield Regional Hospital Board.

For the past fourteen years Dr. Ramsay has been medical superintendent of the Imperial Hospital, Manchester.

Charles Lindsay Elder, M.B., Ch.B., D.P.H., has been appointed Medical Officer of Health for Middlesbrough.

BUCKLEY, WILLIAM, M.A., M.B., B.Chir., F.R.C.S., Assistant Thoracic Surgeon, Nottinghamshire County Council and Nottingham City Council.

CANADIAN RED CROSS MEMORIAL HOSPITAL, Taplow, Maidenhead, Berks.—Director of Research Unit (Juvenile Rheumatism): Eric Bywaters, M.B., M.R.C.P. Director of Department of Pathology: L. E. Glynn, M.D., M.R.C.P.

JOHNSON, H. D., M.B., B.Ch., F.R.C.S., Honorary Assistant Surgeon, Royal Free Hospital, Gray's Inn Road, London, W.C.

NEWBOLD, J. C., M.A., M.B., B.Chir., F.R.C.S., M.R.C.O.G., Honorary Assistant Obstetrician and Gynaecologist, Royal Hospital, Wolverhampton.

## BIRTHS, MARRIAGES, AND DEATHS

### BIRTHS

BARTON.—On Oct. 4, 1947, at Musgrave Park, Taunton, to Paddy (née Symmers), wife of Dr. Charles Barton, M.B., a daughter—Jane. A sister for Moyra and Ruth.

COLE.—On Oct. 11, 1947, at Trieste, to Kathleen (née Collins), wife of Major P. L. G. Cole, R.A.M.C., a daughter—Jane Ingrid Peirson.

DICKSON.—On Oct. 17, 1947, at Ardcoape Nursing Home, Nunthorpe, Middlesbrough, to Betty, wife of David C. Dickson, F.R.C.S. (Edn.), Upsall Grange, Nunthorpe, a son.

HAIR.—On Oct. 2, 1947, to Doreen (née Bennett), wife of John A. G. Hair, M.B., B.S., D.M.R.E., White Cottage, Camborne, a son.

HALSTEAD.—On Oct. 16, 1947, at Bradford, to Margaret and John Halstead, a son.

PURCE.—On Oct. 10, 1947, at the Haywood Hospital, Burslem, to Eleanor (née Frankel), wife of Dr. James Purce, of The Lodge, Basford, Stoke-on-Trent, a daughter.

REWELL.—On Oct. 4, 1947, at Nuffield House, Guy's Hospital, to Betty Jean (née Willis) and Dr. R. E. Rewell, a daughter—Susan Jane.

WILLATT.—On Oct. 14, 1947, at Bognor Regis, to Dr. Ruth (née Evershed), wife of Dr. J. D. Willatt, a son.

### DEATHS

AYLEN.—On Oct. 12, 1947, at Angmering-on-Sea, Ernest Vaughan Aylen, D.S.O., M.R.C.S., L.R.C.P. (Lieutenant-Colonel, R.A.M.C., Ret.), aged 70.

BEATTY.—On Oct. 16, 1947, at 49, Stafford Road, Weston-super-Mare, James Beatty, M.D., M.R.C.P.

BROWN.—On Oct. 2, 1947, at Lubwa, Chinsali, N. Rhodesia, Rev. David M. Brown, M.D.

DOBSON.—On Oct. 2, 1947, at 75, Liscard Road, Wallasey, Cheshire, Robert Thornley Dobson, M.B., Ch.B.

DODDS.—On Oct. 15, 1947, at Strathaird, Easter Belmont Road, Edinburgh, Mary Janet Dodds, O.B.E., L.R.C.P. & S.Ed.

HOUGHTON.—On Oct. 11, 1947, at Eastbourne, Murtaugh James Houghton, M.R.C.S., L.R.C.P.

KIRK.—On Oct. 9, 1947, at 167, Coniscliffe Road, Darlington, Charles Joseph Kirk, M.B., Ch.B.

LANO.—On Oct. 11, 1947, John Murgatroyd Lano, M.R.C.S., L.R.C.P., of 29, St. Andrew's Villas, Bradford, aged 59.

MACGILLIVRAY OF MACGILLIVRAY.—On Oct. 15, 1947, at Crail, Fife, Angus, MacGillivray of MacGillivray, T.D., C.M., M.D., D.Sc., LL.D.

PEARSON.—Harry Linden Pearson, M.B., Ch.B., of St. Anne's-on-Sea.

PICKERING-PICK.—On Oct. 14, 1947, at Combe Lodge, Chambercombe Park, Ilfracombe, Lawrence Pickering-Pick, M.R.C.S., L.R.C.P.

QUINE.—On Sept. 22, 1947, Albert Edward Quine, F.R.C.S. of Whitstable.

RAWES.—On Oct. 8, 1947, at his home, Charles Kinsman Rawes, M.B., Ch.B., aged 81.

SHARPLES.—On Oct. 11, 1947, at Buxton Cottage, Buxton Lane, Caterham, Surrey, Moses William Sharples, M.B., Ch.B., aged 78.

SMITH.—On Oct. 13, 1947, at Woking, Surrey, Gilbert Johnstoo Smith, M.B., Ch.B. (I.M.S., Ret.), aged 49.

WARREN.—On Oct. 11, 1947, Herbert Henry Warren, M.B., Ch.B., of 24, Goldsmith Avenue, Southsea.

WESTON.—On Oct. 11, 1947, William Gordon Weston, M.B., Ch.B., of 37, Stanhope Gardens, London, S.W., aged 67.

WHITE.—On Oct. 11, 1947, at the County Hospital, Ashton-under-Lyne, Leonard White, M.R.C.S., L.R.C.P.

## EPIDEMIOLOGICAL NOTES

### Poliomyelitis

The decline in the notifications of poliomyelitis 338 (402) and of polio-encephalitis 26 (27) continued in the week ending Oct. 11. Figures for the previous week are shown in parentheses. In London Administrative County notifications were: poliomyelitis 31 (38), polio-encephalitis 3 (3).

There were substantial declines in the notifications of poliomyelitis in Bedfordshire 3 (10), Durham 5 (14), Essex 7 (24), Lancashire 43 (64), Middlesex 17 (28), and Yorkshire West Riding 11 (18); the most important rise was in Derbyshire 13 (5).

Two large-scale inquiries are known to be in progress: one from the Ministry of Health derives its information from certain general and infectious diseases hospitals throughout the country and aims at securing more accurate estimates of the fatality and severity of the disease in the present epidemic; the other, organized by Dr. A. M. McFarlan and other members of the staff of the Public Health Laboratory Service, will be more comprehensive and is concerned with the epidemiology of the disease in selected areas. Although these two inquiries are

separate and should not be confused it will be found that so far as hospitals are concerned the method of tabulation of cases is almost the same for both.

### Cholera in Egypt

Deaths from cholera in the present epidemic in Egypt now number well over 3,000. For the first three weeks of the epidemic the figures given officially each day listed deaths, positive cases, and suspected cases; an abrupt rise in incidence was noted a fortnight ago, when the figures were:

	Deaths	Positive Cases	Suspected Cases
Oct. 10 .. ..	68	141	170
" 11 .. ..	69	180	132
" 12 .. ..	112	216	150
" 13 .. ..	114	238	114
" 14 .. ..	123	358	

Since Oct. 14 "suspected" cases have not been recorded, and the deaths on the four subsequent days were 175, 308, 247, and 279, with between 600 and 700 positive cases each day. On Oct. 20 there were 561 deaths, and 1,022 new cases were notified.

These figures are probably minimal. Nokrashy Pasha, the Prime Minister, has stated that the authorities are being hampered by the failure to report cases. It appears that Alexandria is still free from infection. Cairo has relatively few cases, and the provinces most affected are Sharkia and Dakahlia.

According to the *Egyptian Mail*, credits allotted to the anti-cholera campaign now total £E.1,000,000. The Royal Egyptian Air Force is continuing D.D.T. spraying of certain overcrowded districts in Cairo, and more than 12,000 houses have been individually sprayed with D.D.T. in kerosene. Movement across the Nile has been restricted; railway travel is curtailed, and arrangements are in hand to increase the number of persons inoculated daily to 500,000.

### Cholera and Dysentery in Punjab

In the week ending Oct. 14, according to recent Press reports, 593 people died from cholera and dysentery in East Punjab, as compared with 663 in the preceding week. This is said to correspond to a fatality rate of some 25%.

### Discussion of Table

In *England and Wales* an increase occurred in the notifications of scarlet fever 206, measles 117, acute pneumonia 73, diphtheria 34, cerebrospinal fever 16, and dysentery 10, while decreases were reported in the incidence of acute poliomyelitis 39, whooping-cough 19, and typhoid fever 10.

A small increase in the incidence of scarlet fever was recorded in most areas; the largest rise was Lancashire 78. The notifications of this disease were two and a half times the number recorded five weeks ago.

There was a slight general rise in the notifications of diphtheria; the largest increase was in Durham, where the number of cases rose from 7 to 20. There were no large changes in the local returns of whooping-cough. A small rise in the notifications of measles was recorded in most areas; the largest rise was in Lincolnshire 45.

Of the 12 cases of typhoid 8 were notified in Middlesex, Harrow U.D., where 6 cases appeared in the preceding week. An outbreak of dysentery involving 14 persons was recorded in Durham, South Shields C.B. The only other large returns of dysentery were Lancashire 17 and Surrey 10.

In *Scotland* an increase in incidence was reported for measles 43, scarlet fever 34, and diphtheria 18; a decrease was recorded for poliomyelitis 15. The increase in cases of diphtheria was contributed by Glasgow with a rise from 15 to 29. A general rise in the incidence of scarlet fever occurred throughout the Western area. There were no notable fluctuations in the trend of poliomyelitis.

In *Eire* the chief feature of the returns was an increase of 23 in the notifications of scarlet fever. Notifications of diarrhoea and enteritis remained at the level of the preceding week, while the incidence of measles increased by 13 and the number of cases of diphtheria fell by 7.

In *Northern Ireland* 14 cases of poliomyelitis were notified, compared with 1 in the preceding week. The notifications of scarlet fever increased by 10.

### Week Ending October 11

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,316, whooping-cough 1,043, diphtheria 201, measles 1,639, acute pneumonia 403, cerebrospinal fever 45, acute poliomyelitis 338, acute poliomyelitis 26, dysentery 67, paratyphoid 12, and typhoid 8.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 4.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Expression of Placenta

**Q.**—At the Ronnda Bicentenary Congress it was urged that Credé's manœuvre for expressing the placenta should be abandoned. What procedure is now advocated when the placenta is still in utero thirty minutes after delivery, or when there is bleeding due to partial separation of the placenta? And, further, do obstetricians condemn squeezing the uterus to expel blood-clot where there is a steady loss of blood after expulsion of the placenta and the uterus is well contracted?

**A.**—The abandonment of Credé's manœuvre has long been advocated by some authorities, and statements to this effect, touched on in no uncertain terms, are to be found in standard works on midwifery, such as *Principles and Practice of Obstetrics*, by J. B. DeLee and J. P. Greenhill, 1947. All are agreed that the squeezing of the uterus which is involved is conducive to shock, and some will say that it rarely achieves its object—separation of the placenta from the uterine wall. The obvious alternative to Credé's manœuvre is to remove the placenta manually. Whether in the absence of bleeding it is justifiable to do this at the end of half an hour is open to question, but it should certainly be seriously considered at the end of one hour, and at any time before then if the patient's pulse rate begins to rise or she shows signs of impending shock. An alternative when there is no emergency is possibly to inject the cord with saline, although this appears to be effective in only a few cases. If, when the placenta is still partly adherent, haemorrhage occurs, immediate action must be taken, and the alternatives are either to remove the placenta manually or to give an intravenous injection of ergometrine or an intrauterine injection of oxytocin. This was discussed at some length in a reply to a question which appeared in the *Journal* of Aug. 2 (p. 195) and in a letter from Prof. Chassar Moir (Aug. 23, p. 309). The latter pointed out that the intravenous dose of ergometrine should never exceed 0.25 mg. The writer, however, has worked in a hospital where 0.5 mg., and even 1 mg., of ergometrine has been given intravenously almost as a routine by the medical staff for nearly two years, and no member of the medical or nursing staff has ever seen any reaction or ill effect attributable to the drug. It must be admitted, however, that many patients were partly or wholly under the influence of an anaesthetic at the time and so were incapable of recording their sensations. Whether such a large dose is really necessary is debatable, but in emergency it can certainly be given with safety. There is still some difference of opinion as to whether manual removal is preferable to an oxytocic drug, but if the surroundings are unfavourable there is much to be said for the latter. Gentle and cautious squeezing of blood-clot from the uterus would probably not be condemned by most authorities; the amount of force required is much less than in the case of an adherent placenta. Blood-clots, however, cause bleeding by interfering with retraction and contraction of the uterus, and if the uterus is firmly contracted any clot which is expressed comes from the cervix and vagina—where it is doing no harm. When the uterus is relaxing and blood is collecting within, the administration of an oxytocic drug by the intravenous or intrauterine route should be just as efficient as manual squeezing, and possibly more so.

### Marital Phthisis

**Q.**—Is there any evidence to suggest that there is a higher incidence of pulmonary tuberculosis among the consorts of sputum-positive cases of tuberculosis than in the corresponding age and sex groups of the population at large? What literature on this subject can you recommend?

**A.**—So many conflicting reports have been published on this subject that it is impossible to be dogmatic. Fishberg, after quoting many references from the previous literature together

with some of his own figures, concludes that the incidence of marital phthisis is about 3%—amazingly small when the intimacy of contact is considered. On the other hand, Opie and McPhedran, in a study of 133 married couples, found that 20% of the consorts of sputum-positive individuals developed clinically manifest disease. On the whole the evidence shows that the incidence of pulmonary tuberculosis is higher in the consorts of tuberculous individuals than in those of the non-tuberculous. But it is only slightly higher, and there is much evidence to show that prolonged exposure is necessary to produce infection and that the infection which develops tends to be of a benign type. For further references to the literature on this subject consult Fishberg, M., *Pulmonary Tuberculosis*, Kimpton, London, 1932; Opie, E. L., and McPhedran, F. M., *Arch. intern. Med.*, 1932, 50, 945; and Rich, A. R., *The Pathogenesis of Pulmonary Tuberculosis*, Thomas, Springfield, Illinois, 1946.

### Polyuria

**Q.**—What are the probable causes of polyuria in a male, aged 66, with no glycosuria and no physical signs of enlarged prostate, stone, or nephritis? The patient is fairly healthy, but has symptoms of an apparently over-active vagus, with dizziness after rapid change of posture or on climbing stairs. These symptoms have persisted for some years. Blood pressure 140/92 mm., urine normal (except for the quantity and consequent frequency), and haemoglobin 92%. Is it usual for a vagus disturbance to be repeated in the great splanchnic nerve, and, if so, how is the increased production of urine mechanically brought about? Are there any known causes for an unusual vagus activity?

**A.**—It is essential to obtain precise measurements of the daily urinary volume when patients claim to be passing a greater quantity than normal. In most instances their claims are ill founded, and increased frequency of micturition alone is present. If there is a true increase in urinary volume, the quantity of fluid drunk during the day should be measured; some patients acquire habits of drinking amounts of water in excess of their needs. With the exceptions of diabetes mellitus and diabetes insipidus, all other causes of polyuria depend upon impaired kidneys being unable to elaborate a normally concentrated urine. Diabetes insipidus is improbable in a man of 66, particularly as the condition seems to have been static for several years. If he can pass urine with a specific gravity above 1020, significant renal disease is unlikely. In diabetes insipidus a normal specific gravity can be achieved after injection of "pitressin." Investigation along these lines would be required before the question could be answered more exactly.

The cardiovascular symptoms noted are common in those past middle age with some arterial degeneration; they depend upon the diminished readiness with which arterial pressure adjusts itself to postural changes. It is doubtful whether vagus activity plays much part.

### Swabbing Maternity Ward Attendants

**Q.**—What are the generally accepted rules for the swabbing of throats of the attendants of a maternity ward? How often should it be done, and should both nose and throat be swabbed? In addition to *Str. pyogenes* Group A, are any other of the haemolytic streptococci pathogenic? Are any of the staphylococci regarded as pathogenic, especially with regard to pemphigus of the newborn? In the case of a nurse carrying pathogenic streptococci in her throat, how many negative swabs should be asked for, and over what period, before she can work in a maternity ward?

**A.**—Practice varies considerably, and there has been a tendency to relax such precautions since chemotherapy has so greatly lessened the dangers of puerperal fever. Strict control demands swabbing of all personnel before employment, at regular intervals thereafter (every two or three months), and following any upper respiratory tract infection. Nasal swabs as well as throat swabs are necessary; the nasal carrier is much the more dangerous. Although puerperal fever, and even septicaemia, are occasionally due to streptococci of other Lancefield groups than A, it is usual to disregard carriers of any but Group A, since this causes the great majority of serious cases of puerperal fever and is almost always concerned when

the disease occurs in epidemic form. The significance of a negative finding in a swab from a previous streptococcus carrier varies with the degree of skill with which the swab is taken and examined, and with the nature of the carrier state—whether symptomless or accompanied by catarrh or tonsillar hypertrophy. In the absence of any visible lesion a single competent negative swab should suffice.

*Staphylococcus pyogenes aureus* (recognized as pathogenic by the coagulase test) is the cause of pemphigus in infants, and multiple nasal carriers among maternity home staffs are its usual source. This subject was exhaustively dealt with in the *Journal* recently (see article by V. D. Allison and Betty C. Hobbs, July 5, p. 1).

### Over-possessive Women

**Q.**—Is there any recognized psychosis or neurosis which corresponds to the ancient idea of "possession by evil spirits"? Having lately come across more than one pathologically possessive woman, I am tempted to formulate the following generalization: "A possessive woman is a woman possessed." In extreme forms the condition would seem fraught with potential evil both to the patient and to those about her.

**A.**—Under "possession by evil spirits" the ancients must have understood a number of different syndromes, which certainly included epilepsy and hysteria, and probably others such as schizophrenia, mania, and melancholia. No modern concept exactly corresponds. It is true that the over-possessive woman can wreak havoc with the lives of others, especially husband and children. She is nearly always enabled to do so by meeting inadequate resistance from those who are "possessed." Her victims are commonly persuaded of the justice of her claims, but much may often be done by the trusted medical adviser to induce a healthier and more realistic attitude. He is in a particularly favourable position to do so if, as is often the case, she maintains her claims by representing herself as an invalid. It is rare that the "disease" is one of a single person; more usually it is a disordered relationship between two or several persons. Despite the malignant effects of such disorders, a psychotherapeutic attack is often possible.

### Chronic Prostatic Infection

**Q.**—While in the Forces a male aged 24 years contracted a *Bacterium coli* urinary infection, starting with orchitis. No history of V.D. or risk. He has spent months in hospital, and has now been discharged as incurable on sulphathiazole 0.5 g. thrice daily. He has been told that the infection is in the prostate and surgical removal might be the only cure. Shortly after stopping the drug the urine becomes foul and the patient feels ill. Can he with impunity continue to take the recommended dose of sulphathiazole indefinitely, and what alternative treatment do you suggest?

**A.**—It is a little pessimistic to regard a persistent infection of the prostate as being incurable. There are a few cases only which require surgical treatment in the way of perineal drainage for an abscess cavity in the parenchyma of the prostate. The great majority of such cases finally clear up with prolonged courses of prostatic massage, posterior irrigation, and the use of the sulphonamides. Sulphathiazole should not, of course, be continued indefinitely, but in separate courses of treatment resumed at intervals.

### Vaccination of a Nursing Mother

**Q.**—If a nursing mother is vaccinated, what effects may this have on the child? Recently I vaccinated a mother, and within a week the baby had thirty or forty papules not unlike those of chicken-pox on its body. The mother blamed the vaccination.

**A.**—It is probable that following the development of immunity as a result of vaccination of the mother there will be some passive transfer of antibody to the infant. It would be possible for a vaccinated mother to infect her child with vaccinia as soon as a lesion appeared at the site of vaccination. The diagnosis of vaccinia in the child (or any vaccinated subject) can be readily confirmed in a virus laboratory by inoculation of material on to the chorio-allantoic membrane of the developing chick embryo.

### Sterilization of Syringes and Specula

**Q.**—Is it possible to sterilize a spinal needle satisfactorily without an autoclave? What is the best solution for sterilization by prolonged immersion of syringes and specula for ordinary surgery use? I find that liq. borac. et formaldehyde (N.W.F.) ruins the hands if it touches them; and 5% liq. chloroxylenol in surgical spirit forms a most adherent and obstinate precipitate.

**A.**—The best method is to place in a dry oven at 150°C. for 1 hour. A less satisfactory alternative, but far better than the use of chemicals and subsequent rinsing in water, is boiling. A Record syringe cannot be sterilized chemically (for authority for this statement and general instructions on the subject see "The Sterilization, Use, and Care of Syringes," Medical Research Council War Memorandum No. 15, H.M.S.O., 4d.). A speculum should not be so difficult to sterilize, and could be freed of ordinary bacteria by any efficient disinfectant solution, including either of those mentioned, 2% lysol, or spirit. Disinfectants should not be condemned for such a purpose because they affect the skin; articles should be removed from them with forceps. Needless to say, for the patient's sake they need rinsing before use, and all such methods, properly carried out, are really more troublesome than boiling.

### NOTES AND COMMENTS

**Short-stay Hostel for the Aged and Infirm.**—The old and infirm are often nursed at home by their own relatives. Old people who are becoming "difficult" may be more exacting in their demands on relatives than they would be to strangers or nurses. A recent and helpful development in connexion with this recurrent problem is the provision by the Red Cross of a hostel where elderly men and women, ambulant or bedridden, can stay for a fortnight or more, while their relatives have a rest or a holiday. Their own general practitioners can visit them as often as they wish, and their own callers may come on any afternoon, and on two evenings a week. The house, a gift to the Red Cross, is of moderate size, with a fairly large garden, a lawn, and some fine trees. There are pleasant rooms, airy and sunny, with wards on the ground floor containing six beds apiece, and a comfortably furnished sitting-room with a wireless.

A fully qualified sister is in charge, with four helpers for day duty, and at night there are three on the premises, of whom one is a qualified nurse. In this hostel none of the staff lives in, but this is not a feature which need necessarily be copied elsewhere. At the same time it should be realized that many types of hospital, hostel, and institution are finding that the employment of non-resident staff is the only answer to the problem of recruitment. The running cost of this hostel varies from time to time, but it has usually worked out at rather more than £4 per head a week, a moderate amount compared to the maintenance cost of hospitals. Visitors usually pay £3 10s. a week, and the balance is found by the Red Cross. Schemes of this kind are obviously deserving of support, and it may be that every county should set up some similar scheme.

**Correction.**—Owing to a printer's error the name of Mr. Keit Vartan was unfortunately misspelt in the review of *The 1946 Year Book of Obstetrics and Gynaecology* in the *Journal* of Oct. 1 (p. 615).

### INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

#### Retirement—Subsequent Receipts

**A. D.** asks whether he is liable for income tax on money earned before but collected after retirement.

**\*\* A. D.** has presumably been assessed in past years on the "cash receipt" basis. If, as is usually the case, such receipts have been year by year a fair index of the gross value of the booking—and assuming that this is true of the last year before retirement—no tax is due in respect of post-retirement receipts.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 25 1947

## PUBLIC HEALTH COMMITTEE

At the last meeting of the Public Health Committee for the new session, held on Oct. 10, Dr. James Fenton was re-elected to the chair. Among the resolutions of the Annual Representative Meeting referred to the committee by the Council was one on safe milk. It was reported that the Ministry of Food had appointed a committee to examine the question of distribution of milk from farm to consumer. The resolution of the A.R.M. was forwarded to the Ministries of Food, Health, and Agriculture. The opinion of the committee was sought by the Secretary of the Association on the recent change whereby, if and when an infant was turned over to artificial feeding, the previous allowance of two pints of milk a week which had been given to the mother was regarded as henceforth belonging to the child, and the mother was left with only the normal adult ration. The view of the committee was that there was a medical case for the continuance of the extra allowance to the mother up to six weeks after confinement in addition to the child's allowance.

It was reported that certain of the associations of local authorities, including the Urban District Councils Association and the Association of Education Committees, had already ratified the agreement arrived at concerning the new revision of the Askwith memorandum, and that other bodies were likely to ratify it shortly.

A question had been raised about the effect of the Education Act on the remuneration of medical officers of health of boroughs and urban districts which as a result of the Act had lost the duties of an education authority, although exercising education functions. In such areas the medical officer whose duties include school medical work continues to have substantially the same responsibility in this respect as he had when the authority was a local education authority before the passing of the Act, yet, strictly speaking, it might be held that his appropriate minimum commencing salary should be on the lower scale set out in the Askwith memorandum. The Advisory Committee concerned with medical officers' salaries, which had been consulted on this point, took the view unanimously that the principle of the usual "non-worsening" or "no detriment" clause should be applied.

### Representation on Local Health Committees

The matter of co-optation of representatives of the medical profession on local health committees arose from a town in the West, where it has been decided to elect a health committee of 30, twenty to be members of the council. Of the ten other members the Division had been requested to nominate one practitioner for co-optation, and the Division felt that one co-opted member would not afford proper representation and that at least three, nominated by a full meeting of the local profession, should serve.

From discussion in the committee it appeared that in this respect the practice of local authorities differed considerably. In one large city the council had refused to have any doctors serving on the health committees unless they were elected members of the council. In a county council the one medical member had not been placed on the health committee.

It was agreed to advise the Division to accept the one seat offered, without prejudice, and to leave it to the Negotiating Committee to raise the general issue with the Minister.

### Other Business

A letter from a divisional secretary drew attention to the fact that in public advertisements advising diphtheria immuni-

zation no mention was made of advice being sought from the patient's own doctor. The advertisements apparently issue from the Central Office of Information, and a possible reason for the absence of any mention of the family doctor is that the posters state that "immunization costs nothing," whereas some local authorities have not yet made arrangements for practitioners to carry out immunization free of charge to their patients. It was agreed to represent to the Ministry of Health that the line hitherto followed by the Central Council for Health Education (whose excellent propaganda work in this field seems to have been taken over by the Central Office, a Government body) is no longer followed.

The committee agreed to support, by a recommendation to Council, the protest of the Medical Women's Federation against the inclusion of an automatic marriage bar in appointments of medical women to public health and hospital posts.

In view of the recent Ministry of Health instruction which ended the power of local authorities to make up civil remuneration of members of their staffs called to the armed Forces, it was agreed to make representations to the Government about the problems which will arise on the calling up for national service of practitioners of older age who are on the staffs of local authorities. An instance was mentioned of a medical officer of health, aged 38, with wife and family, who was shortly being called up.

## HOSPITALS COMMITTEE

A meeting of the Hospitals Committee of the Association was held on Oct. 8. Mr. R. L. Newell was re-elected to the chair for the session; he was also elected to represent the committee on the Public Health Committee. The various matters relating to hospitals which had been the subject of resolutions or references at the Annual Representative Meeting were considered and instructions given for appropriate action. Reports were made of two meetings of the British Hospitals Association and the B.M.A. Liaison Committee, at which the remuneration of visiting staffs of voluntary hospitals had been discussed as well as other matters, such as the Ministry of Health Working Parties.

The committee considered a letter from the Nuffield Provident Guarantee Fund concerning the schedule of surgical operations and special services agreed upon some time ago with the Association. It had been felt on the Association side that the classification required some amendment, and the Fund asked what revision was considered essential and also whether an age limit of 65 would be suitable. It was agreed to set up a joint committee from the Hospitals and the Consultants and Specialists Committee to undertake the detailed examination of the schedules.

### The Elderly Patient

Arising out of the recent report entitled *The Care and Treatment of the Elderly and Infirm*, Dr. W. S. Macdonald suggested that consideration should be given to the importance of liaison between the hospital services and the individual general practitioner concerned with the elderly hospital patient. He said that the whole question of hospital accommodation for the elderly was likely to force itself very quickly upon all sections of the medical profession. Owing to the extreme nursing shortage, it was very desirable to institute some further co-operation between general practitioners on the one hand and hospital staffs on the other in order to get suitable cases into suitable hospitals and also to secure their discharge into proper care when hospital treatment was no longer necessary. This would

be in most cases a less difficult matter to arrange because of the existence of a good district nursing service.

Other members of the committee spoke of the seriousness of the problem of the elderly patient as they experienced it, one member saying that hospitals were "littered" with patients of 65 and over in whose case there was no social or family responsibility to get them out of hospital. Another spoke of a group of 26 elderly female patients, 15 of whom were remaining in hospital simply because there was nowhere else for them to go.

It was considered that this was a matter on which the Regional Hospital Boards and Executive Council must get together. The general practitioner working together with the hospital staff might, as a result of his influence in the homes of the people, help alike the hospitals and the old persons concerned. It was agreed that two members of the committee should write a memorandum formulating positive suggestions which would be considered at the next meeting.

#### Recruitment of Nurses

The committee next considered the report of the Working Party on the recruitment and training of nurses. The chairman said that this was an excellent document and embodied some of the points which the Hospitals Committee had itself recommended. A Scottish member pointed out the unfortunate effect of the migration of young women from Scotland to England or to the Dominions or the U.S.A. In this way about 100,000 had been lost, enhancing the marriageable value of those remaining, and making the position of nursing recruitment in Scotland far more difficult.

A point considered by the committee was the use of male nurses in male wards, but it was realized that if general nursing was thrown open as a profession to men it must offer them a career, and that posts equivalent to those of sister and matron must be attainable. It was the general experience that a number of the men who had come out of the Forces, having had some nursing training, showed great ability in this field. At the same time the view was put forward that the average male patient expected a woman's attendance and that a ward staffed entirely by men might be lacking to some extent in comfort; at all events there was a psychological element in the situation. One member said that his experience was that male patients preferred male orderlies, and another that in an operating theatre staffed entirely by men he had found first-class efficiency. The major difficulty appeared to be residential accommodation.

#### MEDICAL PRACTICE IN NEW ZEALAND

The New Zealand Branch of the British Medical Association is being inundated with letters from medical practitioners in the United Kingdom and India inquiring about the prospects of practising in New Zealand. Indeed, if every practitioner who has inquired this year were to go to New Zealand, writes a correspondent, the number of the profession in general practice would be doubled. Our correspondent points out that the medical profession in New Zealand is already overcrowded. The graduates from the medical school are considerably in excess of annual requirements, salary and income levels are on the whole 40% lower than those of England and India, houses and rooms from which to practise are almost unobtainable, and education for children is not of the type that is generally expected.

A few practices are available for purchase each month, but they are mostly in isolated rural districts, or mining or Maori areas. City or medium town practices cost from £5,000 to £8,000 (including property) and country practices from £2,000 to £6,000; sums as high as £13,000 are being paid. Motor-cars are also expensive and difficult to obtain, waiting lists for new cars imposing a delay of eight to eighteen months. Owing to the small population opportunities for specialist practice are few, and most specialists also engage in general practice. Immigrants who desire to specialize "would encounter extreme difficulty," and it would be unwise for anyone to go to New Zealand anticipating employment in a hospital, for difficulty has already been experienced in placing the country's own ex-Service men.

Our correspondent concludes by saying that those who have £6,000 capital and some private income will be reasonably certain of being able to settle into practice after a period of months but there is little prospect of there being any earnings in the first six months unless arrangements for employment are made before leaving England. Holders of diplomas in public health or psychiatry might obtain posts as tuberculosis officers, district officers of health, school medical officers, or mental hospital officers, at a salary of £700 to £800. A few hospital posts are also available for highly qualified radiologists at a salary of about £1,200. The New Zealand Branch of the B.M.A. is extremely reluctant to advise any practitioner to go to New Zealand at present, and it can do little to assist those who go to the country against advice and then encounter difficulties.

#### HEARD AT HEADQUARTERS

##### Filling up the Ranks

The membership of the Association is steadily approaching 60,000. In September it stood at 57,300, a net gain of 1,700 during the last three months. In those three months the resignations numbered only 43, most of them, of course, due to retirement. Exactly ten years ago, at the time of the Belfast meeting, the membership was bordering upon 37,000, so that in this decade of storm and stress, of war and near-war, of change and criticism, the Association has added 20,000 to its ranks, and this despite the loss of South African members consequent upon the setting up of an affiliated Association for South Africa. The membership is now three times what it was at the beginning of this century. The rate of progress, of course, must slow down as the field of recruitment approaches exhaustion, but we do not now hear people say, as they used to do, "The British Medical Association? But it does not represent the whole profession, does it?"

##### Medical Men on Executive Councils

The Gloucestershire Branch has learned with great pleasure that Dr. J. H. Grove-White, of Cirencester, has been elected to the vice-chairmanship of the county Executive Council. Chairmen of Executive Councils are appointed by the Minister, and in most cases presumably will be laymen, and it was thought in Gloucestershire that it would be to the advantage of the Council itself if the chairman had a member of the medical profession. The medical profession cannot command a majority on Executive Councils, because, of the 24 members appointed by the Local Medical Committee will be doctors. But in view of the work these councils are called upon to do it is obviously desirable that a medical man should fill at any rate the vice-chair, and, apart from personal circumstances which might operate in some localities, the members otherwise appointed might be expected to agree. The usual proviso, of course, remains in force that should negotiations with the Minister break down the appointments will end.

##### Protection of Practices

The London Protection of Practices Scheme came to an end with the end of September. It is one of the last schemes to have closed down. Those concerned are able to look back upon a very honourable and timely piece of work. It is good to know that a comprehensive statement of the work done during the war and after will shortly be published. "Statement," however, suggests a bald record, and this enterprise really deserves to be written up with imagination and sympathy as a first-rate chapter in professional history. It represents a duty well discharged, reflecting particular credit upon those who took part in the work of organization—often a very delicate procedure—and upon the general body of practitioners who accepted the obligations.

##### A Popular Edition

Praise is being given in many quarters to the popular edition of the B.M.A. special committee's report on the care and treatment of the elderly and infirm. Under the title of *When You*

are Old, and illustrated by some most attractive photographs, it tells in popular language the story which the report of the committee had already told in the matter-of-fact language of an official document. Those responsible for its compilation were Dr. E. B. Brooke, medical superintendent of St. Helier Hospital, Carshalton. Dr. Marjory Watren, deputy medical director of West Middlesex Hospital, both of them members of the committee, and Dr. A. Macrae, Assistant Secretary of the Association and the committee's secretary.

### The Marriage Bar

The question of the marriage bar to employment came forward at the last meeting of the Public Health Committee when the Medical Women's Federation asked the Association to join in a protest against the continuance of the marriage bar rule in the Glasgow Corporation and the Northern Ireland Government. The public health authorities in those areas continue to enforce a marriage bar against their medical women employees. Surely the question at issue ought only to be the efficiency of the medical officer. It is true that interruption of service caused by childbirth may arise, but this affects only the earlier years of marriage, and as against any temporary drawback of this kind there is the enrichment which the experience of motherhood ought to give. A recommendation will go from the Public Health Committee to the Council with a view to transmission to the Representative Body that it should reaffirm the view that there should be no automatic marriage bar in the terms of agreement for a medical woman's employment.

### Nurses' Training Schools

The withdrawal by the General Nursing Council of approval from certain nurses' training schools on the ground that the bed capacity or daily bed-occupancy of the hospital falls below an average which the G.N.C. has fixed is causing much difficulty in some quarters. Under the Nurses Registration Act, 1919, any person aggrieved by the refusal of the General Nursing Council may appeal to the Minister of Health, and if the Minister decides in his favour the council is required to comply with the direction given. In the cases so far brought to its attention the Ministry has suggested that action might be taken by the hospitals themselves in the way of amalgamation for training purposes. In the Hospitals Committee the other day it was stated that the Members of Parliament in whose constituency there are hospitals similarly situated are conferring with a view to forming a parliamentary group to approach the Minister and if necessary raise the matter on the adjournment—practically the only opportunity a Member of Parliament now has of bringing forward a matter of public importance.

### Stubborn Geography

The author of *Hudibras* 300 years ago was not forecasting the Regional Hospital Boards when he wrote that "some force whole regions, in despite o' geography, to change their site," but the Regional Boards for Lancashire and for Wales seem likely to have to do a bit of forcing, because administrative arrangements and geographical considerations do not fit. Wales, naturally, desires to retain its administrative integrity in any hospital scheme, but there is the obstinate barrier between North and South Wales, and North Wales has been based on the teaching centre of Liverpool. It is stated that practitioners in North Wales wish to continue the association of that area with Liverpool; on the other hand, specialists resident in North Wales are actively opposed to the continuance of the Liverpool-North Wales alliance. There is, of course, a natural objection to having any such rule as that senior appointments must be made from one particular city, but the circumstances are difficult. The Act states that the Minister shall secure that each regional hospital area is such "that the provision of the said services in the area can conveniently be associated with a university having a school of medicine."

### RELEASE OF MEDICAL OFFICERS FROM THE R.A.F.

The Central Medical War Committee has been informed by the Air Ministry that Royal Air Force Medical Officers in age and service group 64 will be made available for release in December, 1947.

## Correspondence

### Working Hours in the N.H.S.

SIR,—As Dr. W. R. Henderson (*Supplement*, Oct. 4, p. 83) has seen fit to label me as an "elderly fifth-columnist" and a "sanctimonious humbug" for objecting to a State-controlled rota system, may I have a little more of your space to set out my reasons for so doing? If I can help at the same time to lay the boggy of the "24 hours a day, 7 days a week" which seems so to horrify some of your correspondents (I suspect that the more vociferous have never experienced it), so much the better.

I have in my time put in some twelve years in a Government medical service, and for the last fifteen years have run a busy country-town practice, swollen during a good part of the recent war to over 12,000 patients. I hope to continue to do so, provided I am allowed, for a good many years yet. I manage to get a reasonable amount of time off by deputing such work as I cannot or do not wish to do to a brother practitioner without quitting my responsibility to the patient, who recognizes him as my agent.

The crux of the matter lies in calls "out of office hours." These fall into three categories:

(a) *The Trivial*.—My patients recognize that I am a busy man and are usually considerate. If not, they know me well enough to accept a rebuke in good part. If they knew that a doctor were specially detailed to cover the unusual times of day, they would, being only human, try to get their money's worth under the new Act by insisting on being seen at their own convenience, not the doctor's.

(b) *The Borderline Case*.—Knowing as I do the background and history of most of my patients I can often solve or safely defer this type of call over the telephone or by messenger. This could not be done by a rota doctor not equipped with such knowledge.

(c) *The Serious Case (Surgical, Midwifery, etc.)*.—I have a contract, actual or implied, to look after such cases personally or by a deputy I trust, nor would I have it otherwise. From the selfish angle, they include most of what is interesting in my work, and I do not relish sharing them with another not of my choosing.

To put it in a nut-shell, I value the independence of my relations with my patients above whatever inconvenience I may thereby be caused.—I am, etc.,

Beccles, Suffolk.

C. GRANTHAM-HILL.

### Buying and Selling of Practices

SIR,—Dr. S. H. Stewart (Oct. 11, p. 89) wishes to know why the buying and selling of practices takes such a prominent part in the negotiations. His letter is wholly irrelevant to the true point at issue, which is that if the Government is allowed to become the owner of all private practice in England then *ipso facto* the medical service becomes a State service completely, absolutely, and irrevocably. Our independence will have been sacrificed to a soulless machine governed by ex-miners, trade unionists, self-seeking politicians, or even Marxians, according to the political complexion of the Government in power. It is essential that we fight this proposal, however attractive it may appear on the surface, with all the resources at our disposal, if we hope to maintain our traditional status and dignity.—I am, etc.,

Histon, Cambridge.

A. E. MOORE.

### PHARMACY AND POISONS ACT, 1935

Attention is drawn to the Notice published in the *London and Edinburgh Gazettes* dated Oct. 14, 1947, of the Secretary of State's intention to make Rules amending the Poisons Rules, 1935. Any representations in regard to the amending Rules should be made in writing to the Under-Secretary of State, Home Office, St. Stephen's House, Victoria Embankment, London, S.W.1, not later than Nov. 24. A copy of the proposed amending Rules may be obtained from Room 132 at the same address.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

**County Borough Councils.**—Barnsley, Gateshead. (Barrow-in-Furness have now decided that their trade union membership resolution shall not apply to medical officers.)

**Metropolitan Borough Councils.**—Finsbury, Fulham, Hackney, Poplar.

**Non-County Borough Councils.**—Dartford, Leyton, Radecliffe (limited to future appointments), Tottenham, Walsend.

**Urban District Councils.**—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

**Scottish Burghs.**—Motherwell and Wishaw.

## Association Notices

## B.M.A. LIBRARY

The Association's Library is to be transferred from its present accommodation in the main building at B.M.A. House to the first and second floors of the Garden Court wing. To facilitate the removal the Library will be closed from 12.30 p.m. on Saturday, Nov. 1, until 9.30 a.m. on Monday, Nov. 17.

Diary of Central Meetings  
OCTOBER

29. Wed. Council, 10 a.m.

## Branch and Division Meetings to be Held

**BATH, BRISTOL AND SOMERSET BRANCH.**—At Royal United Hospital, Bath, Wednesday, Oct. 29, 8.30 p.m. Annual General Meeting, Presidential address.

**BIRMINGHAM: CENTRAL DIVISION.**—At 154, Great Charles Street, Birmingham, Tuesday, Oct. 28, 8.15 p.m. Clinical meeting conducted by Dr. Ernest Bulmer.

**BOURNEMOUTH DIVISION.**—At Burlington Hotel, Owls Road, Bournemouth, Friday, Nov. 21, at 7.30 p.m. for 7.45 p.m. Annual dinner. Owing to the limitation to less than 100 persons at public dinners, early application for tickets should be made to the honorary secretary, Dr. N. Ross Smith, 9, Poole Road, Bournemouth.

**CLEVELAND DIVISION.**—At Middlesbrough General Hospital, Thursday, Oct. 30, 2.30 p.m. Address by Mr. Bryan Williams: The Conduct of Pregnancy and Present-day Antenatal Work. To be followed by x-ray and cine-film demonstration.

**MID-ESSEX DIVISION.**—At Chelmsford and Essex Hospital, Sunday, Nov. 2, 10 a.m. Dr. Richard Price: Staphylococcal Skin Affections.

Meetings of Branches and Divisions  
EAST AFRICAN BRANCHES

The business meeting was held on the afternoon of Sept. 5 at Mulago Hospital, with Dr. A. J. Boase, President, Uganda Branch, in the chair. An account of other features of the Interterritorial Meeting appears at p. 665 of this issue of the *Journal*. There being agenda on submitted resolutions, a discussion on conditions

Africa was opened by Dr. J. Scott Brown. He said that from his experience with medical officers in Uganda he knew that many were faced with the conditions of service. Briefly, the so-called "grievances" (though he disliked the word) appeared to be: (1) that the average district medical officer was called upon to do so much administrative and clerical work that his professional interests suffered, to the detriment of his patients and of his own professional advancement; (2) that the available hospital facilities were primitive in equipment and staff; (3) that the understaffing of the Colonial Medical Service resulted in a regrettable lowering of the general standard of efficiency; (4) that the salaries were inadequate, particularly the normal maximum of each scale; (5) that, while the status of other Civil Servants had steadily improved during the past 20 years, that of the medical officer had deteriorated, not only relatively but actually; (6) that the abrogation of medico-legal fees and the curtailment of private practice had deprived the medical officer of a reward to which he was morally entitled for extraordinary services; (7) that not only was promotion slow, but there was an unwarrantable delay in filling vacancies in senior posts already provided for in establishment.

Formerly there was compensation for some of these disadvantages in the right to private practice and medico-legal fees. To-day the newcomer was denied these rights. Something would have to be done about it, because in a few years' time, when the men who were joining the Service now would have the problems of a family and its education to face, they would find their salaries inadequate for the purpose. They were, however, fortunate in having some kind of an organization to which most of them belonged—the

B.M.A. For many years the B.M.A. had apparently taken little interest in the affairs of the Colonial Medical Service—judging from results and from the many bitter criticisms of the Association from serving officers. At home, he believed, the Branch Councils consisted of men with more knowledge than the average of how affairs should be conducted, but in the Crown Colonies he doubted if this was so. The Branch Council was usually recruited from hospital clinicians and laboratory workers, whose interest was predominantly concerned with their work. The important office of secretary tended to be wished on to some junior new arrival. On the whole these officers had a congenial occupation, amenities, and consulting practice, and were reasonably contented with their lot, for which reasons they were not likely to start and sustain any campaign for the relief of "grievances" in the Service generally.

As regards H.Q. in London, he could only give sketchy impressions gained through representing the Uganda Branch on two occasions at the A.R.M., from both of which he came away with the feeling that any mention of grievances or dissatisfaction by a Colonial Servant was liable to be brushed aside as a trifling nuisance. His opinion had been that B.M.A. H.Q. had been defeatist in their attitude to the Colonial Office and that they had not been deeply concerned with anything outside the U.K., certainly not in the Crown Colonies. He did not think that the B.M.A. had no other function than to redress the grievances of its members, but none of its functions could operate properly unless its machinery was in good order. The aims, objects, and ideals of the B.M.A. were sound, but he believed that its machinery as it functioned in relation to Crown Colonies was definitely in need of an overhaul.

So far he had criticized the B.M.A., but some thought must be given to the authorities with which the B.M.A. had to deal. Gathering together these rather disconnected ideas, he was forced to the opinion that doctors in the Colonial Medical Service had need now of protection and that their only hope lay in the B.M.A. Further they would have to help themselves. If the machinery was wrong let them put it right. He proposed that an endeavour be made to develop a close liaison between the different Branches in each group of the Crown Colonies. It should be possible, and it would certainly be helpful, for every Branch in East Africa to send copies of their minutes to every other Branch and in the same way to exchange copies of all correspondence to and from H.Q. in London. If this were done, matters of common interest would soon become apparent, and they could iron out differences and develop their ease. Giving the Crown Colonies a section of their own with appropriate and active representation at the "highest level" a H.Q. was a good move. "Do not let us delay unduly in assessing what grievances we have, if any, and in deciding what to do about them, if anything, remembering that in unity lies strength."

On behalf of the Council of the Uganda Branch, Dr. Davie proposed the following resolutions:

(1, seconded by Dr. McKenzie, Tanganyika) That closer co-ordination between the East African Branches of the Association is essential and that the Branches should take steps in this matter and should seek assistance from the parent body.

(2, seconded by Dr. Scott Brown) That this meeting requests the Council of the parent body to send to East Africa from time to time a secretary to assist the Branches, and particularly to assist the Branches in the discussions which will be needed consequent upon the report of the East African Salaries Commission.

(3, seconded by Dr. Carman) That this meeting fully endorse the view of Council as stated in Minute 134 of the Council's Report to the Annual Representative Meeting 1946-7.

(4, seconded by Dr. Raper, Uganda) That this meeting state that the salaries paid to members of the Colonial Medical Service should be based upon the Spens Report plus an expatriation allowance.

All were carried *nem. con.*

## H.M. Forces Appointments

## COLONIAL MEDICAL SERVICE

The following appointments have been announced: E. G. I Butler, M.B., B.Ch., Medical Officer, Tanganyika; S. C. Ferguson, M.B., B.Ch., Medical Officer, Nigeria; A. B. G. Laing, M.B., L.R.C.P.S.I., Medical Officer, Malaya; T. L. McCullagh, M.B., B.S. Ch.B., Medical Officer, Malaya; J. R. Murley, M.R.C.S., L.R.C.P., Medical Officer, Aden; A. Etmayer, M.B., Ch.B., Medical Officer, British Somaliland; N. A. St. C. Marley, L.M.S.S.A. Officer, Windward Islands; J. P. Murray, M.B., B.Ch., and H. I. Medical Officer, Jamaica; J. P. Murray, M.B., B.Ch., and H. I. Medical Officer, House Doctors, King Edward VII Hospital, Malaya; H. B. Taylor, M.B., Ch.B., District Medical Officer, Bahamas; T. Thornton, F.R.C.S., Surgeon, Specialist, Palestine; J. E. O'N. Gillespie, M.D., Specialist (Physician), Cyprus; A. Howell, M.R.C.S., L.R.C.P., Deputy Director of Medical Service, Northern Rhodesia; J. H. Pottinger, M.B., Ch.B., Senior Medical Officer, Nigeria.

**Correction.**—Referring to a dispute between the North of England Branch of the Association and the officers of the National Union of Mineworkers, we reported in the *Supplement* of Oct. 18 (p. 9) that the Branch had sought an increase in the payments under its scheme by 1s. 6d. a fortnight for each family for medical attendance. This should have read "an increase to 1s. 6d. a fortnight."

# BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 1 1947

## ALL THE VITAMINS

BY

LESLIE J. HARRIS, Sc.D., D.Sc., F.R.I.C.

*Dunn Nutritional Laboratory, University of Cambridge, and Medical Research Council*

**Q.**—Please give a list of vitamins with all their different names and with notes on the signs and symptoms of deficiency.

**A.**—The answer would take more space than can be allowed in "Any Questions?" and at the request of the Editor the following article has been contributed.

The vitamins which so far have been shown to be needed by man, or to be of undoubted clinical significance, are the following: vitamin A; vitamin B<sub>1</sub>, three components of the vitamin B<sub>2</sub> complex—namely, nicotinic acid, riboflavin, and folic acid—vitamins C, D, and K, together with several different forms and modifications of most of them.

The significance of some other vitamins for human nutrition is still somewhat uncertain: these include two additional "B<sub>2</sub> vitamins" (biotin—vitamin H—and choline), and also vitamins E, F, and P.

A third group of vitamins comprises those which have so far been demonstrated only by means of animal experiments. These consist of four vitamins of the B<sub>2</sub> group (vitamin B<sub>6</sub>—pyridoxin—pantothenic acid, inositol, *p*-aminobenzoic acid). The vitamins will be described in three groups in the above order.

### I. Vitamins Needed by Man

#### Vitamin A

These include vitamin A proper (otherwise called vitamin A<sub>1</sub> or xerophthol) and the principal provitamin,  $\beta$ -carotene. There are several other forms of vitamin A—namely, vitamin A<sub>2</sub>, anhydro-vitamin A, subvitamin A—and several other active carotenoids also serve as provitamins in addition to  $\beta$ -carotene—for example,  $\alpha$ - and  $\gamma$ -carotene, kryptoxanthine, leprotene, echinenone, myxoxanthine, aphanene, aphanicene—but none of these have any special medical interest. The signs and symptoms of deficiency of vitamin A may include: diminished powers of dark adaptation (this is the earliest and most delicate diagnostic sign), progressing to night blindness; xerosis and keratinization of various membrane tissues, giving rise to a liability to local infections; a keratinized follicular papular eruption in the skin; xerotic changes in the conjunctiva and cornea (best detected by slit-lamp inspection or examination of corneal scrapings for keratinized cells), leading to "Bitot's spots" and to xerophthalmia and, in advanced cases, keratomalacia. In experimental animals other changes observed in deficiency include renal calculi, degenerative changes in the central nervous system, periodontal hyperplasia, overgrowth of bone, failure in reproduction, and of course impaired growth rate. (Among

the first signs of inadequate intake, of this or any other vitamin, is poor growth.) The best sources of vitamin A include halibut-liver and cod-liver oils, mammalian liver, and milk (or fortified margarine); as carotene it occurs abundantly in green leafy vegetables and in carrots; eggs and butter contain both carotene and vitamin A. The League of Nations standard of requirement is 3,000 i.u. (1 i.u.=0.6 microgram of  $\beta$ -carotene), but carotene is only about one-half or one-third as well utilized by the animal body compared with an equal amount of vitamin A.

#### B Group of Vitamins

This comprises the heat-labile vitamin B<sub>1</sub>, and the heat-stable vitamin B<sub>2</sub> complex of vitamins (see below).

*Vitamin B<sub>1</sub>* (aneurin hydrochloride or thiamin hydrochloride) occurs also in nature as the pyrophosphate ester or co-carboxylase. This is the anti-beriberi or antipolyneuritic vitamin. Beriberi, common in the East among populations subsisting too exclusively on diets of "polished" (white) rice, is characterized by polyneuritis of the peripheral nerves (typical manifestations being the patches of paraesthesia in the lower limbs, diminished knee-jerks, wrist-drop, high-stepping gait), by cardiac irregularities (shortness of breath, dyspnoea, tachycardia, dilatation of the right side of the heart), muscular weakness, anorexia, and sometimes emaciation ("dry beriberi") or oedema ("wet beriberi"). The disease may follow several different forms depending on whether the polyneuritic, cardiac, or oedematous symptoms predominate.

Conditioned deficiency of vitamin B<sub>1</sub> (secondary polyneuritis), as distinct from the endemic deficiency seen in the Orient, occurs from time to time in Western countries—as in polyneuritis arising from gastro-intestinal obstruction (which causes faulty absorption of the vitamin), in alcoholic polyneuritis, and in the polyneuritis of pregnancy. In infants and children suboptimal intake of vitamin B<sub>1</sub> has been thought to lead to inadequate growth and gastro-intestinal hypotonia.

The national wheatmeal loaf (about 80–85% extraction) has been an important source of vitamin B<sub>1</sub> in Great Britain since the beginning of the second world war, white flour (72% extraction) containing negligible amounts. The best foods for vitamin B<sub>1</sub> include: dried brewers' yeast (c. 1,000–2,000 i.u. per 100 g.), wheat germ, rice germ, barley germ (c. 1,000), oatmeal (c. 300), wholemeal wheat flour, peas, haricot beans, egg yolk (c. 100). The League of Nations standard of requirement for vitamin B<sub>1</sub> is 300 i.u. per day (1 i.u.=3  $\mu$ g.=0.000,003 g.).

*Vitamin B<sub>2</sub>* when first recognized was thought to be a single factor, and defined as the "heat-stable, water-soluble fraction present in extracts of yeast which prevents pellagra in man, black-tongue in dogs, and a so-called pellagra-like dermatitis in rats and is needed also for promotion of health and growth in rats." As so defined, vitamin B<sub>2</sub> is in reality a complex of at least nine vitamins (including nicotinamide, riboflavin, pyridoxin, pantothenic acid, p-aminobenzoic acid, inositol, choline, biotin, and folic acid). The term is sometimes used, but less accurately, as synonymous with riboflavin.

### B<sub>2</sub> Vitamins Needed By Man

(a) *Nicotinamide* (otherwise called nicotinic amide, or niacin amide, or "P-P," or pellagra-preventing, vitamin). The parent substance, nicotinic acid (or niacin), is likewise active, being doubtless converted to the amide in the animal body. In the combined form, in living tissues, nicotinamide occurs as a component of certain enzyme systems—namely, as the two "pyridine coenzymes" (1) codehydrogenase I, or "Euler's cozymase," diphosphopyridine nucleotide, and (2) codehydrogenase II, or "Warburg's enzyme," triphosphopyridine nucleotide.

The signs and symptoms of pellagra in man may be summarized under four headings: (1) The characteristic glossitis and stomatitis, including the "beefy tongue." (2) There develops a persistent diarrhoea. (3) Most typical are the skin lesions. These begin as an erythema resembling sunburn, and progress into a deeper dermatitis, followed by a pigmentation and a great thickening of the dermis. The pathognomonic feature of these eruptions is that they are bilaterally symmetrical, possess a well-defined pigmented border, and occur especially on the parts of the body exposed to the sun or to friction, including the back of the hands and wrists, the face, the upper part of the chest, and the perineal region. (4) Mental symptoms develop as the disease progresses, and in the absence of treatment insanity results.

"Secondary pellagra," or "conditioned deficiency" of nicotinamide, with symptoms similar to the above, is caused by faulty absorption or assimilation of the vitamin, as, for example, in the pellagra of chronic alcoholism or in gastro-intestinal obstruction.

The daily requirement of nicotinamide (preventive) is probably about 10–12 mg. The best sources in food include yeast and liver (or yeast and liver extracts), fish (e.g., canned salmon), meat, pulses, whole wheatmeal or bran, but there is practically none in white flour.

(b) *Riboflavin* was formerly called lactoflavin (or oboflavin, or hepatoflavin, etc., according to its origin) and is still sometimes known as B<sub>2</sub>. (More strictly speaking, this term was correctly used when riboflavin was the only known "B<sub>2</sub>" vitamin, before it was found to be a complex.) In living tissues riboflavin occurs in the combined form as a coenzyme—namely, iso-alloxazine-adenine-dinucleotide, a component of the enzyme systems known as flavoproteins.

Riboflavin deficiency in man causes a typical "cheilosis" (lesions of the lips) and an angular stomatitis characterized by cracks, scaliness, and maceration at the corners of the mouth, developing into a deep fissuring. Corneal changes, opacity, and vascularization have also been described; but probably both oral and ocular symptoms lack full specificity. In experimental animals the deficiency is likewise marked by corneal lesions and dermatitis, as well as by growth failure. In addition, in birds, deficiency results in a condition described as "curled toe," and is of much practical importance in poultry husbandry. In dogs a condition described as "yellow liver" has been produced.

The daily requirement (preventive) is probably about 1–2 mg. Foods rich in riboflavin include yeast, liver, kidney, milk, and egg-white.

(c) *Folic acid* is probably identical with or closely related to factors known severally as the grass juice factor (for guinea-pigs), vitamin B<sub>9</sub> (anti-anaemia factor for chicks), vitamin M (for monkeys), and the growth factors for the micro-organism *Lactobacillus casei* and for *Streptococcus lactis* R. In chemical structure it is built from glutamic acid p-aminobenzoic acid, and pterin residues; and certain other pterin derivatives may also be active. Folic acid has been shown to produce a haematopoietic response in Addisonian pernicious anaemia and in some other macrocytic anaemia in man; it is, however, apparently ineffective in controlling cord degeneration in pernicious anaemia. Remarkably success is said to have followed its use in treatment of sprue. A possible anticarcinogenic action is being examined experimentally in animals.

### Vitamin C

Vitamin C, or *L*-ascorbic acid (formerly known also in the U.S.A. as cevitamic acid), is the anti-scurvy (antiscorbutic) vitamin. The closely related, and somewhat unstable reversibly oxidized derivative, dehydroascorbic acid, is also active, and several artificially prepared chemical analogues show some varying degree of activity. Characteristic symptoms of scurvy in the adult are the haemorrhagic manifestations, particularly the spongy gums and the petechiae in the trunk or limbs. Among the early signs may be a follicular hyperkeratosis. In advanced cases there is a pronounced secondary anaemia. Bronchitis and other infections often occur as a complication. The associated symptoms may include sallowness, lassitude and mental depression, pains in the lower limbs, and hardening of the calf muscle due to haemorrhage. In infantile scurvy the diagnostic features include: (1) a tenderness in the lower limb as a result of which the child adopts a characteristic attitude, dreading to be touched; (2) subperiosteal haemorrhage with swelling, e.g., near the lower end of the femur; and (3) the radiological appearance of the long bones, showing a cessation of osteogenesis; the oral lesion may be absent. In scurvy there is an extreme degree of depletion of ascorbic acid from the tissues, as shown by the number of test doses needed before an overflow of the excess into the urine, where it can be estimated by chemical test.

The League of Nations standard requirement is 30 mg per day. The best sources of the vitamin include, among fresh fruits (in decreasing order): blackcurrants, straw berries, oranges, lemons, grapefruit, gooseberries; there is relatively little in pears, plums, grapes, or some varieties of apples. The richest vegetables include (also in decreasing order): Brussels sprouts, cauliflower, cabbage, and new potatoes. During the cooking of vegetables the loss of vitamin C can be minimized by avoidance of such conditions as the use of excessive amounts of cooking water, an undue prolongation of the time of heating, too much shredding of the vegetable before cooking, and overmuch keeping hot or re-cooking before serving.

### Vitamin D

Vitamin D is the antirachitic vitamin. The two most important forms are: (1) vitamin D<sub>2</sub>, or calciferol, prepared artificially by ultra-violet irradiation of ergosterol and present also in certain irradiated plant materials; and (2) vitamin D<sub>3</sub>, or irradiated 7-dehydrocholesterol (cholestadien-3-ol), present naturally in fish-liver oils, including halibut, tunny, and cod. Other D vitamins, of little more than academic interest, are the following: irradiated heated

cholesterol; cholesterilene sulphonic acid; irradiated 22-dihydroergosterol; irradiated 7-dehydrositosterol. Rickets (vitamin D deficiency) is characterized particularly by deficient calcification of the bones, especially in the newly forming bone at the epiphysis, where the zone of provisional calcification is increased in breadth and inadequately mineralized. The consequent irregular growth of soft tissue causes the typical swellings at the epiphyseal junctions ("rachitic metaphysis"). The bending of the adequately calcified bones and the overgrowth of osteoid tissue in turn give rise to the well-recognized deformities—bow-legs, knock-knees, rachitic pelvis, "green-stick" fractures, the enlargement of the ends of the bones, and the bending of the ribs. Active rickets is characterized by a deficiency level of inorganic phosphate in the blood and sometimes of calcium, causing spasmodophilia (tetany), and an increase in blood phosphatase. The fundamental chemical lesion in vitamin D deficiency is excessive loss of phosphate and/or calcium in the faeces, with a concurrent drop in their levels in the blood and consequent inadequate calcification of bony tissues. Severe rickets is of course readily detected by the clinical signs, but mild cases of rickets may need x-ray diagnosis.

Legitimate "pharmacological" uses of vitamin D—i.e., in the absence of rachitic signs—are: (1) to maintain the level of the blood calcium after parathyroidectomy, and (2) in the treatment of lupus vulgaris by massive local injection. Vitamin D occurs in fish-liver oil (halibut, cod, tunny, etc.) and in smaller quantity in egg yolk and in vitaminized margarine and butter. The international unit is 0.02  $\mu$ g. of calciferol, the protective dose in early childhood about 500 to 1,500 i.u. per day, and an effective curative dose 1,500 to 3,000 i.u. per day: larger doses may be toxic. For nursing and expectant mothers 1,000–2,000 i.u. daily may be prescribed in order to improve the assimilation of calcium and phosphate and to make good the losses of these elements by the foetus and in the milk.

#### Vitamin K

Vitamin K includes vitamin K<sub>1</sub> (2-methyl-3-phytyl-1,4-naphthoquinone) and vitamin K<sub>2</sub> (2-methyl-3-difarnesyl-1,4-naphthoquinone). Active homologues include various other methyl-1,4-naphthoquinone derivatives—for example, thiocol (2-methyl-3-hydroxy-1,4-naphthoquinone) and the parent substance itself, 2-methyl-1,4-naphthoquinone. The last-mentioned, because of its solubility and ease of absorption, is the form of vitamin K most favoured in medicine. In experimental chicks and other species, deficiency of vitamin K causes a lowering of the prothrombin value of the blood, and this results in a haemorrhagic syndrome. In clinical practice vitamin K has been of great service in controlling those haemorrhagic conditions that are due specifically to hypoprothrombinaemia—namely, (a) in haemorrhagic disease in the newborn, associated with a transient hypoprothrombinaemia; (b) after surgical treatment of obstructive jaundice; and (c) in the hypoprothrombinaemia associated with steatorrhea, sprue, and intestinal obstruction. It is believed that (a) the transient hypoprothrombinaemia can be attributed to the fact that symbiotic microflora, which normally synthesize vitamin K, have not yet become established in the intestine of the infant through the ingestion of food; (b) and (c) a faulty absorption of vitamin K is considered to be responsible for the deficiency. In treatment, 1 to 4 mg. of 2-methyl-1,4-naphthoquinone daily is commonly used, given either by injection or by mouth. In the prophylaxis of hypoprothrombinaemia in the newborn the vitamin may be administered as a prenatal routine to the mother, or to the child at birth.

## II. Vitamins of Probable or Possible Significance for Humans

**Biotin**, a growth factor for yeast and other micro-organisms, is identical with the so-called vitamin H (= *Haut* [skin] *Faktor*, or anti-eggwhite injury factor for rats and other animals) and with coenzyme R (growth factor for micro-organisms in the nodule of legumes). It protects rats and other experimental animals from seborrhoeic skin lesions and other abnormalities when they are fed on a special diet containing raw egg-white as an ingredient. The latter contains a protein-like substance or antivitamin, "avidin," which inactivates the vitamin and is destroyed by cooking. Clinical relations are still obscure, although biotin deficiency has been produced experimentally in the human subject by means of a diet of raw egg-white, and there is at least one record of a primary deficiency having been described.

**Choline** functions in chemical physiology as a trans-methylating agent, and as such is replaceable by the amino-acid methionine, or by betaine. In experimental animals choline deficiency results in a fault in fat transport and consequently in fatty liver (sometimes accompanied by necrosis), as well as by haemorrhages in the kidney, paralysis, and other ill effects. Possible clinical applications still remain to be defined, although its use has been proposed to control a negative-nitrogen balance in conditions similar to those in which methionine or a high-protein diet has been found effective.

**Vitamin E** includes  $\alpha$ -tocopherol (5,7,8-trimethyl-tocol),  $\beta$ -tocopherol (5,8-dimethyl-tocol),  $\gamma$ -tocopherol (7,8-dimethyl-tocol), and several related synthetic derivatives. In rats or other experimental animals deficiency of vitamin E causes: (1) reproductive failure, due in the female to resorption of the foetuses during gestation, and in the male to degeneration of the germ cell; (2) muscular dystrophy; (3) degeneration of muscle fibres, leading to discoloration of the uterus and other tissues; (4) degeneration of the epithelium of the convoluted tubules of the kidney; (5) an "exudative diathesis"; and (6) dental depigmentation. Many claims have been made for the successful use of vitamin E in treatment of habitual abortion in women, but adequately controlled experiments still seem to be lacking. The supposed effectiveness of vitamin E in treatment of muscular dystrophies lacks confirmation. The richest sources of vitamin E include wheat-germ and rice-germ oils, cotton-seed oil, and green leaves. In contrast with vitamins A and D it is absent from cod-liver oil and other fish-liver oils.

"**Vitamin F**" is a synonym for the nutritionally essential unsaturated fatty acids—namely, linoleic acid, linolenic acid, and arachidonic acid. Symptoms of deficiency in rats include a scaliness of the tail sometimes leading to caudal necrosis, irregularities in reproduction, and kidney lesions. Deficiency of "vitamin F" has not been recognized to occur in the human, but claims have been made for its use in eczematous conditions.

**Vitamin P**, a group of substances including citrin (hesperidin glucoside), is claimed to be concerned in controlling fragility of capillary blood vessels, and to be needed as an adjunct to vitamin C in the cure of some symptoms associated with scurvy: this, however, is disputed.

## III. Vitamins Needed by Experimental Animals: Significance for Humans Uncertain

**Pyridoxin** (adermin, vitamin B<sub>6</sub>) prevents a deficiency disease in rats characterized by a florid symmetrical dermatitis of the extremities. Another sign in rats, as also in pigs, may be the occurrence of fits. Pyridoxin is thought

to be concerned in the synthesis of fats from protein, and perhaps in tryptophan metabolism. Biologically active derivatives also include pyridoxal (concerned in tyrosine decarboxylation and possibly in biochemical transaminations) and pyridoxamine. Another derivative, pyridoxic acid, is described as a dietary factor for chicks. The need of man for pyridoxin has been questioned: symptoms of deficiency are, however, said to include cheilosis resembling that seen in deficiency of riboflavin. Pyridoxin has recently been used in the treatment of agranulocytosis.

**Pantothenic acid** (formerly called "chicken pellagra factor" or "filtrate factor") prevents a characteristic dermatitis in birds. It is needed also by dogs and pigs. Signs of deficiency in rats include growth failure, dermatitis, nose-bleeding, depilation about the nose, occurrence of a sticky exudate in the eyelids, and achromotrichia, together with adrenal lesions. It is also a growth factor for micro-organisms. Pantothenic acid is thought to be probably needed by humans, but its significance is still obscure.

**Inositol** is identical with bios I, needed for growth of yeast and other micro-organisms. An experimental deficiency in rats or mice is said to cause alopecia. Deficiency in man is unknown, but inositol may possibly be a "secondary nutrient"—that is, it may stimulate the intestinal microflora to synthesize other nutrients essential to the host.

**Para-aminobenzoic acid** (or "Paba") is a growth factor for various micro-organisms, and is said to prevent achromotrichia in some experimental species. It may be a "secondary nutrient" (see above) for man. Its special interest is that drugs of the sulphonamide type exert their bacteriostatic action by "blocking" the bacterium's supply of Paba. Conversely, Paba can negate the bacteriostatic action of the sulpha-drugs. Recent work suggests that large doses of Paba itself may exert an anti-infective action in animals in some circumstances.

## "Q" FEVER

### A SEROLOGICAL INVESTIGATION OF A GROUP OF CASES PREVIOUSLY REPORTED AS PRIMARY ATYPICAL PNEUMONIA

BY

J. E. CAUGHEY, M.D., M.R.C.P., F.R.A.C.P.

Physician to the Auckland Hospital, New Zealand

AND

J. A. DUDGEON, M.C., M.D.\*

Derrick (1937) first described "Q" fever in Australia, and the causative agent was isolated by injection of the blood and urine into guinea-pigs. Burnet and Freeman (1937) showed that the infective agent was a rickettsia, which was subsequently named *Rickettsia burneti*. In the winter of 1944 an epidemic of so-called primary atypical pneumonia occurred among New Zealand troops in the Cassino area (Adams and Porteous, personal communication).

Later in 1944 Turner (1945) recorded a similar epidemic of 280 cases from the Naples area. During the same year an outbreak of primary atypical pneumonia occurred among German troops in Greece, and was referred to by them as "Balkan grippé." Dr. Caminopetros, at the Pasteur Institute in Greece, was able to establish the infection in guinea-pigs by injection of blood taken from cases in the early stages of the infection. Subsequently, blood taken from these guinea-pigs was investigated at the laboratories of the Commission on Acute Respiratory Diseases at Fort

Bragg, North Carolina (1946), and *R. burneti* was isolated. In the winter of 1945 an epidemic of "atypical pneumonia" occurred among New Zealand and British troops in the Naples and Caserta area. Similar epidemics arose among British and American troops in the Mediterranean theatre of operations. Detailed studies of some of these epidemics have recently been reported by Robbins and Rustig (1946). In a British parachute regiment, probably infected in Athens before being transferred to Italy, serological tests later established the diagnosis of "Q" fever. Four epidemics among U.S. troops in Northern Italy were fully investigated. *R. burneti* was isolated from the blood in some of these cases, and by serological tests it was demonstrated that 75% of the cases of "atypical pneumonia" in the same area were in fact cases of "Q" fever.

In May, 1945, an epidemic of "atypical pneumonia" occurred in mid-Atlantic amongst a group of airmen who had recently been stationed at Grottaglie Air Base, Southern Italy, in the Taranto area. These were fully investigated when the airmen arrived at Camp Patrick Henry, Virginia (Feinstein *et al.*, 1946). Epidemiological and aetiological studies were made, and it was demonstrated that the infective agent was the "Balkan grippé" strain of *R. burneti* (Commission on Acute Respiratory Diseases, 1946).

Clinically the epidemic of so-called primary atypical pneumonia recorded by Adams *et al.* (1946) was very similar to the cases recorded by Robbins and Rustig (1946) and by Feinstein *et al.* (1946), in which the aetiological agent was established as *R. burneti*. On this account it was decided to attempt to establish the infective agent in the New Zealand Hospital cases.

### Clinical Features

For complete clinical details of the cases readers are referred to the original report of Adams *et al.* (1946). The main clinical features may be summarized for the sake of completeness.

The epidemic occurred between February and April 1945, and during this period 511 cases were reported in the Naples-Caserta area, 161 of which were treated at the N.Z. General Hospital. Of these, 50 consecutive cases were studied in detail clinically and by serial pathological and radiological investigations.

In brief, the clinical picture was as follows. In most cases there was a prodromal period of about six days. The actual onset was abrupt in 96%, and severe headache, malaise, lassitude, and anorexia were the most constant symptoms. Pyrexia from the onset averaged 8.6 days, over 103° F. (39.4° C.) in 70% of cases, and defervescence was by lysis in 86%. The pulse followed the temperature though it showed a tendency to a relative bradycardia. The respiratory rate was little affected. Cough was present in 94%, but was not an outstanding feature; it occurred about the fifth day. Sputum was scanty and in 28% contained blood. Chest pains occurred in 46% of the cases, and 26% of these a pleural rub was detected.

**Physical Signs.**—Severe toxæmia was a feature of some cases, and one-third showed generalized rhonchi on admission, but the most characteristic sign was a localized patch of sticky persistent crepitations, which were heard on average on the sixth day from the onset of the acute symptoms. Usually there was enlargement of glands, the spleen was palpable in 36% of cases. Scanty salmon pink macules fading on pressure were observed on the chest back, and flanks in the early stages in 34% of cases.

**Laboratory Investigations.**—The results of serial pathological investigations can be summarized in brief. The white cell count revealed a slight polymorphonuclear

\*A member of the scientific staff of the National Institute for Medical Research, Hamstead, London, at the time of this investigation.

response followed by a slight depression, which was maximal at the end of the first week. Thereafter there was a rise of polymorphs and lymphocytes, reaching a peak at the 5th to 18th day. Differential counts showed a slight relative lymphocytosis after the initial period. The blood sedimentation rate was elevated for two to three weeks. Cephalin-cholesterol flocculation was insignificant early in the disease but increased rapidly after convalescence had been established in the second week, thereafter falling slowly. Using horse cells, a significant positive heterophil antibody reaction was found in 36% of the cases at some stage of the disease. All but three, which were weakly positive, gave negative tests for cold agglutinins at all stages.

**Radiological Investigations.**—Postero-anterior and lateral studies were made in all cases. The characteristic findings were the localization of the lesion to one or more bronchopulmonary segments. The infiltration could be described as hazy mottled densities. These investigations also revealed the importance of the lateral studies for the demonstration of lesions situated beyond the heart shadow or in that portion of the lung situated behind the summit of the dome of the diaphragm. Complete radiological resolution in the majority occurred within six weeks of the onset.

### Epidemiology

The possible route and sources of infection were examined in detail in some of the Northern Italian epidemics, and although no vectors such as ticks or fleas were incriminated it was found that the disease often made its appearance in units occupying farm billets and also where men were living in close proximity to animals such as cattle, cats, and pigeons. Various forms of insects were discovered in several of these billets, but it was thought that cases probably occurred by inhalation infection arising from the dust and droppings. The complete absence of insect-bites in any of the cases and the uniform picture of pulmonary involvement suggested that the route of infection was via the upper respiratory tract, such as probably occurred in the laboratory infection with the same agent (Robbins and Rustigian, 1946) and as is also seen in laboratory infections with other rickettsial diseases such as epidemic, murine, and scrub typhus. It was also found that many of the civilian population in the area where these cases occurred showed a high level of antibody to "Q" fever, which suggests that the infection was endemic in the local inhabitants.

In the New Zealand Hospital cases most of the patients came from a British infantry training depot where men were living in hutments and in which there was a rapid turnover of personnel. The staff of the hospital escaped lightly. A strict isolation technique was carried out in the wards until the temperature had been normal for a week or until productive cough had ceased. The regimental aid-post orderly, who treated men daily from the infantry training depot, and the hospital librarian, who visited the wards, both contracted the disease, but no case to our knowledge occurred among the nurses and orderlies who were attending the patients.

### Serological Investigation

Of the 50 cases recorded by Adams *et al.* (1946), 47 were in United Kingdom troops; the remaining three occurred in New Zealand troops. As a test case, serum was taken from one of the latter and a glycerinated specimen was forwarded by air from New Zealand in 1946 to Dr. Norman Topping, Assistant Director of Health of the Division of Infectious Diseases of the National Institute of Health at Bethesda, Maryland. It was tested for complement fixation against antigen prepared from a strain of *R. burneti*

isolated in Italy. The serum was slightly anticomplementary, but in Dr. Topping's opinion the anticomplementary activity had no real significance when compared with the titres against the antigen (Table I).

TABLE I.—Complement-fixation Titre with Italian "Q" Fever Strain

	1 : 8	1 : 16	1 : 32	1 : 64	1 : 128	1 : 256
N.Z. test serum	4	4	4	4	3	Trace
Control serum	4	1	0	0	0	0

Subsequently one of us, with the assistance of the staff of A.M.D. 7 of the War Office, was able to collect sera from 21 of the 47 British cases. These were forwarded to Dr. Topping. Nineteen of them arrived safely and on test gave a positive complement-fixation reaction to the Italian strain of "Q" fever (Table II). It will be seen that in some the titres are low, but it has to be remembered that the initial infection occurred almost two years before the date of testing the sera.

TABLE II.—Result of Complement-fixation Test for "Q" Fever (Italian Strain)

No. of Serum	Titre	Result	No. of Serum	Titre	Result
1	1 : 64	+	13	1 : 32	+
2	1 : 32	+	14	1 : 32	+
5	1 : 32	+	15	1 : 64	+
6	1 : 16	+	16	1 : 4	+
7	1 : 8	+	17	1 : 32	+
8	1 : 4	+	18	1 : 16	+
9	1 : 64	+	19	1 : 32	+
10	1 : 16	+	20	1 : 32	+
11	1 : 8	+	21	0	-
12	1 : 16	+	22*	1 : 128	+

\* Serum sent from New Zealand.

Professor S. P. Bedson kindly tested these sera for antibody to the virus of psittacosis. They were all uniformly negative.

Hence, out of 20 cases checked, 19 gave a positive complement-fixation reaction to the Italian strain of "Q" fever, and it is reasonable to assume that the infective agent of these cases of "primary atypical pneumonia" was the Italian strain of *R. burneti*.

### Summary

An epidemic of "primary atypical pneumonia," previously recorded in the *British Medical Journal* as having occurred in the Naples-Caserta area in 1945, has been further investigated serologically, and 19 out of 20 sera tested gave a positive complement-fixation reaction to an Italian strain of "Q" fever two years after the initial infection. It is probable that the epidemic of so-called primary atypical pneumonia was in fact "Q" fever caused by an Italian strain of *R. burneti*.

We wish to thank Professor F. M. Burnet, Director of the Walter and Eliza Hall Institute, Melbourne, and Dr. C. H. Andrewes, of the National Institute for Medical Research, London, who gave valuable advice in this investigation. We also wish to thank Dr. R. E. Dyer and Dr. N. H. Topping, of the National Institute of Health, Bethesda, Maryland, U.S.A., for carrying out the serological tests on these patients; also Brigadier J. S. K. Boyd, lately Director of Pathology at the War Office, and Lieutenant-Colonel P. Sayers, R.A.M.C., of the War Office, who arranged to trace these soldiers after demobilization. In addition we wish to thank the many pathologists, too numerous to mention individually, who kindly helped to collect the serum from these cases. Finally, we have to thank Dr. W. E. Henley, with whom one of us has constantly consulted.

# THE PLASMA VISCOSITY IN RHEUMATIC DISEASES

BY

I. C. COWAN, B.Sc., M.B.

Physician in charge of Physiotherapy Department

AND

JOHN HARKNESS, B.Sc., M.B.

Biochemist

(From the Arthritis Clinic of Sunderland Royal Infirmary)

In 1942 on a series of 63 tuberculous patients Miller and Whittington (1942) introduced the estimation of the plasma viscosity as a clinical test. They showed that there was a close correlation between the clinical condition and the viscosity value.

In the course of some 650 determinations which included non-tuberculous conditions the usefulness of the viscosity test was confirmed (Houston *et al.*, 1945; Harkness *et al.*, 1946). These experiments also demonstrated the complex "periodic" relationship between the plasma viscosity and the maximum erythrocyte sedimentation rate (Whittington, 1942), showing that if the viscosity is a reliable quantitative index of the clinical state then the E.S.R. is not. The conclusion drawn from that series of experiments was that the viscosity is to be preferred to the E.S.R. as an index.

While the only rheumatic condition in the series was a single case of rheumatic fever, Whittington (1946) suggested the application of the test in rheumatic diseases generally. It has recently been possible for us to apply the test in a series of patients suffering from all types of rheumatic conditions. In doing this we had as our objective the evaluation of the plasma viscosity test as an aid to the clinician in the handling of these rheumatic conditions. At this stage it may be said that the test has proved to be so useful that it is now included in the routine assessment of new patients and in following the progress of others in response to treatment.

The establishment of new treatment centres and research units indicates that rheumatic disease is at present the subject of considerable interest: this preliminary report is presented so that other workers in this field may consider including the plasma viscosity estimation among their laboratory methods.

## Technique and Material

The technique of the method is discussed in the Technical Appendix (see p. 688).

The tests were performed chiefly on patients attending the physiotherapy department of Sunderland Royal Infirmary.

Table Showing Plasma Viscosity Findings in Various Conditions

Condition	No. of Tests	Plasma Viscosity*		Average Packed Cell Volume (%)	Average Wintrobe E.S.R. (mm./1 hr.)	Average Total Plasma Protein (g.%)
		Usual Range	Average of Series			
Normal	43	1.700-1.950	1.853	42.9	—	7.15
Fibrositis; myositis	10	1.725-1.950	1.896	46.3	6.7	7.34
Chronic hypertrophic osteoarthritis	17	1.875-2.075	1.921	44.1	8.5	7.31
Rheumatoid arthritis; Residual deformity only	8	1.740-1.990	1.909	41.8	19.8	7.40
Chronic	154	1.950-2.300	2.121	42.6	25.2	7.80
Subacute	22	2.300-2.550	2.512	40.8	36.1	8.50
Acute	16	2.500-3.400	2.897	38.8	38.8	9.54

\* The plasma viscosity is the kinematic viscosity measured at 20° C. and expressed in terms of the calibration of Viscometer V5 as centipoises per g. per c.cm. or cm.<sup>2</sup> per sec.  $\times 10^{-2}$ .

In the past nine months 320\* tests were carried out on cases of rheumatic disease, 200 being cases of rheumatoid arthritis. In addition there were 43 normal controls. In all cases a thorough general medical examination was made to exclude any other pathological process apart from a rheumatic condition.

The diagnosis is the final evaluation of the findings of a team of investigators consisting of a physician, surgeon, radiologist, clinical pathologist, physiotherapist, a biochemist.

## Results

In the absence of an agreed scheme of classification which would allow of statistical comparison we have grouped the cases into the crude groups of (A) rheumatoid arthritis (i) acute, (ii) subacute, (iii) chronic, (iv) residual deformity only; (B) chronic hypertrophic osteoarthritis; (C) fibrositis and myositis. (Our results for Still's disease, rheumatic fever, etc., have been omitted from the accompanying Table and from the discussion.)

We give a few representative cases in detail with outlining our findings for the series as a whole in following general terms (see also Table):

(a) In the early stages of rheumatoid arthritis the viscosity value may still be within range of normal; normal values may be obtained in cases which have responded to therapy.

(b) Progress of the disease processes is usually accompanied by an increase in viscosity, improvement by decrease; the rate of change in viscosity parallels the rate of change in the clinical condition.

(c) In chronic conditions there may be no change in viscosity for several months, although the E.S.R. shows large variations.

(d) There is good correlation between the plasma viscosity value and the clinical picture in rheumatoid arthritis.

(e) The viscosity values for acute, subacute, and chronic rheumatoid arthritis tend to fall, on an average, into distinct zones of the viscosity range (see Table).

(f) Cases of chronic hypertrophic osteoarthritis show viscosity values in the upper range of normality and lower part of the abnormal range (see Table).

(g) In fibrositis and myositis the viscosity is within normal limits.

(h) Our results appear to confirm that the viscosity is a more reliable index of clinical condition than the E.S.R.

## Case Histories

**Case 1: Chronic Rheumatoid Arthritis.**—Female aged Eight years' history of pain and swelling of both knees and proximal interphalangeal joints of the fingers, and pain and limitation of movement of shoulders. Both knee-joints very active, with effusion and increased heat. There was no limitation of movement of the right shoulder. Medical examination revealed no other pathology. Skiagrams of the involved joints showed an atrophic arthritis and those of the chest sinuses were negative. A catheter specimen of urine was negative on culture. Haemoglobin, 82%; W.B.C., 9,600 per c.m. Wintrobe E.S.R., 2 mm. in first hour; P.C.V., 45.7%; total protein, 7.81 g.%; plasma viscosity, 2.045.

**Case 2: Chronic Rheumatoid Arthritis.**—Female aged In 1944 she had pain and swelling of the right elbow-joint, the proximal interphalangeal joints of fingers which lasted for weeks and subsided after a course of physical therapy. November, 1946, she had another attack of pain and swelling in the interphalangeal joints of the fingers, right elbow, shoulder-joint. Examination revealed typical fusiform swelling.

\* The number of cases has now reached 450 without any alteration of the opinions expressed.

the interphalangeal joints of the fingers, with wasting of the *perossei*. The elbow-joint was swollen, and movement was inflexible but full. There was limitation of external rotation and abduction of the right shoulder-joint. Skiagrams of the involved joints showed a typical atrophic arthritis. No focus of infection is found. Hb., 88%; W.B.C., 7,600 per c.mm.; Wintrobe S.R., 6 mm. in first hour; P.C.V., 44.8%; total plasma protein, 7.85 g.%; plasma viscosity, 2.034.

**Case 3: Chronic Rheumatoid Arthritis.**—Male aged 43. General condition very poor. Pain, swelling, and deformity of small joints of hands; swelling and increased local heat in right knee-joint; progressive loss of weight and secondary anaemia. Radiography of chest and sinuses was negative. No focus of infection or any other pathological condition was discovered on medical examination. Feb. 23, 1947: Hb., 75%; W.B.C., 10,600 per c.mm.; Wintrobe E.S.R., 5 mm. in first hour; P.C.V., 41%; total plasma protein, 8.13 g.%; plasma viscosity, 2.270. March 25, 1947: Hb., 80%; W.B.C., 8,500 per mm.; E.S.R., 12 mm. in first hour; P.C.V., 43%; total plasma protein, 8.0 g.%; plasma viscosity, 2.280.

**Case 4: Chronic Rheumatoid Arthritis.**—Female aged 32. Pain and fusiform swelling of proximal interphalangeal joints of fingers; both wrists ankylosed; pain and limitation of movement of right shoulder. The patient had been losing weight rapidly and said the pain was getting worse. Skiagrams of the involved joints showed a typical atrophic arthritis. No focus of infection was found on routine medical examination. Clinically the disease was active, and this finding was supported by Wintrobe E.S.R. of 35 mm., total plasma protein amounting to 8.1 g.%, and a plasma viscosity of 2.095. Four months later, after a period of complete rest in bed, a course of physical therapy, and 0.12 g. of "myocrisin" in weekly injections of 0.1 g., the patient had put on weight, the pain in the joints had greatly diminished, and there was increased movement in the shoulder. The plasma viscosity had now fallen to 1.935, with total protein of 7.8 g.%. The E.S.R. was still 40 mm.

**Case 5: Chronic Rheumatoid Arthritis.**—Female aged 58. Twelve years' history of pain and stiffness in joints. The patient now had flexion deformities of both knee-joints and was unable to walk. She no longer had pain in the joints. Clinically the disease had died out, leaving residual deformities. E.S.R., 20 mm. in first hour; P.C.V., 44.0%; total plasma protein, 7.6 g.%; plasma viscosity, 1.995.

**Case 6: Subacute Rheumatoid Arthritis.**—Female aged 35, Dec. 9, 1946: General condition very poor; signs of activity in small joints of fingers, in knees, and in shoulders. Skiagrams of joints revealed an atrophic arthritis; no focus of infection could be found on routine medical examination. Hb., 65%; W.B.C., 10,600 per c.mm.; Wintrobe E.S.R., 39 mm. in first hour; P.C.V., 39.0%; total plasma protein, 8.5 g.%; plasma viscosity, 2.199. Jan. 21, 1947: After five weeks of treatment, which included three weeks' rest in bed with physical therapy and five weekly injections of 0.01 g. of myocrisin, the E.S.R. was 40 mm.; the P.C.V. 40.5%; the total plasma protein 8 g.%; and the plasma viscosity 2.210. On April 30 the condition was still active and there was marked pain in knees and shoulders. E.S.R., 49 mm.; total plasma protein, 8.9 g.%; plasma viscosity, 2.259. The myocrisin was stopped after a total of 0.12 g. On May 19 the pain was subsiding and in the joints the condition was less active. E.S.R., 40 mm.; total plasma protein, 8.9 g.%; plasma viscosity, 2.250. Here the plasma viscosity increased gradually just as the clinical condition deteriorated. The E.S.R. showed similar changes, but this finding was exceptional.

**Case 7: Chronic Osteoarthritis (Hypertrophic).**—Male aged 50. Complained of pain in both knees; no effusion; marked crepitus in the joints; full but painful movement. Skiagrams showed the changes typical of chronic hypertrophic osteoarthritis. E.S.R., 8 mm. in first hour; P.C.V., 44.4%; total plasma protein, 7.20 g.%; plasma viscosity, 1.979.

**Case 8: Chronic Osteoarthritis (Hypertrophic).**—Male aged 51. In 1938 he sustained a fracture of the upper third of the right tibia involving the knee-joint. Now complaining of aching pain in the joint. No effusion; marked periarthritic thickening; crepitus present; movement full, but painful on full flexion;

gross wasting of quadriceps muscle. Skiagrams showed chronic hypertrophic arthritis. E.S.R., 6 mm. in first hour; P.C.V., 45.0%; total plasma protein, 7.40 g.%; plasma viscosity, 1.920.

**Case 9: Acute Fibrositis.**—Female aged 32. Trapezius muscle very tender and painful, with tender nodules present. Skiagrams of cervical and thoracic spine negative. Responded to five treatments with infra-red radiation. E.S.R., 10 mm. in first hour; P.C.V., 44.6%; total plasma protein, 7.8 g.%; plasma viscosity, 1.820.

**Case 10: Atrophic Spondylitis.**—Male aged 34. Complained of low back pain for several years. There was tenderness over both sacro-iliac joints and marked rigidity of the lumbar spine. Skiagrams showed an atrophic spondylitis. E.S.R., 15 mm. in first hour; total plasma protein, 8.0 g.%; plasma viscosity, 2.184.

### Discussion

✓ The plasma viscosity test is non-specific. It depends entirely upon the plasma proteins, ultra-filtrate experiments having shown the effect of variations in the non-protein constituents to be negligible.

With regard to solutions of the purified protein fractions, in equal concentrations the large molecules of fibrinogen have a proportionately greater effect on the viscosity than those of globulin, and the globulin in turn has a greater effect than the albumin. On the other hand, the three purified fractions appear to affect the specific gravity equally (Nugent and Towle, 1934). Thus a dual test consisting of plasma viscosity and plasma specific gravity frequently suggests which fraction, if any, is markedly increased. Accurate quantitative results cannot, of course, be inferred, for we are now dealing with the highly complex molecular interrelation of native plasma protein (Harkness and Whittington, 1947a), and at present there is no exact knowledge of the physical effects in these circumstances.

While it is not definitely known, it is believed that the liver is the organ which is chiefly responsible for these changes in the plasma proteins—i.e., the plasma viscosity test is a measure of a change in a liver function. The plasma viscosity is a measure of the change in plasma protein which occurs as part of a general systemic reaction to the disease processes in the body: the changes in the joints and soft tissues in rheumatoid arthritis are roughly paralleled by the plasma viscosity changes, indicating that there is a similar parallel systemic upset. We therefore arrive at the conclusion of earlier workers that rheumatoid arthritis is a disease of the whole organism and not merely an affection of the joints.

In striking contrast are the findings in osteoarthritis, where marked changes may occur in a joint without altering the plasma viscosity. Osteoarthritis would thus appear to be a local affection which produces little or no systemic reaction.

As results accumulated, the manner in which similar types of cases gave comparable viscosity results became striking. An apparent paradox arose with a typical osteoarthritis case whose plasma viscosity was 2.535, which was far higher than the expected value (see Table). Clinical reassessment led to the discovery of an early apical tuberculous focus. The necessity of eliminating other possible known causes of disturbance in this non-specific test is obvious.

The variation of serial results in individual cases has proved very useful in estimating progress, and it has been the means of detecting flare-up in chronic conditions. Particularly in the serial tests, the viscosity test is more reliable than the E.S.R.

The plasma viscosity test, on the basis of these first 320 results, would appear to be a promising method of investigation in rheumatic diseases. When further results are

obtained and when serial testing has been carried out for longer periods a more critical evaluation of the method will be possible.

### Summary

The plasma viscosity has been estimated in 320 tests in cases of rheumatic disease and in 43 tests in normal controls. The results of these have been considered generally and some representative cases have been presented in detail.

The plasma viscosity increases with progressive disease in rheumatoid arthritis and decreases with improvement; the increase is roughly proportional to the severity of the disease process; on the whole, the viscosity values for acute, subacute, and chronic conditions tend to fall into distinct zones of the viscosity range.

In osteoarthritis the plasma viscosity values tend towards high normal and low abnormal zones.

Cases of fibrositis and myositis present normal viscosity values.

The general nature of rheumatoid arthritis as contrasted with the local nature of osteoarthritis is discussed.

We wish to thank Dr. Paige Arnold, Dr. H. A. Cookson, Dr. A. A. McIntosh Nicol, and Mr. W. Grant Waugh for their assistance in the clinical assessment of the cases of rheumatic disease.

### TECHNICAL APPENDIX

In the estimation of the kinematic viscosity of plasma it is essential that the viscometer be accurate (at least to the second place of decimals) and that the viscometer be calibrated for colloidal solutions. The high degree of accuracy is necessary because changes of the order of 0.01–0.02 centipoise are clinically significant in the lower range of viscosity values.

Viscometers which measure viscosity by comparison of the time taken by fluids to flow through a capillary will give identical results for monophasic liquids such as water or benzene: with colloidal solutions such as plasma proteins, however, each instrument will give its own characteristic value, depending upon the "shear" of the capillary. In the range of viscosity usually measured in plasma viscosity tests two similar instruments may give results on the same plasma which differ by 0.3 centipoise.

Thus if the significance of viscosity values is to be general and not localized to individual hospitals some method of correlating instruments is necessary. Such correlation has been made successfully (a) by simultaneous estimation of the viscosity of a few plasmas in several instruments, (b) by the comparison of characteristic points of the individual periodic relationships between the plasma viscosity and the maximum E.S.R., as described in detail previously (Houston *et al.*, 1945), and (c) by comparison of the viscosity/concentration line for a solution of a pure protein with the sucrose viscosity/concentration line (Harkness and Whittington, 1947c). Methods (a) and (b) have proved satisfactory for the small number of instruments at present in use, but method (c) will be necessary if this test is used more widely.

All estimations here were made at 20° C. in a Whittington-type viscometer (V6). The results are expressed in terms of instrument V5, the viscometer to which all our instruments are correlated. This modification of the Ostwald viscometer requires only 0.7 ml. fluid and has an experimental error of about 0.2% only. The details of the construction, calibration, and use of this viscometer have been given previously (Houston *et al.*, 1945).

In our original technique sodium citrate solution was used as the anticoagulant, but in the present series it was more convenient to use the potassium and ammonium oxalate mixture of Heller and Paul (1934). This produces no effect on the ratio of cells to plasma as measured by the

haematocrit. This anticoagulant was later recommended for E.S.R. estimations (Wintrobe and Landsberg, 1935) and for the estimation of the plasma specific gravity (Phillips *et al.*, 1945). With this solid anticoagulant fewer laboratory manipulations are required and twice as many tests can be handled daily as with the original method. Owing to the diluting effect of the anticoagulant solution the plasma viscosities of citrate plasma are all much lower than the corresponding viscosities of oxalate plasmas.

### Method

Quarter-ounce (7-ml.) capped bottles are prepared for 5 ml. of blood by evaporating in an incubator 0.2 ml. of solution containing 2% potassium oxalate and 3% ammonium oxalate. To such a tube is added 5 ml. ( $\pm 0.5$  ml.) of venous blood, drawn without stasis. The contents are mixed by gentle rocking so as to avoid the formation of froth. In the laboratory this blood is centrifuged in a graduated tube for half an hour at 3,000 r.p.m. The viscosity estimation on this plasma can be delayed up to about four hours without error.

(a) *Haematocrit: Packed Cell Volume (P.C.V.)*.—While the packing in the wide tube is not maximal an approximate packed cell volume can be calculated from the levels in the graduated centrifuge tube. In dealing with large numbers of tests it was found that the above standardized conditions allowed satisfactory comparison of serial results in the individual cases.

(b) *Plasma Viscosity*.—About 1 ml. of plasma is pipetted out and the viscosity estimation completed. This plasma can be recovered for further chemical tests.

(c) *Total Plasma Protein*.—This is estimated by the copper sulphate specific gravity method of Phillips *et al.* (1945). For the total blood volume as measured in the centrifuge tube the concentration of the anticoagulant can be calculated and allowed for. The plasma protein results so obtained were considered only in the full realization of the possible gross error of the method, as we have reported elsewhere (Harkness, 1947; Harkness and Whittington, 1947b).

Reading a paper on "Smoke and the Public Health" at the Annual Conference of the National Smoke Abatement Society held at Edinburgh on Oct. 1–4, Sir Alexander Macgregor said that further progress towards a cleaner atmosphere might be expected as a result of the increasing application of fuel efficiency methods in industry and in housing. In 1936, 232 tons of smoke were precipitated upon Glasgow as compared with 5 tons at Loch Katrine, and the figure for Glasgow was half of what it had been 30 years ago. In England as much as 500 tons and even 1,000 tons in one place had been recorded as falling on towns. People who worked in a smoke-screen suffered in two main ways: (a) the direct ill effect of breathing smoke-laden air, and (b) the effects of being deprived of sunshine. Smoke had been held to account for some part at least of the higher mortality rate of children under 5 years in pneumonia and bronchitis in the Midland industrial area. It drew attention particularly to the screening off of ultra-violet light by smoke particles, and the necessity of offsetting this effect by adding vitamin D to children's food.

## A CASE OF KERATODERMIA PUNCTATA

BY

BENTLEY PHILLIPS, M.D.

*Honorary Dermatologist, Sutton and Cheam General Hospital*

Keratoderma punctata is a very rare disease. The following case is a good example of it and fulfils the criteria for diagnosis postulated by Sweitzer (1923), who stated that "the true keratoderma punctatum should not show a generalized hyperkeratosis or any erythema at the edges of the lesions." Cleveland White (1930) had a similar case treated by chiropody for twelve years without improvement. My patient had been treated by a chiropodist for two months without success.

## Case Report

A gunner aged 32 was admitted to a general hospital in B.L.A. with a provisional diagnosis of "? multiple verrucae of hands." After examination and investigation keratoderma punctata was diagnosed. The patient had had no previous

illnesses or skin disease, and had always been healthy. He was a farmer in civil life and had had four years' service as an infantryman before joining the artillery. The family history was completely negative.

Three months before admission he noticed small hard "lumps" developing in the creases of his palms and on the inner borders of his feet. There was slight pain on walking and on pressure, and the lesions were described by the patient as "plugs which remained for about a week, then dropped out, and new plugs developed." There was no history of his having taken arsenic or any other drug. He was of good physique, and nothing abnormal was discovered in

FIG. 1.—Photograph showing crateriform pits, some of which are filled with horny plugs.

FIG. 2.—Enlarged photograph of actual lesions.

any of the systems. The urine was normal; the Kahn test negative. The general skin condition was normal.

**Hands.**—Multiple small crateriform pits, some empty and some filled with greyish-black horny plugs, were found, entirely limited to the creases of the palms. Generalized hyperkeratosis was not present. Each lesion was surrounded by normal skin and there was no erythema. On the left hand the majority of the lesions were situated in the two distal creases. There were fewer lesions on the right hand, and a number of grouped puncta were situated at the inner end of the distal crease. This group was removed for a biopsy and the report stated: "Hyperkeratosis only. No inflammatory changes present."

**Feet.**—A few grouped lesions were found on the inner borders of the soles of the feet. The skin apart from these lesions was normal. There was no hyperkeratosis, clavus, or other abnormality.

FIG. 3.—Photomicrograph of one of the lesions, showing hyperkeratosis only.

The patient was treated with a keratolytic application—ung. acid. salicyl., 15%, applied thrice daily—with some improvement. He was returned to duty as there was little or no disability.

My thanks are due to Colonel H. J. G. Wells for permission to publish this paper, and to Lieutenant-Colonels F. F. Hellier and G. B. Mitchell-Heggs, O.B.E., for their interest and observations on the case.

VITAMIN K FOR THE RELIEF OF  
CHILBLAINS

BY

D. P. WHEATLEY, M.B., M.R.C.S.

Chilblains consist of a reaction to cold in susceptible persons. The predisposing factors in such people are assumed to be defective peripheral circulation, with increased permeability of the vessel walls and diminished coagulability of the blood. Such is the description given by MacKenna (1937). It would seem logical, therefore, to treat such a condition with a substance which will correct these abnormalities. In vitamin K we have such a substance, for in avitaminosis K the same abnormalities are present and are corrected by the administration of the vitamin.

Stewart and Rourke (1939) showed that hypoprothrombinaemia results from lack of vitamin K and that the prothrombin level in such cases could be restored to normal by the vitamin. Scarborough and Macfarlane (1942) pointed out that hypoprothrombinaemia gave rise to a delayed coagulation time, and concluded that a capillary defect might also be present in that condition. A somewhat similar state of affairs occurs in the allergic manifestation known as urticaria. Black (1945) studied the prothrombin level in a number of cases of chronic urticaria and found it diminished in 65%. He also found that the condition could be relieved by vitamin K therapy, the most marked improvement, in fact, occurring in those cases with lowered prothrombin level.

On these considerations is based the following small series of cases. Unfortunately, it was not possible to estimate

the prothrombin times in these cases; and the results are based on clinical observations alone. The prolonged spell of severe weather last winter afforded a unique opportunity for assessing the efficacy of the treatment. A commercial preparation of acetomenaphthone, synthetic vitamin K, was used throughout.

### Case Reports

*Case 1.*—A man aged 37 had suffered from chilblains ever since he could remember. He was engaged on outdoor work, which aggravated them. He had tried numerous remedies, including calcium in various forms, a variety of ointments, and a full course of concentrated vitamin D injections, without effect. All his fingers and toes were swollen and dusky red, with signs of ulceration on several of the toes. He was given a single intramuscular injection of 5 mg. of acetomenaphthone. When seen one week later he was ecstatic, saying that for the first time he had obtained relief from his symptoms. His fingers were normal, and the toes showed only a slight residual swelling. A course of 10 mg. orally twice daily was instituted. By the end of a further week all trace of chilblains had disappeared. He was not seen again for two months, when he came up voluntarily to express his admiration of the treatment. During this time he had received no further vitamin K and had continued with his outdoor work. The chilblains had not recurred, and on examination there was no sign of any. The only symptom was a slight tingling in the toes of a few days' duration; this rapidly disappeared with a further course of the drug.

*Case 2.*—A Continental married woman refugee aged 30 had never had chilblains before coming to England. Now she has them all the year through, in a state of continual ulceration. She had tried all the usual treatments—calcium, vitamin D by mouth and injection, and injection of concentrated vitamin D, etc.—with no effect. All her fingers were grossly swollen, reddened, and ulcerated at most of the joints. She was given 5 mg. of synthetic vitamin K by intramuscular injection. Eight hours later the swellings had greatly subsided, although the ulcerations remained unaffected. Unfortunately the injection caused a great deal of pain, and she declined to have more. Instead, a course of 20 mg. orally twice daily was instituted. The patient was seen two weeks later, when there was some duskeness of the fingers and slight ulceration. The swellings, however, had completely subsided and the remaining ulceration was far less than it had been. In addition, there was now no irritation. A month later, however, during which time she had continued treatment, the fingers had again ulcerated and were again irritable; this coincided with the severe weather conditions. Nevertheless, the lesions were not nearly so bad as they had been at first, when the weather had not been particularly cold.

*Case 3.*—A married woman aged 28 had for the last seven years suffered from chilblains on her toes each winter. Last winter they had come on with particular severity and had invaded her heels and even the backs of her legs. They were present most of that season, with acute exacerbations during cold spells. When seen she was undergoing one of these exacerbations, and the back of the lower half of each leg was covered with several large, raised, reddened chilblains. They were not ulcerated, but were giving rise to intense irritation. She was given 20 mg. of acetomenaphthone thrice daily; the first dose was taken in the morning, and by the evening the irritation had ceased. Previously this had been constantly present. She was seen four days later, during which time there had been no irritation, and she was highly delighted with the result. The chilblains on her legs were still present, although there was a definite diminution in redness and swelling. Treatment was continued, and for a week she was free of symptoms. Then, however, the severe cold set in and the irritation started again, although there was no swelling, only dusky bluish patches in the skin. She was advised to continue with the treatment in spite of this setback. Unfortunately, she failed to attend again, and so further results were not known.

*Case 4.*—Personal observations. In this case mild chilblains occur in cold weather only. They never ulcerate, but give rise to intense irritation, most pronounced on going from a cold atmosphere to a warm one. They always clear up with milder weather. The patient, being somewhat averse to intramuscular

injections, had an oral course of 20 mg. of vitamin K daily. After five days of this the chilblains had disappeared. Unfortunately this test coincided with a change in the weather, it was not conclusive. Soon afterwards, however, the weather again became very cold, and this spell lasted for several months and so it was possible to make more conclusive observations. To begin with, 20 mg. were taken twice daily before the chilblains had had time to develop. This did not prevent their appearance, but their onset occurred much more slowly and with much less irritation than before. After five days the doses were increased to thrice daily, and after a further five days irritation had ceased and the swellings had almost subsided. The doses were decreased to twice daily as before, and further trouble was experienced for three weeks. At the end of this time the irritation restarted, so doses were again taken thrice daily and the symptoms cleared in a few days. A maintenance dose of 10 mg. daily proved insufficient to prevent recurrence of symptoms within a few days. Again these were cured by the larger doses, which were continued for the rest of the cold weather—about five weeks, during which time further symptoms were encountered.

*Case 5.*—A married woman aged 21 had some moderate severe chilblains on her toes and heels last winter for the first time. These cleared up after a few days' treatment with vitamin K (20 mg. twice daily) and did not recur on cessation of treatment.

*Case 6.*—A woman aged 21 had had chilblains on her toes and heels every winter for the past four years. They were of moderate severity, but gave rise to such intense irritation that she dared not go very close to a fire for fear of aggravating them. She was sceptical that any treatment could give relief, but, to her surprise, after one week of vitamin K (20 mg. twice daily) her symptoms were greatly relieved and the swellings much reduced. Treatment was continued, but the patient failed to keep any further appointments.

*Case 7.*—A French girl aged 19 had suffered from chilblains since coming to this country several months previously. She had never had them before, and ascribed them to her inadequate diet during the German occupation. Her fingers were affected and were much swollen, but her toes were free. After one week's treatment (20 mg. twice daily) there was little improvement. For the second week bile salts were administered with the vitamin K, and there was now some improvement, the swellings being smaller and bluer. There was, however, no further improvement at the end of a third week, although she considered her symptoms to be somewhat better.

*Case 8.*—A man aged 46 occasionally suffered from chilblains in the winter. When seen he had moderate chilblains, together with infected corns, on his toes only. He was given 20 mg. vitamin K twice daily and his chilblains disappeared in three or four days and did not recur, although he took only one week's course of the treatment.

### Discussion

In this small series of cases the administration of vitamin K would definitely seem to have exerted a favourable influence on the condition known as chilblains. The dosage appears to vary from individual to individual, and is not related to the severity of the condition. On an average a dose of 20 mg. twice daily was found most generally useful. Again, in some cases a short course of treatment was sufficient to give protection for a long period, whereas in others it was necessary to continue the dosage to prevent recurrence of the lesions.

Howell (1941) suggested that prothrombin and fibrinogen might be constantly formed and consumed in the blood, the result being the formation of fibrin, which in some ways might provide nourishment or protection for the cells of the capillary walls. It was on this assumption that the work on urticaria was done.

Might it not be that in chilblains there is a similar impairment of this mechanism, with resultant damage to the capillary walls—the cause in this case being cold rather than allergic stimulus? The individual susceptibility might

explained by a mild hypovitaminosis-K in certain individuals. Kark and Lozner (1939) showed that this hypovitaminosis could in fact occur in adults owing to causes other than liver disease. In any case it would seem worthwhile giving vitamin K a further trial in this widespread and irritating condition.

### Summary

The treatment of eight cases of chilblains, ranging from the mildest manifestation to severe and ulcerated forms, is described. In four there was complete alleviation of symptoms and signs, the response in Case 1 being exceptionally good. In the other four there was an improvement. Two of these patients defaulted before treatment was completed, so the final result as not known. In the remaining two there was improvement, specially of the actual chilblains, although the pernicious condition of the digits remained; and in one there was a recrudescence of symptoms in spite of continued treatment.

As regards the mode of administration it was considered that intramuscular injections were superior to the oral route. They were, however, accompanied by considerable pain, so they had to be abandoned, as the patients were not prepared to put up with this for the possible cure of their relatively minor ailment.

## CALCIUM DEPOSITS IN THE IRIS IN A CASE OF SECONDARY HYPERPARATHYROIDISM

BY

C. PONIÉDEL, M.B., Ch.B.

Late Senior Physician, Ministry of Pensions Childwall Hospital,  
Liverpool

The following case is of interest for two reasons: (a) a review of the literature does not reveal any previous reference to such deposits in these cases; (b) renal calculi and metastatic calcification were absent from the kidneys.

Oliver (1939) refers to three cases of hyperparathyroidism, as follows. (i) Dawson and Struthers (1923). A man aged 49 with a long history of multiple fractures, ending in syncope and death; necropsy showed a parathyroid tumour, calcification of vessels (heart, lungs, kidney, liver, spleen). (ii) Lowenburg and Ginsberg (1932) describe the case of a boy aged 5 who received an overdose of parathormone, 100 units daily for 6 days, with resultant vomiting and listlessness after two days, followed by mental depression and high fever. Blood examination on the sixth day showed serum calcium 19.6 and blood phosphorus 4.4 mg. per 100 ml. On withdrawal of the drug the patient became normal. (iii) Hanes (1939) mentions a woman aged 49 who complained of weakness, pains in the legs, and loss of weight. Previous radiography of the kidneys, when in hospital for pyelitis, had shown diffuse fine mottling. Serum calcium was 12 mg. per 100 ml. and renal functions were markedly impaired. Five years later, on final admission to hospital, she had a tumour of the lower pole of the thyroid. Blood calcium was 20 mg., phosphorus 4.7 mg., phosphates 23 mg., and non-protein nitrogen 58 mg. per 100 ml. Skiagrams showed metastatic calcification in the kidneys and decalcification of bones. The patient became weak, depressed, and febrile, and she soon died. Necropsy showed a necrotic partly calcified parathyroid tumour.

Moore (1943) states that calcification had been reported in many organs in hyperparathyroidism, but not in bone-marrow. He mentions calcification in kidney, stomach, heart, liver, and marrow found in experiments on animals. Werner (1942) describes metastatic deposits in the kidney, and says they can occur in other organs and tissues (none mentioned specifically). He also quotes Allbright, Baird, Cope, and Bloomberg for renal calculi; and Dawson and Struthers as finding calcium infiltration in practically every organ of the body. Jaffe (1940) states that secondary parathyroid hyperplasia is found more regularly in connexion with chronic renal insufficiency than in any other condition, and that the hyperfunction becomes severe enough to induce pronounced skeletal and other tissue changes, the chief lesions being skeletal and renal (calculi). Nephrosclerosis is less common. Severe renal insufficiency is followed by calcification in soft parts (subcutaneous tissues and arteries).

### Case History

The patient had a history of having been taken ill in October, 1944, while serving in the East. At that time he complained of loss of weight, loss of appetite, frequency of micturition, and looseness of the teeth. He was admitted to hospital, where the urine was found to be of low specific gravity and to contain albumin and hyaline and granular casts. Skiagrams of the kidneys, after intravenous "uroselectan," failed to reveal the outline of any renal tissue. The blood urea was 140 mg. per 100 ml.

In November, 1944, he became drowsy and the skin dry. At this period he developed a left-sided Bell's palsy; and the ear-drums were found to contain chalky deposits. Soon afterwards vision became blurred, and examination revealed a chalky deposit in the anterior chamber of the right eye and retina—choroidal atrophy. By this time the rough skin showed nodularity, which appeared to be due to chalk-like deposits. Blood examination revealed a serum calcium of 17 mg. and inorganic phosphorus of 4.3 mg. per 100 ml.; the phosphate index was normal. Radiology of the long bones showed widespread osteoporosis.

By February, 1945, the serum phosphate was 22 units (normal 3–13), and a diagnosis of hyperparathyroidism was made. Blood calcium and blood urea could be controlled temporarily by reducing intake of phosphates. The blood calcium fell to 11 mg. and the blood urea to 82 mg. per 100 ml., only to rise again in two weeks. Primary hyperparathyroidism was considered to be the diagnosis.

In June, 1945, the urine volume was 3½ pints (2 litres) daily, S.G. 1012 or less. Urea clearance was 30% of normal, and the blood urea 80 mg. per 100 ml. X-ray investigation showed well-marked calcification of the peripheral vascular tree in places. His general condition had improved, although wasting of the legs was extreme, and the diagnosis of primary hyperparathyroidism was thought to be incorrect because of the normal serum phosphates, absence of urinary calculi, and absence of skeletal weakness (neither fractures nor bowing of long bones).

In February, 1946, the patient was admitted to Childwall Hospital for review. On admission he complained of loss of balance when walking. He was emaciated and there were calcium deposits beneath the nails. Disks and ear-drums were as on previous occasions. In addition the irises showed fine deposits of calcium. Urea concentration was 1.3%, and faeces calcium 60% (normal reading 80% to 90%). Skiagrams of arteries showed slight calcification in the walls of the arteries of both hands, and those of the skull, spine, and long bones revealed generalized slight osteoporosis. Blood calcium amounted to 14 mg., blood urea 52 mg., serum albumin 4.5 mg., serum globulin 1.5 mg., and inorganic phosphate 3.5 mg. per 100 ml. The phosphate index was normal; there was a secondary anaemia with moderate eosinophilia. Examination of the urine showed protein 1%; sodium chloride, 6.5 mg. in 24 hours; calcium oxalate ++, hyaline casts +, and a few granular casts; red cells were occasionally present.

*Progress of the Case.*—Owing to the emaciation present it was considered advisable to put the patient on a fuller diet about

mid-March. His blood urea kept about 60 mg. per 100 ml. and his progress was satisfactory. However, on April 3 he was found to be strange in manner and unresponsive when questioned, and further probing showed that he was suffering from delusions. A diagnosis of uraemia was made and he was given glucose and fruit drinks up to 3 pints (1.7 litres) a day and a diaphoretic mixture; the bowels were attended to, and he also received 1/2 gr. (32 mg.) phenobarbitone s.o.s. He slept well that night and was rational the next day. The blood urea reading was 86 mg. per 100 ml. on April 3, and had fallen to 66 mg. the following day. The blood calcium was 11 mg. per 100 ml. (normal). He usually passed 20 oz. (568 ml.) of urine by day and 26 oz. (740 ml.) at night when receiving normal diet and fluids. This indicated a lack of concentrating power of the kidneys. Shortly afterwards he took his discharge from hospital against advice.

On March 8 the patient had developed auricular fibrillation, which responded to digitalis treatment, the drug being discontinued a month later. His pulse remained regular and the heart steady.

### Comment

The evidence was in favour of a diagnosis of primary chronic renal disease with secondary increase of calcium in the blood. The fact that the blood calcium had become normal was against a primary hyperparathyroidism, as it is usually stated that without operation a primary condition of the parathyroid would not improve. Price mentions that hyperparathyroidism occasionally occurs as a result of chronic nephritis.

Interesting points were (1) the presence of deposits in the irises; (2) the absence of renal calculi; (3) a temporary attack of auricular fibrillation associated with uraemia.

I wish to thank the Director-General of Medical Services, Ministry of Pensions, for permission to publish this article.

## BABCOCK'S OPERATION FOR THORACIC ANEURYSM

BY

F. T. RANSON, M.B., F.R.C.S.Ed.  
 Shanghai

The operation described by Babcock (1926; 1932) consists of an anastomosis between the common carotid artery and the internal jugular vein of one side. Former operations for these aneurysms had used the principles of reduction of flow of blood through the sac or else the introduction of foreign bodies into the sac. Babcock's operation is based on the principle of speeding up the flow of blood through the sac and thus reducing the pressure of blood inside the aneurysm.

I have had the opportunity of performing this operation in eight cases. The patients were all male Chinese with aneurysms eroding the anterior chest wall; all complained of severe pain and all had a positive Wassermann reaction.

### Method

The operation is performed as follows. Under local anaesthesia a transverse incision is made in the neck (usually right side) about 1½ in. (3.75 cm.) above the clavicle. The sterno-mastoid muscle is cut across and the common carotid artery and internal jugular vein are dissected out and

cleaned. Both vessels are ligated high up, and umbilical tapes are placed around them low down so as to control bleeding. The vessels are divided just below the ligatures and the heart ends are anastomosed. After slowly releasing the tapes and seeing that the anastomosis is watertight the wound is closed.

McCarthy (1930) in an excellent detailed article on the subject discusses the hydromechanics of the operation. Half the circulation to the head is short-circuited back into the heart, and this removes the resistance of all vessels above the anastomosis. Added to the removal of this resistance is the aspiration effect exerted by venous suction. This results in lowered pressure and increased blood velocity inside the sac.

McCarthy uses the analogy of the garden hose with a weak place in its wall. If the water pressure is high and if the spigot of the hose is partially obstructed, the hose will tend to bulge at the weak spot. If, however, the spigot is opened widely, the pressure inside the hose will be reduced, the velocity of the water increased, and the bulge will tend to subside.

### Results

Whatever happens inside the aneurysm, there is one striking immediate result of the operation, and that is relief of pain. This disappearance of pain took place in all but one of my cases and was remarked on by the patient immediately after release of the controlling tapes.

Of the eight patients seven left the hospital improved and relieved of pain. The eighth, who had a swelling as big as a fist on the chest wall, died of external rupture of the aneurysm five days after operation. He had not experienced any relief of pain.

In a personal communication in 1946 Babcock wrote "I have now performed between 26 and 30 of these operations. As some have felt that the relief is due to the division of fibres connected with the carotid plexus, I have had opportunity to note the effect upon pain in four cases of large abdominal aneurysms in which an anastomosis was made between the heart ends of the external iliac artery and vein. In the abdominal cases it was possible to see the effect of the operation upon the aneurysm characterized by a prompt partial collapse of the sac immediately after the systolic wave, showing that prolonged systolic tension was not possible with the large leak back into the veins that had been established. The relief from pain was also striking, particularly in one patient who had required large doses of morphine at frequent intervals before the operation and had complete relief after operation." The operation is an easy one to those familiar with the technique of vessel suture.

At a surgical meeting in Chicago I heard the procedure described by an eminent and thoughtful surgeon as unjustified. It cannot be expected to cure the patient, but surely it is something to be able to relieve his pain, and this is often a distressful feature of these cases.

The only other operation for thoracic aneurysm of which I have had experience is wiring, but I have not observed any relief of pain with this method.

The Central Office of Information has produced two films on child psychology for parents. The first, "Children Learning by Experience," is a study of children learning in their own way and was designed for teachers in training to provide material for discussion. The second, "Children Growing up with Other People," depicts children's development towards a balance between individualism and co-operativeness.

## Medical Memoranda

### Case of Traumatic Recto-Vesical Fistula

he means and methods of producing impalement of the rectum are various. It has been said that they are more common in country districts owing to accidents with pitchforks and by persons being tossed on the horns of bulls. Perforation by the ivory enema nozzle, formerly said to be common in midwifery cases, provides another type of case, which has now become rare since rubber catheters have replaced the nozzles.

Cases of traumatic recto-vesical fistula are not common. They may be followed by chronic invalidism due to persistent cystitis, pneumaturia, and diarrhoea. The case described was caused by a plant stick, and since then I have heard of no other case produced by a bamboo cane supporting a tomato plant.

#### CASE REPORT

A schoolboy aged 7 was playing in the garden when he slipped on some steps and sat down forcibly on a thin stick supporting a hyacinth plant. The stick passed through his trousers and entered the anus. The child's cry brought his mother to the spot and she took him immediately to her doctor. On examination the doctor found no bleeding from the rectum, no abdominal tenderness, and nothing abnormal on rectal examination. The child had by now recovered from his fright and did not complain of pain or discomfort. In view of this the doctor sent him home and told his mother to report should anything abnormal develop.

The boy continued in perfect health for five days. He had no pain and passed both urine and faeces normally. On the fifth and sixth days he had diarrhoea, passing loose liquid yellow motions. He also had some frequency of micturition, but there was no pneumaturia. On the seventh day the patient still had diarrhoea and now had complete retention of urine, and screamed every time he attempted to pass it. The doctor advised removal to hospital.

When first seen at the hospital the child was found to have a greatly distended bladder almost up to the umbilicus, with slight abdominal tenderness confined to the lower abdomen, and rectal examination was too painful to be carried out without an anaesthetic. Rectal examination was therefore carried out under gas-and-oxygen anaesthesia, and immediately there gushed forth a large quantity of foul-smelling yellow fluid which was obviously infected urine. When the rectum was completely emptied the walls were palpated, and anteriorly a small hole slightly larger than a quill was felt. This hole connected with the bladder. A rubber catheter was tied into the bladder and the urine drained continuously.

On the third day after admission the patient's bowels were opened normally and there was no diarrhoea. Motions continued to be normal until the seventh day after admission, when the catheter was removed; he then passed urine normally.

The patient was kept under observation for another week, during which time both urine and faeces were passed normally. There was no recurrence of the diarrhoea and no pneumaturia. The temperature had remained normal throughout, and the pulse, which was raised at first, was now restored to normal. At the end of the week the patient was discharged. Follow-up has shown that the boy continues in good health and has normal micturition and defaecation.

#### COMMENT

In view of the curved course of the rectum it is unlikely that any pointed object will enter it with force and not penetrate its wall. The clinical history and signs will vary with the size of the perforation.

In cases with small perforations, as above, inflammatory oedema may obstruct the hole: Pinnock (1937) describes a case in which the tear was neither seen nor felt. The value of proctoscopic examination, however, should not be overlooked. The only constant features of traumatic recto-vesical fistula are retention of urine and foul-smelling diarrhoea coming on about the seventh or eighth day. In cases of larger perforations these symptoms may be present from the first, but they definitely get worse at the end of the week. This is confirmed by Breyer (1933) and Galbraith (1937). Pain is not a common feature, as the mucous membrane is sensitive only for 1½ in. (3.75 cm.) up from the anus.

This case demonstrates that a small perforation may be cured by the simple means of passing a catheter and keeping the

bowels confined for a few days. The catheter should be left in until the stools have been normal for four or five days. Larger tears will need more active surgical procedure.

I wish to express my thanks to Prof. A. Rendle Short, of Bristol Infirmary, for permission to publish this case.

### Traumatic Valvular Pneumothorax

The following case of traumatic valvular pneumothorax came under my care and typically illustrates the real surgical emergency of the condition. I am prompted to hope it may be worthy of record.

#### CASE REPORT

During a landing exercise at sea a rating was accidentally shot through the left chest by a 0.22 bullet at approximately 150 yards range. He walked several hundred yards from the spot, returned half a mile by sampan to the ship, and unaided made his way to the sick bay, where he instantly collapsed. It was two minutes later when I saw him, supported in a chair, mouth open, and violently throwing his limbs about in a vain attempt to breathe. He was extremely cyanosed, with neck, left shoulder, and chest grossly swollen. The entrance wound was just medial to the middle of the left scapula with the exit wound directly superior to the mid-clavicular point. A rapid examination elicited an obvious subcutaneous surgical emphysema, cardiac displacement, hyper-resonance, and absent breath sounds over the greater part of the left lung. Two lumbar-puncture needles, without time for aseptic precautions, were plunged into the left pleural cavity, one high up anteriorly and the other posteriorly, resulting in the immediate escape of air and an initiation of jerky respiration. Rubber dams were fixed over both wounds and multiple small cruciate incisions made in the neck and upper chest to alleviate the surgical emphysema which was helping to push the trachea over to the right and further obstruct the existing embarrassed breathing. The patient was then put to bed, propped up, and given 1/4 gr. (16 mg.) of morphine, which with reassurance and warmth soon counteracted the excitement and shock. Within half an hour he was asleep but considerably restless: breathing was shallow and regular, the cyanosis had largely disappeared, and the pulse had dropped from 140 to 90. Owing to the restlessness the needles had to be removed. Portable x-rays revealed a large pneumothorax and dulling of the costo-phrenic and cardio-phrenic angles.

He gradually improved for several hours, but then his condition again began to deteriorate and it was decided to perform a more elaborate operation. Under local analgesia a trocar (of copper) and cannula (a steel pin), made on the spot by the engineers, was inserted through the second intercostal space 1½ in. (3.75 cm.) from the sternum, and a thin-bore soft rubber catheter threaded through and connected to a water-sealed bottle of weak antiseptic to effect a slow continual drainage of air from the pleural cavity. By now there had developed acute abdominal pain, with tenderness, rigidity, and boarding especially in the left hyperchondrium; this was treated with hot applications. Next morning the patient felt comfortable, both chest and abdominal pain having largely subsided; breathing was easier, and in general his condition was satisfactory.

He was admitted to hospital on return from sea. Both wounds were excised and drainage was stopped after 36 hours, from which time he made an uninterrupted recovery.

#### DISCUSSION

Only the smaller bronchioles could have been involved, and the initial shock must have been well compensated owing to the relatively long active interval before treatment, response to which was most dramatic and noteworthy. The abdominal pain and boarding presumably were the result of the small haemothorax irritating the diaphragm, coupled with the pressure of the pneumothorax. Fortunately no sepsis set in and the patient was discharged, fit for light duty, three weeks later with only a very small and diminishing pneumothorax present. One interesting feature is a resultant weakness of his left arm. All movements are fairly good but incomplete, and he cannot bear weight satisfactorily, although a slow improvement is taking place. There is no evidence of muscle wasting. The complication is undoubtedly the result of direct contusion of the brachial plexus by the actual bullet, in combination perhaps with some pressure involvement from the surgical emphysema.

## Reviews

### RENAL CIRCULATION

*Studies of the Renal Circulation.* By Joseph Trueta, M.D., A. E. Barclay, D.M., P. M. Daniel, M.B., K. J. Franklin, D.M., and Marjorie M. L. Pritchard, M.A. From the Nuffield Institute for Medical Research, Oxford. (Pp. 187; 83 illustrations. 25s.) Oxford: Blackwell Scientific Publications. 1947.

This is an unusual book, for it is written more in the form of a narrative than in that of a scientific communication. We learn of the researches (one almost said the adventures) of a team of workers who were led on from an angiographic investigation of the reaction of arteries to trauma into an intimate study of the renal circulation. We cannot escape the infectious enthusiasm of the authors as we read how they first suspected that in certain circumstances the renal blood flow might be largely diverted from the cortex to the medulla, and how the mechanism and anatomy of this shunt were investigated and demonstrated by various beautiful techniques. Fascinating pictures, faultlessly reproduced, illustrate the narrative.

This manner of presenting a major piece of research makes for easy and pleasant reading and leaves one in no doubt that the authors consider their work to be of fundamental importance. It is therefore necessary to examine their claims rather closely. In our view they are fully justified. They have demonstrated beyond any reasonable doubt the existence of a circulatory shunt in the mammalian kidney, a fact which must from now onwards be taken into account in any consideration of renal physiology and which may compel us seriously to modify our interpretation of modern clearance tests. They have shown how unlike in structure are the nephrons of the outer cortex from those of the juxta-medullary zone, and how this difference of structure must signify difference of function. They have thrown new light on the peculiar anatomy of the vasa recta and given us a glimpse into the possible purpose of their unique design. They have suggested obvious lines of approach towards the understanding of such conditions as reflex anuria, cortical necrosis, and the action of certain drugs and nervous stimuli on the kidney, the implications of which must be far-reaching.

With respect, we would offer two criticisms. The first is that the narrative style, although it is well suited to those who want instruction, is inadequate to presenting concrete information to the serious worker who would like to confirm the results and initiate new investigations. We should like to see a series of shorter papers giving protocols of experiments and more details of technique, written up in conventional scientific form. Secondly, we think the authors go too far at this stage in their claim that the shunt mechanism may explain the origin of human essential hypertension. The possibility may properly be suggested, but we think with more reserve than the authors seem to show, for much work remains to be done. Even studies of renal function and blood pressure under varying conditions of renal circulation have yet to be made. The greatest merit of this important work is that the authors propound new techniques and new ideas with which they and others will be able to pursue researches for many years to come. To say only that is high praise indeed.

ROBERT PLATT.

### OBSTETRICS

*Textbook of Obstetrics.* By Gilbert I. Strachan, M.D., F.R.C.P., F.R.C.S., F.R.C.O.G. (Pp. 732; 323 illustrations and three coloured plates. 45s.) London: H. K. Lewis and Co.

A new textbook of obstetrics must arouse interest in these days when thought and practice in midwifery are undergoing considerable changes, and one written with the authority and experience of Prof. Strachan is opened with eager anticipation. As might be expected, it is a thoroughly sound piece of workmanship, well produced and liberally supplied with unusually good illustrations. It is more comprehensive than most books designed for undergraduates, but it conforms to the usual pattern. Dr. A. G. Watkins and Dr. R. L. Drummond contribute chapters

on the newborn child and on blood transfusion respectively. The author unhesitatingly expresses his own opinions, formed after long experience, and also gives an account of many other views and methods. Throughout he lays well-merited emphasis on the need for a conservative outlook in obstetrics and on the general efficiency of natural processes. All will agree with this and many will also approve of the orthodoxy which is a keynote of the book. Others, however, may consider that it would have been improved if it had been less traditional in some respect and if some of the older, even standard, views and methods had been subjected to criticism or had been omitted. The factual information is up to date, and so complete an account of midwifery cannot fail to attract a large number of readers, not only among undergraduates but among graduates seeking further information or studying for higher diplomas.

T. N. A. JEFFCOATE.

### CEREBRAL PALSY

*A Way of Life for the Handicapped Child. A New Approach to Cerebral Palsy.* By Eirene Collis. With foreword by Somerville Hastings, M.B., F.R.C.S., M.P., and an introduction by Winthrop M. Phelps, M.D., F.A.C.S. (Pp. 183. 10s. 6d.) London: Faber and Faber. 1947.

Mrs. Collis, who may be regarded as the pioneer in the treatment of cerebral palsy in Britain, has performed a valuable service in writing this book, which is based on her experience over a number of years in this country and the U.S.A. The educating of these children is slow and laborious and often no appreciable results may be seen for years. Mrs. Collis points out that the team workers engaged in educating and re-educating children with cerebral palsy must possess two main qualities—namely, interest and proper humility. The team, which consists of physiotherapists, occupational and speech therapists, school teachers, and others, must approach the problem of the child as a whole, so that both the mental and bodily aspects can be dealt with at the same time. The author also rightly stresses the importance of a favourable environment for the child, since much of the good work can be undone by mishandling on the part of the parents or other guardians.

The author clearly defines the various types of cerebral palsy and she draws attention to the means of recognizing the condition in the early years of life, for obviously the sooner treatment is begun the more benefit does the child obtain from it. She makes no extravagant claims, for, as she points out, the children are taught to "substitute." By this is meant teaching the child to do with the healthy parts what he cannot do with the injured. Faulty movements are corrected and the child is re-educated to use his muscles rightly by means of physiotherapy (which includes aids such as skis and special chairs) and occupational and speech therapy. Mental education is attended to at the same time by school work, hygiene, and removing emotional disabilities by correcting the environment.

The book can be recommended to all who are interested in this difficult problem and especially to those concerned with the education of backward and crippled children.

LOUIS MINSKI.

### DEVELOPMENTS IN BIOCHEMISTRY

*Currents in Biochemical Research.* Edited by David E. Green. (Pp. 486. \$5.00.) New York: Interscience Publishers, Inc. (215, Fourth Avenue).

In 1937 a group of investigators, all of whom had received inspiration from the late Sir Frederick Gowland Hopkins joined together under the leadership of Dr. J. Needham and Dr. D. E. Green to produce a volume of essays of a speculative nature entitled *Perspective in Biochemistry*. This volume was published in honour of Hopkins's seventy-fifth birthday. Ten years later Dr. D. E. Green, now returned to the U.S.A., has gathered together a group of research workers who have provided "thirty-one essays charting the present course of Biochemical Research and considering the intimate relationship of biochemistry to medicine, agriculture, and social problems." In his editorial preface Dr. Green makes no reference to the earlier volume, of which, however, the present book may be regarded as a direct descendant.

The authors are almost entirely from the U.S.A., and the subjects are as follows:

The Gene and Biochemistry, by G. W. Beadle; Viruses, by W. M. Stanley; Photosynthesis and the Production of Organic Matter on Earth, by H. Gaffron; The Bacterial Cell, by René J. Dubos; The Nutrition and Biochemistry of Plants, by D. R. Hoagland; Biological Significance of Vitamins, by C. A. Elvehjem; Some Aspects of Vitamin Research, by Karl Folkers; Quantitative Analysis in Biochemistry, by Donald D. Van Slyke; Enzymic Hydrolysis and Synthesis of Peptide Bonds, by Joseph S. Fruton; Metabolic Process Patterns, by Fritz Lipmann; Biochemistry from the Standpoint of Enzymes, by David E. Green; Enzymic Mechanisms of Carbon Dioxide Assimilation, by Severo Ochoa; Hormones, by B. A. Houssay; Fundamentals of Oxidation and Reduction, by Leonor Michaelis; Mesomeric Concepts in the Biological Sciences, by Herman M. Kalkar; Viscometry in Biochemical Investigations, by Max A. Lauffer; Isotope Technique in the Study of Intermediary Metabolism, by D. Rittenberg and David Shemin; Mucolytic Enzymes, by Karl Meyer; Some Aspects of Intermediary Metabolism, by Konrad Bloch; The Steroid Hormones, by Gregory Pincus; Plant Hormones and the Analysis of Growth, by Kenneth V. Thimann; Chemical Mechanism of Nervous Action, by David Nachmansohn; Some Aspects of Biochemical Antagonism, by D. W. Woolley; Chemotherapy: Applied Cytochemistry, by Rollin D. Hotchkiss; Biochemical Aspects of Pharmacology, by Arnold D. Welch and Ernest Bucding; Some Biochemical Problems Posed by a Disease of Muscle, by Charles L. Hoagland; Physiology and Biochemistry, by Surgeon Captain C. H. Best; X-ray Diffraction and the Study of Fibrous Proteins, by I. Fankuchen and H. Mark; Immunochimistry, by Michael Heidelberger; Social Aspects of Nutrition, by W. H. Sebrell; Organization and Support of Science in the United States, by L. C. Dunn.

As might be expected from such a diverse group of authors the essays are of an uneven standard, but all are stimulating and sometimes provocative. Each is a survey in clear language by an expert research worker of the important developments in his own field, with some speculation on the most likely paths of future progress. It is a pity that, unlike its predecessor, this volume has no index, since the inclusion of at least a subject index would have greatly added to its value. However, the book achieves its author's aim of assisting those interested in the subject to see biochemistry in clearer perspective and in its proper relationship to other fields of inquiry. This volume is highly commended to all those who wish to learn about the present rapid developments in biochemistry.

F. G. YOUNG.

## THE LOUSE

*The Louse. An Account of the Lice which Infest Man, their Medical Importance and Control.* By Patrick A. Buxton, C.M.G., F.R.S. (Pp. 164. 10s. 6d.) London: Edward Arnold and Co. 1947.

This new edition of Prof. Buxton's monograph will be widely welcomed. Though the first edition appeared only in 1939, recent research has necessitated increasing the size of the volume by nearly half as much again. The author presents much new knowledge of the sensory physiology of the louse and of its behaviour, particularly in relation to the host, and recently obtained information about the incidence of the insect. A useful addition is a very full account of the recent work on the insecticides such as D.D.T. which have revolutionized louse control. Prof. Buxton also includes a short account of obsolete or obsolescent methods for the sake of completeness.

It is to be hoped that the present conditions hampering the publication of medical books are only temporary. More than two years elapsed between the completion of this manuscript and the final appearance of the volume in the bookshops. Such delays are a great disadvantage to research workers waiting for new information to be made available and they must often cause a new book to be out of date before it appears. Fortunately Prof. Buxton's book has scarcely suffered in this way, for he was actively concerned with the work he describes and thus was able to include a certain amount of previously unpublished information. However, perhaps one effect of the lapse of time has been to reduce the bibliography, since the author has been unable to include references to some recent British papers on louse control whose publication was delayed by security measures. American references consequently preponderate, since there has been less hesitation in the U.S.A. about publishing information considered to be secret.

KENNETH MELLANBY.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Dr. Samuel Gullrie: Discoverer of Chloroform.* By J. R. Pawling, M.D., M.A., F.A.C.P. (Pp. 123. No price.) Watertown, N.Y.: Brewster Press. 1947.

A biography, with many illustrations, of the American chemist and physician.

*The Fever Bark Tree.* By M. L. Duran-Reynals. (Pp. 251. 8s. 6d.) London: W. H. Allen. 1947.

The story of malaria and the search for quinine.

*Skin Manifestations of Internal Disorders.* By Kurt Wiener, M.D. (Pp. 690. 63s.) London: Henry Kimpton. 1947.

The author describes and illustrates with numerous photographs the skin manifestations of many internal disorders.

*Bovine Tuberculosis.* By John Francis, B.Sc., M.R.C.V.S. (Pp. 220. 25s.) London: Staples Press. 1947.

A monograph on bovine tuberculosis with a detailed comparison between the disease in cattle and in man.

*Transactions of the Association of Life Insurance Medical Directors of America.* 55th Annual Meeting. Edited by H. E. Ungerleider, M.D. Vol. XXX (Pp. 378. No price.) New York: Recording and Statistical Corporation Press. 1947.

Includes papers on rheumatic fever, exploratory electro-cardiograms, thrombosis and anticoagulants, and peptic ulcers.

*A Textbook of Gymnastics.* By K. A. Knudsen. Vol. I. 2nd ed. (Pp. 384. 15s.) London: J. and A. Churchill. 1947.

The author describes and discusses the "form-giving" exercises of the Ling system.

*Drugs from Plants.* By T. I. Williams, B.A., B.Sc., D.Phil. (Pp. 119. 6s.) London: Sigma Books, Ltd. 1947.

An account for the general reader of some drugs obtained from plants.

*Progress in Gynecology.* Edited by J. V. Meigs, M.D., and S. H. Sturgis, M.D. (Pp. 552. 35s.) London: William Heinemann. 1947.

A collection of papers on recent advances in gynaecology intended particularly to refresh the minds of those returning to practice after the war.

*Getting Ready to be a Mother.* By Carolyn C. Van Blarcom, R.N. New English edition edited by Gladys B. Carter, B.Sc., S.R.N., S.C.M. (Pp. 311. 8s. 6d.) London: Macmillan and Co. 1947.

How to prepare for and care for the baby; intended for laymen.

*Poisons: Their Isolation and Identification.* By Frank Bamford, B.Sc. 2nd ed. revised by C. P. Stewart, M.Sc., Ph.D. (Pp. 304. 21s.) London: J. and A. Churchill. 1947.

Intended as a laboratory manual for chemists who have to deal with cases of poisoning.

*Mental Health.* By John H. Ewen, F.R.C.P.Ed., D.P.M.; and C. Friedman, M.D. (Vienna), L.R.C.P.&S.Ed (Pp. 270. 12s. 6d.) London: Edward Arnold and Co. 1947.

A brief account of mental disorder intended for the medical student and practitioner, as well as those concerned with social and educational problems.

*Morphologic Hematology.* Special Issue No. 1 of *Blood*. Edited by William Dameshek, M.D., et al. (Pp. 200. \$4.75.) New York: Grune and Stratton. 1947.

Includes papers on the bone marrow, Hodgkin's disease, phagocytosis, and blood platelets.

*A Textbook of Histology for Medical Students.* By Evelyn E. Hewer, D.Sc. 4th ed. (Pp. 407. 21s.) London: William Heinemann. 1947.

A practical textbook for the medical student; this edition includes a new chapter on protective mechanisms.

*Essays on Contemporary Events.* By C. G. Jung. (Pp. 90. 8s. 6d.) London: Kegan Paul. 1947.

Includes three essays on the state of Europe to-day, and a lecture on the problems facing psychotherapists at present.

## BRITISH MEDICAL JOURNAL

## FOOD CUTS AND VITAMINS

Last week Sir Stafford Cripps announced that the average daily food intake per head will be less and involve a reduction of calories from 2,870 to 2,700. The Government's experts<sup>1</sup> have estimated that 2,700 calories "per head per day are probably too low." Energy requirements obviously differ, and what is enough for a labourer is probably too much for a clerk. Although exact knowledge is still lacking, it is probable that the intake of first-class protein is too small to allow any margin of safety. Cuts in any food items are naturally reflected in a smaller variety of dishes and an added strain on the housewife, and so probably in less efficient utilization of what food there is. The drought has reduced the milk supply, and a severe winter may once more interfere with the supply of spring vegetables. Yet we are clearly not starving, and there is little evidence that the health of the people of the country is suffering as a result of a tightened belt. With a reduced variety of food and the shortage of things like bacon, eggs, milk, and meat, the practitioner will ask himself, and will no doubt be asked by his patients, whether there is any risk during the coming winter of deficiency in vitamins. Does our present diet, in fact, leave only a small margin of safety—a margin that can be kept only by the most intelligent buying on the part of the housewife? If there is a risk of deficiency in this, that, or the other vitamin, it is a risk that can be covered by the manufacturing chemist. So that the practitioner may have available up-to-date information on vitamins, we have invited Dr. L. J. Harris to give an extended answer to a question that came in for the "Any Questions?" Section of the *Journal*. The other question that must arise in many minds is whether there will be any justification for the widespread prophylactic use of vitamins, apart, of course, from the special instances of nursing mothers and young children.

Though our diet has since 1939 been restricted, its general pattern has not been changed. Before the war our diet, on the whole, was fairly well chosen by those who could afford to choose it well, and since 1939 attempts have been made, in spite of the inevitable restrictions, to correct its faults. The main danger, if we consider only measurable quantities, has been that we should not get enough food to provide the calories we need—now at a level "probably low."

The Ministry of Food has published<sup>2</sup> estimates based on the amounts of imported and home-produced foodstuffs of the average amounts of nutrients consumed per head. According to these estimates the amounts of vitamins and of iron and calcium have risen or changed but little. However, the faith of the most credulous in these

statistics must be shaken by the assertion that we were eating more animal protein in 1946 than before the war. The results of surveys of consumption by representative families made each month by the Ministry of Food conform more with our experience—not unnaturally. These results are withheld from public scrutiny. However Drummond in 1946 published the results of survey carried out in the summers of 1943, 1944, and 1945, and from these we may estimate the average level of our diet.

Working-class families were found to be receiving about 2,700 and middle-class families about 3,000 i.u. of vitamin A a head a day. These figures are rather higher than would be expected, for a normal adult gets under 1,000 i.u. of pre-formed vitamin A; and the usual helping of vegetables, other than carrots and kale, supplies under 1,000 i.u. (if, as is now the accepted practice in this country, the vitamin A value of  $\beta$ -carotene is taken as 1 i.u. per 0.6  $\mu$ g). The Accessory Food Factors Committee in 1945 considered that 3,000 i.u. a day is sufficient. Although the average intake was less than this, the rations of butter and milk assured a regular basic intake; very low intakes must have been much less common than they were before the war.

There has been no danger of vitamin B<sub>1</sub> deficiency since white flour and polished rice were eliminated from our diet and the amount of sugar was reduced. The increase in amount of niacin obtained from flour when the rate of extraction was raised has compensated for that lost by the reduced consumption of meat. With the increase in liquid milk available the average intake of riboflavin has risen. In 1943–5 the average intake of these three B vitamins was more than that agreed for the new standards of the National Research Council of the U.S.A. The vitamins of the B group are found together in foodstuffs; if the food contains enough of the three major members of the group it will contain enough of any other members of the group. According to *Food Consumption Levels*<sup>2</sup> the average intake of ascorbic acid has been higher than before the war, but no allowance was made for losses in cooking. Since the war started the proportion of ascorbic acid derived from fruit, which is eaten raw or loses little vitamin C in cooking, has fallen, and a larger proportion is obtained from vegetables, which lose some three-quarters of the vitamin in cooking. These estimates, therefore, do not indicate the changes in the amounts actually consumed. The actual intakes of ascorbic acid were much less than the figures given in Drummond's table, because he also made no allowance for losses in cooking. During the summer and autumn, when potatoes are fairly new and fruit and vegetables plentiful, the average intakes are satisfactory. But during the first four months of the year, when the amount of ascorbic acid in potatoes is small and other vegetables and fruit are scarce, the average intakes fall very low. The amount of calcium ingested rose with the increased consumption of milk. The apparent total, as shown in Drummond's table, was about 0.1 g. above daily requirement though about 0.1 g. of this total calcium was not absorbed because of the large amount of phytic acid in the flour. The total iron available was also more than required.

These average figures look well enough, but distribution is not even; certain groups rightly have first call on

<sup>1</sup> *Food Consumption Levels in the United States, Canada, and the United Kingdom*. H.M.S.O. 1944. 2s.

<sup>2</sup> *Food Consumption Levels in United Kingdom*. H.M.S.O. 1947. Cmd. 7203. 6d.

valuable foodstuffs. "Ordinary" adults get only 2 pints (1.14 l.) of milk a week during a considerable part of the year. They can obtain only 0.25 mg. of riboflavin a day from milk products, now the chief source, and cannot make up their estimated requirements from meat as they could before the war. They cannot get much more than 1.2 mg. a day, the limit below which signs of riboflavin deficiency may be expected. Milk and milk products have always been the chief source of calcium, but 2 pints of milk a week supply only 0.19 mg. a day. The changes in food supply since 1945 have not greatly altered our intake of vitamins. The cheese ration is now 1 oz. (28 g.) a week less, which reduces the vitamin A intake by 50 i.u. and riboflavin by 0.02 mg. a day. The cut in the meat ration reduces riboflavin by a further 0.02 mg. With the usual scarcity of vegetables and an unusual scarcity of potatoes we shall be getting very little vitamin C in the first four months of next year.

We do not know how much health will be affected by this shortage. It is true that in such studies as those of Bransby and his colleagues<sup>3</sup> there was no evidence that such low intakes impaired health in any way; and the effects of complete deprivation of vitamin C have been cured by daily doses of about 10 mg. of ascorbic acid. But we do know that, unless more fruit can be obtained, our average intake will be well below any of the accepted standards of requirement. With such a narrow margin of safety it may be thought advisable to take extra vitamin in the form of concentrates. There is no evidence that reasonable doses of vitamins A, D, or C can do any harm. But the implication of Marion Richards's experiments<sup>4</sup> is that the ingestion of large amounts of one member of the B group, while the intake of other members remains low, may induce signs of deficiency of these other members. It is therefore advisable to take supplements of the B group in the form of yeast or wheat-germ preparations, which contain all the members, rather than preparations of isolated vitamins. There is no sign that our food will become more appetizing, and the danger remains that people may eat too little simply because they do not like the food they get. There is no reason why education should not effect a change in habits, and why people should not be taught to make their food as appetizing as possible. Owners of gardens or allotments should be encouraged to grow vegetables—root vegetables if not greens—especially for the early part of the year. Flour is an important source of the B vitamins, and any attempt to interfere with its quality in order to make it whiter should be resisted.

## GERMAN TROPICAL MEDICINE

During the earlier part of this century many important advances in tropical medicine were due to German research workers. Their wartime handling of various problems in this field is now revealed in a series of reports by the Combined Intelligence Objectives Subcommittee.<sup>5</sup> The German forces were distributed over the globe less widely

than those of the British and Americans, and their main contacts with tropical diseases, notably malaria, typhus, and dysentery, were in the Mediterranean area and in South Russia. All soldiers were immunized against smallpox, typhoid, and paratyphoid A and B. Other inoculations were also given at various times—for example, against cholera on the Eastern Front in the early years of the war, until it was discovered that this infection was not likely to be widespread.

Malaria was controlled chiefly by mepacrine (atebrin). Apparently this drug was preferred as much from lack of quinine supplies as from any realization of its superior effectiveness. The dosage, based on British pre-war experience in Malaya, was fixed at 0.4 g. weekly, divided into daily doses of 0.06 g. This had no toxic effects, but it was believed to prevent only about two-thirds of the clinical malaria which would otherwise have occurred. The Australians achieved more complete suppression of malaria in New Guinea under much more severe exposure. Their greater success may have been due to the higher dosage employed (0.1 g. daily) or, perhaps more likely, to their strictness in ensuring daily administration. The Germans, in spite of their traditionally rigid discipline, could not enforce this daily dose of mepacrine with the same regularity. There was a general feeling among German malariologists that the administration of pamaquin (plasmoquin) at the end of a therapeutic course of mepacrine lowered the subsequent relapse rate. They had little convincing evidence on the subject, however, and it is doubtful whether the amount they gave (0.02 g. daily for three days) could have had much effect. Little attempt was made during the war to introduce new antimalarial drugs. Although sontoquin<sup>6</sup> had been discovered by the I.G. Farbenindustrie workers about 1938 and was given to some 1,000 patients during the war, there was no attempt to bring it into general use, partly because of the manufacturing difficulties, partly because it was not considered to have any great advantage over mepacrine. Sontoquin (SN 6911) is a 4-amino-quinoline compound, one of a series which has been intensively studied and developed in America, the most favoured member of the group being chloroquin (resochin, SN 7618).<sup>7</sup> D.D.T. derivatives were applied in the later years of the war, apparently on a limited scale, to control mosquitoes. Some clumsy attempts were also made at the Dachau concentration camp to produce immunization by semi-controlled attacks of malaria. This work, involving 1,200 prisoners, was under the direction of Dr. Klaus Karl Schilling, the eminent malariologist, who was subsequently hanged.<sup>8</sup>

The most important infection which the Germans had to deal with was typhus. Soon after the occupation of Poland three institutes were set up there for the preparation of typhus vaccine by means of Weigl's louse-culture technique. Smaller amounts were produced later by the mouse-lung and egg techniques (the last of which was most favoured by the British and Americans), but louse-culture provided their main supply throughout the war. "Sterile" hatched lice were maintained under semi-aseptic conditions for fifteen days. They were then inoculated with typhus

<sup>3</sup> Bransby, E. R., et al., *British Medical Journal*, 1946, 1, 193.

<sup>4</sup> Richards, M., *ibid.*, 1945, 1, 434.

<sup>5</sup> *Combined Intelligence Objectives Subcommittee Reports*, 24, 5: 27, 97; 28, 55; 29, 13, 35.

<sup>6</sup> *British Medical Journal*, 1946, 2, 267.

<sup>7</sup> *J. Amer. med. Ass.*, 1946, 130, 1069.

<sup>8</sup> *British Medical Journal*, 1947, 1, 148.

rickettsiae by inserting a fine glass cannula into the anus. The lice were maintained for a further five days, after which the intestines were removed by dissection and used for the preparation of the vaccine. These two operations, inoculation and dissection, require highly skilled technicians. A good worker with his assistant and a dissecting microscope can inoculate nearly 1,000 lice in an hour, and can dissect up to 2,000 a day. At all stages the lice must be fed on human subjects, since non-human blood is poisonous to them. Usually the feeding is done by holding a small cage of lice against the skin. After inoculation with typhus rickettsiae the lice are infective and only immune subjects can be employed. The Institute at Cracow kept 2,000 Polish subjects for this purpose, and, as they received rather better treatment than the ordinary civilian population and obtained some protection against the Gestapo and similar agencies, there was no difficulty in obtaining volunteers. A single person can feed 10,000 lice daily, losing about 10 ml. of blood in half an hour. Material from 30 to 100 lice was required to complete the inoculation for each soldier. It was calculated that the cost of this material was about 1.8 reichsmark or about 3s. at pre-war rates. The original orders to these three institutes were to produce sufficient vaccine to immunize 2 million men in 1940. One million lice were constantly maintained at Cracow, but later there seems to have been a shortage of vaccine, for another report states that typhus immunization was used only on the Eastern Front, and then it was given only to men over 35 or to those exposed to special risks. The effectiveness of the vaccine was investigated by the S.S. on 150 prisoners, who were all infected with typhus. The disease was not completely prevented by the vaccine, but its course was much less severe and resembled a mild attack of influenza. Of these prisoners 35 had been kept as unvaccinated controls, and 33 died; the other two were fortunate in having had a previous attack of typhus. No drug treatment of typhus came into general use during the war, although a nitro-acridine compound called "rutenol" was shown in the laboratory to have a marked curative action in animals infected with *R. mooseri*.

Bacillary dysentery caused much trouble, particularly in Poland in 1939 and in North Africa. Treatment by sulphonamides, especially sulphapyridine, was eventually introduced, although much later than in the Allied forces. Compulsory vaccination was given against this infection from 1942 to 1944 but was abandoned later because the results were entirely negative. Amoebic dysentery occurred to some extent in North Africa. Cases were treated mainly with di-iodoquin ("enterovioform") by mouth and by emema, apparently with satisfactory results. Emetine was not available in quantity. Schistosomiasis was of no importance for the German Army, but post-war interrogations have shown that laboratory work had produced a new chemotherapeutic remedy, "miracil," which seems promising. So far it has been tested only in animals, in which it is remarkably effective against *S. mansoni*. On the whole, these reports about German work on tropical medicine show many interesting details but few real advances in fundamental knowledge.

## NOBEL PRIZE FOR MEDICINE

The Nobel Prize for medicine for 1947 will be shared between Prof. B. A. Houssay, of Buenos Aires, and Prof. Carl F. Cori and Dr. Gerty T. Cori, of St. Louis, U.S.A. The latter are receiving their share for research "on the course of the catalytic transformation of glycogens," and Houssay his share for "his discovery of the importance of the frontal lobe of the hypophysis in sugar metabolism." Professor Houssay was present at the Physiological Congress at Oxford a month ago, and the present award will be especially welcome in view of the treatment he has received in his own country. Just about a year ago Dr. Houssay, who was Professor of Physiology in the Faculty of Medical Sciences, was relieved of his post in the University of Buenos Aires. According to *La Prensa*, which recorded the fact of Dr. Houssay's dismissal, this was followed by a boycott of the physiology classes by Dr. Houssay's pupils, and by the voluntary resignation of a number of his colleagues indignant at the treatment he had received. We understand that Dr. Houssay was dismissed for political reasons. When the dismissal took place Dr. E. Braun Menéndez, Deputy Professor of the Faculty of Medical Sciences, resigned in order "to reaffirm his solidarity with Professor Houssay, recently relieved of his post, an exemplary master, who with his talent, his work in research and his self-denying dedication to his work has brought honour to the chair of Physiology in the Faculty of Medical Science of Buenos Aires and to the country, deserving without any doubt the respect of posterity." This respect has now been sealed by the award of the Nobel Prize. The year, too, Oxford University gave Houssay an honorary D.Sc. and the Royal Society made him a Foreign Member.

## INVESTIGATION INTO POLIOMYELITIS

It was announced in our Epidemiological Notes (Oct 2 p. 677) that two large-scale investigations of this year prevalence of poliomyelitis are in progress. One is a hospital inquiry undertaken by the Ministry of Health in order to secure more accurate estimates of the fatality and severity of the disease in the present epidemic. The number of cases confirmed as poliomyelitis may be smaller than the number of notified cases, for it has been estimated in some places that one-third or even one-half of those notified were not in fact cases of poliomyelitis.

The other investigation is being carried out by medical officers of health in certain areas. It has been organized at the request of the Ministry of Health by the Public Health Laboratory Service, which is directed by the Medical Research Council. It was initiated in the counties of Berkshire, Buckinghamshire, and Oxfordshire, where orthopaedic out-patient clinics are provided by the Wingfield Morris Orthopaedic Hospital, Oxford. The plan in these counties is to undertake an epidemiological investigation of cases of poliomyelitis and poliio-encephalitis during 1947 and the next few years. A questionnaire was drawn up on the basis of the one used in the Mauritius epidemic of 1945 (McFarlan, Dick and Seddon,<sup>1</sup> and the help of the Institute of Social Medicine was enlisted to ensure that the data would be collected in a form suitable for analysis on the Powers machines there. The questionnaire covers some social and environmental factors as well as such details as age, sex, date and place of onset, and possible source of infection. After completion of the field investigation by the medical officer of health the forms are sent to the Public Health Laboratory, Oxford, where they are examined for any suggestion that cases in different districts shared

<sup>1</sup> *Quart. J. Med.*, 1946, 16, 183.

source of infection which was not evident in the individual cases and which deserves further investigation. The forms are then sent to the hospital, where the diagnosis is checked and some clinical details are recorded. Finally the forms are sent to the Institute of Social Medicine for analysis. The same questionnaire is being used by medical officers of health in some other parts of the country for a survey of their cases with such arrangements for the completion and collection of the forms as suit local conditions. It is expected that the pooling of accurate data from several health districts will yield information which cannot be obtained from individual districts, particularly if cases are few. In some areas which are participating in the survey independent inquiries are being made, and it is to be hoped that the results of these and other investigations will be published as early and as fully as possible.

It is encouraging to know that many people are endeavouring to record the epidemiological features of the 1947 prevalence of poliomyelitis in England and Wales and in Scotland. Virus work on selected cases is being done at the Central Virus Laboratory of the Public Health Laboratory Service, and clinical studies may be expected in addition to those published by Kelleher<sup>2</sup> and McAlpine<sup>3</sup>. Accurate observation and documentation provide the data on which sound epidemiological theory and reasonable preventive measures must be based.

### CENTENARY OF CHLOROFORM ANAESTHESIA

The ill luck and indeed tragedy that clouded the lives of many who played a part in the discovery of anaesthesia were misfortunes that James Young Simpson was fortunate enough to avoid. The centenary of his discovery of the anaesthetic properties of chloroform is the subject of an article at p. 701 by Dr. Douglas Guthrie. About a year ago Morton's demonstration of the anaesthetic properties of ether in 1846 was commemorated in different parts of the world and was the subject of articles in this *Journal*.<sup>4</sup> Since then the story of anaesthesia has been told by various authors.<sup>5-7</sup> Henry Hill Hickman, who experimented on inhalational anaesthesia in 1824, was rejected by his contemporaries and died at the age of 30. John Elliotson, who hypnotized his patients—or, as he put it, mesmerized them—into insensibility was forced by the action of the Council of University College Hospital to resign from his post as physician. Crawford Long gave ether as an anaesthetic in 1842, but escaped fame by not publishing what he did. Horace Wells in 1844 showed that with nitrous oxide teeth could be extracted painlessly, and a year later was unsuccessful when he tried to demonstrate the anaesthetic properties of nitrous oxide in the Massachusetts General Hospital. The quarrels over priority between Wells, Morton, and Jackson unhinged Wells's mind, and after being sent to prison for throwing acid on the clothes of some New York street-walkers he committed suicide in 1848. C. T. Jackson, who tried to "jump the claims" of Morton, ended his life in a lunatic asylum. Morton himself, who was the hero of the celebrations last year, finally became mentally unstable and died in hospital a short time after he had plunged into a lake.

James Young Simpson, of tougher fibre, came through the ordeal of discovery with flying colours, though he, too,

had his fair measure of fierce opposition—an opposition which fittingly in Scotland was based on biblical evidence. But Simpson did not discover chloroform, which was first produced in 1831 by Guthrie in America, Soubeiran in France, and Liebig in Germany, each working independently. According to J. R. Pawling,<sup>7</sup> Guthrie was the first of these three to produce chloroform. He thought it might be valuable as a medicine, but seems to have been impressed by its virtue as an intoxicating drink. It became known locally as Guthrie's "sweet whiskey," and in a letter to his daughter in February, 1848, he wrote: "I could have made a fortune if I had gone to New York as I was urged last fall by making sweet whiskey. . . ." Simpson, who had used ether to relieve the pains of childbirth, was constantly on the lookout for a new anaesthetic, and the hint that chloroform might be worth trying was made to him by Dr. David Waldie; with Keith and Matthews Duncan, Simpson sniffed the vapour from tumblers in his room at 52, Queen Street, Edinburgh, on Nov. 4, 1847. Simpson's account of his use of chloroform as an anaesthetic was published at about the same time in the *Lancet*, the *London Medical Gazette*, and in the *Provincial Medical and Surgical Journal* (the precursor of the *British Medical Journal*). But Simpson seems to have been preceded by others.<sup>8</sup> In the summer of 1847, for example, William Lawrence, surgeon to St. Bartholomew's Hospital, was practising with a new anaesthetic agent called "chloric ether," a solution of chloroform in alcohol, but he published no account of his experiments. And still earlier Jacob Bell, in a footnote in the *Pharmaceutical Journal*, noted the use of "chloric ether" as an anaesthetic in February, 1847—apparently it was tried at the Middlesex Hospital. In February, 1847, too, Flourens anaesthetized "an animal forced to breathe the vapour of chloroform." It is, therefore, not accurate to describe Simpson as the discoverer of the anaesthetic properties of chloroform. Nevertheless, his vigorous advocacy of this drug and his energetic campaign for the relief of the pains of childbirth secure him an unassailable place in the history of anaesthesia. And in acclaiming him for this we should not omit to mention the man who introduced the scientific method into anaesthesia and who gave Queen Victoria chloroform at the birth of two of her children—John Snow, whose portrait Barbara Duncum has put as a frontispiece to her valuable book.

### CARCINOMA OF THE PENIS

The subject of cancerous and precancerous lesions of the penis has recently been reviewed by Melicow and Ganem<sup>1</sup> in connexion with a report of 23 cases. The essential features of cancer of the penis are well known. It is not a common disease; it occurs chiefly after middle life, and it is almost unknown among Jews who practise ritual circumcision. The cancerous process may be secondary to some antecedent local disease such as leucoplakia, the erythroplasia of Queyrat, Paget's disease, or Bowen's disease. The exact importance of such antecedent disease is difficult to determine, and in only two of the 23 cases now reported was there histological proof of its existence. An associated phimosis and infection are present in the majority of patients who develop cancer of the penis, and in fact chronic balanitis in middle life should be regarded as a potentially malignant condition. The precise effect of the retained and infected smegma is uncertain, but it may be that on decomposition it produces carcinogenic hydrocarbons or sterols. Bowing, Fricke, and Counseller<sup>2</sup> reported an antecedent recent circumcision in 34.8%

<sup>1</sup> *British Medical Journal*, 1947, 2, 291.

<sup>3</sup> *Ibid.*, Oct. 12, 1946.

<sup>4</sup> *The Development of Inhalation Anaesthesia*. Barbara M. Duncum. 1947. Published for the Wellcome Historical Medical Museum by Oxford University Press. Price 35s.

<sup>5</sup> *Victory over Pain. A History of Anaesthesia*. Victor Robinson, M.D. Sigma Books, London. Price 16s.

<sup>6</sup> *Dr. Samuel Guthrie, Discoverer of Chloroform*. J. R. Pawling, M.D. 1947. Brewster Press, Watertown, New York.

<sup>7</sup> *J. Urol.*, 1946, 55, 486.

<sup>8</sup> *Radiology*, 1934, 23, 574.

of their series of 195 cases of carcinoma of the penis, but the probability is that the malignant process was actually present at the time of the circumcision. In this connexion an unhealing circumcision scar in an adult should always be viewed with suspicion. The local penile disease usually starts on the glans at the corona, either as an external papillary excrescence or as an indurated ulcer, and it may have been preceded by a precancerous lesion which was not discovered on account of the phimosis. The lymph drainage is into the superficial inguinal glands, the deep inguinal glands, and the external iliac glands, and owing to the free anastomosis of the penile lymphatics there may be deposits in the inguinal glands on the opposite side to the primary lesion. The urethra is involved only in late cases, and abdominal metastases are rare. The disease may also spread by extension via the dorsal vein of the penis.

Diagnostic difficulties may be great on account of the association of phimosis, balanitis, and cancer, and at times it may be impossible to determine clinically whether or not a malignant process is actually present. Biopsy of the primary growth or biopsy of the inguinal glands by puncture may be useful if frozen sections are available and immediate operation can be carried out. There is still considerable difference of opinion on the best method of treatment, but the treatment in the individual case must be determined by the patient's age, the size and nature of the lesion, the involvement or not of the corpora cavernosa, the presence of inguinal metastases, and the importance and site of any superimposed infection. Partial or complete amputation of the penis with bilateral resection of the inguinal glands is the method of choice. The safety of the operation should be greatly increased by modern methods of controlling infection. Local recurrence of the penile growth is unusual. There is still, however, great difference of opinion on the value of irradiation in treatment. Circumcision and personal hygiene are the only two prophylactic methods which are likely to reduce the incidence of carcinoma of the penis, but there will be no general support for the authors' contention that routine circumcision should be carried out in babies in order to prevent the development of penile cancer.

### INDIUM

The high price of indium still limits its application, but the entire world stock, which exceeded 2 tons in 1934 and was chiefly held in America, has been considerably augmented since 1940, and its use in electroplating, as a constituent of alloys for dental prosthesis, in jewellery manufacture, and in the radio and television industry may extend greatly in the coming years. Animal experiments have already shown that given by mouth its toxicity is low. The dosage for man equivalent to that which produces poorly defined subnormal states in animals would be about 123 gr. (8 g.), but the quantity of indium which dissolves in acids makes its use in metal food-containers undesirable.<sup>1</sup> Its irritant property, as tested on human skin by the wearing of indium-treated silver plates, is not sufficient to constitute any industrial hazard.<sup>2</sup>

It is toxic, however, when injected into animals subcutaneously or intravenously. If amounts sufficient to cause death are injected the organ most severely affected is the liver, and there is evidence also of renal damage. In some recent animal experiments,<sup>3</sup> where the dosage given produced "subacute" poisoning allowing survival of the animals for three to six days, the lesions observed were selective, affecting the liver, kidneys, heart, and submaxillary glands, but sparing the pancreas, testes, suprarenals,

brain, and parotid glands. The type of lesion was not less specific—the degeneration was hyaline and parenchymatous in character, never fatty or pigmentary. Thus, in the liver the hyaline degeneration, leading eventually to necrosis, was sometimes vesicular or hydropic. In the kidneys some of the tubules were completely necrosed while others remained unaffected. In the heart the characteristic lesion was hyaline transformation of the striated muscle fibres. Only rarely, as by contact with lacerated tissues, will the effects of indium on man be in any way comparable to those noted in animals receiving subcutaneous injections. Yet because such conditions might occur in industry indium cannot be dismissed as completely harmless, and it is useful to know what lesions might be produced in the remote eventuality of gross overdosage.

### TREATMENT OF UNDULANT FEVER

Undulant fever is one of the diseases the treatment of which has been little, if at all, affected by the introduction of sulphonamides and antibiotics. There have, indeed, been reports of recovery after sulphonamide therapy, but in many other instances it has proved ineffective, and the recoveries were probably coincidental. The experimental administration of sulphonamide drugs to infected guinea-pigs has shown that they can eliminate the infection, but only when given in doses so large as to approach, or pass the toxic level.<sup>1, 2</sup>

Huddleson,<sup>3</sup> however, has recently reported that when non-inhibiting high dilutions of many sulphonamide compounds are added to liquid culture medium containing *Brucella* sensitizing antibody in high dilutions and complement then the organisms are inhibited and killed. This occurs not only *in vitro* but also *in vivo*. Guinea-pigs infected with *Brucella* organisms can be freed of infection by the oral administration of normal doses of sulphonamide drugs combined with the injection of weak antiserum, such as normal rabbit serum. From the serum of animals so treated Huddleson has isolated the sulphonamide drug and the antibody in combination, and he believes that the effect of the drug is to potentiate the bactericidal action of antibody plus complement.

It is a little difficult to understand why an injected weak antiserum, potentiated by a sulphonamide drug, should have a bactericidal effect, while the serum of an infected animal or man, often of a high agglutinating titre, has no effect. Huddleson explains this on the basis of the Neisser-Wechsberg phenomenon—a serum may be bactericidal in high dilution yet not in low dilution. Having successfully treated infected animals, Huddleson applied the method to four patients suffering from undulant fever. They had all been ill for a considerable time and were being given sulphonamide drugs. He advised that the dosage should be reduced and that they should be given blood transfusion. No special care was exercised in the selection of the donor, it being assumed that all normal human blood contains bactericidal *Brucella* antibody. The treatment was carried out and the four patients soon recovered.

Huddleson's observations may prove of fundamental importance and have wide application. Meanwhile it would be of interest if others would repeat, and report on this suggested treatment of undulant fever. The administration of small doses of sulphonamide drugs (sulphadiazine or sulphamerazine is recommended) together with blood transfusion can hardly do harm, and any treatment which holds out a hope of cure of this refractory disease is to be welcomed.

## CENTENARY OF CHLOROFORM ANAESTHESIA

BY

DOUGLAS GUTHRIE, M.D., F.R.C.S.Ed.

*Lecturer on History of Medicine, University of Edinburgh*

A year ago the birthday of ether anaesthesia was duly and fitly celebrated the world over. The discovery in 1846 of ether as an anaesthetic was the climax of an age-long search. That it was so long delayed is truly remarkable. Many a time down the ages it had been so nearly found. There had been the nepenthe of Helen of Troy, which brought forgetfulness of every sorrow; the mandragora of Dioscorides, which remained in use until the Renaissance; the physical methods, such as pressure on nerves or freezing, which have been strangely revived in modern times; and the mesmerism for which John Elliotson fought so hard and which was the favoured line of anaesthetic research at the time when ether appeared on the scene and, in the words of Robert Liston, "beat mesmerism hollow."

In a few days the birthday of chloroform anaesthesia will be celebrated, and some may wonder why we should not simply honour the American pioneers of ether anaesthesia, and leave it at that. Was not chloroform simply another anaesthetic? Yes, but it was more. Just as Lister discovered not carbolic acid but the antiseptic method, so did Simpson, eighteen years earlier, discover not only chloroform anaesthesia but an anaesthetic method. Anaesthesia became a science under Simpson's guidance.

### James Young Simpson

It is advisable to give some account of his life work, familiar as it must be to many readers. Born at Bathgate, Linlithgowshire, in 1811, James Simpson was the son of a baker whose family was large while his resources were small. Jamie seems to have been an unusually bright child, filled with that insatiable curiosity and desire for knowledge which marked the youth of John Hunter and many another genius. The family resolved that Jamie should have a good education, and from early boyhood he was marked for the medical profession. He was still a youth when his parents died, but the paternal care was continued by his elder brother Sandy, while his sister Mary became to him a second mother. When he entered Edinburgh University he was "very poor, very solitary, and almost friendless," but he soon showed his worth, graduating M.D. in 1832. An incident of his student days turned his attention to anaesthesia: it was during his attendance at an operation—and very little imagination is required to enable one to picture the horrors of surgery without anaesthesia and the agony endured by the central figure on the table. James Simpson's whole soul revolted at the sight as he left the Infirmary and sped towards Parliament House, resolved to exchange the profession of medicine for that of law. Success would have followed him there, or indeed anywhere. On second thoughts, however, he determined that he would try to relieve pain instead of running away from it. The opportunity was soon to come. It was John Thomson, the professor of pathology, whom he assisted,

who suggested to Simpson that he might do well to specialize in obstetrics. Thomson himself had tilled many fields—anatomy, military surgery, and then pathology. He had been the first professor of each subject, and it is not surprising that Knox, the tragic anatomist, called him "the old chair-maker." A few years later the chair of midwifery fell vacant. Simpson had set his heart on it, and he was well prepared. Many thought him too young, and on hearing this he determined that he would indeed be young. On an impulse he sat down and signed his application James Young Simpson.

Appointed to the chair by the majority of a single vote, he now entered upon his duties with characteristic energy and enthusiasm. Soon he became recognized as the leading British obstetrician. His classroom attracted many students; his house was filled with those who came for healing and those who came to learn. To all of them he accorded generous hospitality.

### David Waldie

All this time he was pre-occupied with the mystery of pain, for which as yet there was no remedy. When the news of the American discovery reached him, he told his brother that it was "a glorious thought" and that he "could think of naught else." In January, 1847, he was the first to use ether in obstetric practice. But before long it was apparent to Simpson, as to many others, that the ideal anaesthetic had not been found. Ether was slow and uncertain in action, it was often irritating to the air passages, and special apparatus was required for its administration. Something better might be discovered, and Simpson resolved to discover it. His method was the simple one of self-experiment, his assistants also lending their aid as subjects for the trial of various drugs. All Simpson's friends were aware of his quest, and many suggestions were offered. Dr. David Waldie, a Linlithgow lad who had become a chemist in Liverpool, thought that chloroform might be worth trying, and Simpson acknowledged this hint and acted upon it. There is no evidence to prove that Waldie made any experiments on his own account, and certainly he published no results, but he de-

James Young Simpson

serves honour for his suggestion. Another share of the credit is due to Simpson's assistants, Keith and Matthews Duncan. For several months before the discovery the trio used to meet in Simpson's dining-room at 52, Queen Street, after their day's work, in order to inhale, from no apparatus other than simple tumblers, all manner of likely and unlikely vapours. It was a bold venture, and it is not surprising to learn that Simpson's next-door neighbour, Prof. James Miller, would often look in at breakfast-time "just to inquire if everyone was still alive."

### The Experiment

On the evening of Nov. 4, 1847, after several useless efforts, there was produced from a waste-paper basket, so it is said, a little bottle of chloroform which had been prepared by Prof. William Gregory, as Waldie's promised sample had not arrived. It looked heavy and involatile, but Simpson poured a little into his tumbler. He was too well aware of the risks to permit a simultaneous experiment by all three observers. Very soon Keith and Duncan noted the effect on their chief. They too

sniffed the vapour from their tumblers, and soon all were unconscious, Duncan snoring loudly and Keith, having slipped from his chair in the 'stage of excitement, kicking at the table legs. Naturally, Simpson recovered first, fully aware that he had discovered something "far stronger and better than ether." And so indeed it proved. Within a short time chloroform had

"Anaesthesia" at the age of 17. The first child to be born while the mother was under the influence of chloroform administered by Prof. J. Y. Simpson.

displaced ether and had become the anaesthetic of choice all over the world, save perhaps in the northern States of America, the original home of ether.

Of course Simpson never claimed to have discovered chloroform, nor did he claim to be the first to use general anaesthesia. The substance chloroform was first produced about 1831 by Guthrie in America, Soubeiran in France, and Liebig in Germany, each chemist working independently of the others. Since then it had been used as an internal remedy; indeed it is so used to this day.

Simpson was, however, the first to demonstrate the anaesthetic properties of chloroform. Within a week of his discovery, on Nov. 10, he read a paper to the Medico-Chirurgical Society entitled "An Account of a New Anaesthetic Agent as a Substitute for Sulphuric Ether in Surgery and Midwifery." The contribution was printed and published on Nov. 15, by which time Simpson was able to add notes on the employment of chloroform anaesthesia in three cases at the Royal Infirmary. The first patient was a Highland boy who could speak only Gaelic. His name is unfortunately not known to us. From his arm Prof. Miller removed a large sequestrum of the radius, Simpson acting as anaesthetist. It was natural that Simpson should also introduce chloroform into obstetric practice. The first child whose mother enjoyed its beneficent influence was the daughter of a Dr. Carstairs, of Edinburgh, who was duly christened "Anaesthesia." Her career cannot be traced, but a photograph of her at the age of 17 stood on Simpson's desk and he called her his patron saint, "St. Anaesthesia."

### John Snow

It now seemed as though chloroform would fulfil the anaesthetic ideals of efficiency and safety. "Never mind the pulse, but watch the breathing carefully," was the watchword of Simpson and his disciples. Lister wrote a most valuable paper on chloroform anaesthesia, which is still well worth reading, and he stated that Syme had performed five thousand operations under chloroform without a death which might be attributed to the anaesthetic. Lister's paper appeared in 1861. But long before that date a disquieting series of deaths had been reported from various quarters, and the safety of the new anaesthetic had been called in question. Attention was now turned to the need for accurate dosage to replace the somewhat haphazard "rag and bottle" method.

Among those who promoted the safety of chloroform administration by new dosimetric methods was John Snow, who had already won fame by proving that cholera was a water-borne disease. Turning his attention to anaesthetics, and especially to chloroform, he was the first in Britain to limit his practice to anaesthetics, and it was he who administered chloroform to Queen Victoria at the birth of Prince Leopold and subsequently of Princess Beatrice. The name of Snow well deserves to be linked with that of Simpson. Although chloroform lost some of its popularity when its safety was questioned, it retained its place as the principal anaesthetic until the turn of the century. Indeed, the words anaesthesia and chloroform became synonymous, and the verb "to chloroform" was in constant use. As time went on, the use of ether was revived. There was a contest between ether and chloroform; new mixtures, new sequences of other vapours and gases, were used; premedication by various narcotics came into fashion, and anaesthesia gradually became one of the most exact and precise of the medical specialties.

### Simpson the Many-sided

Of the modern position of chloroform in anaesthetic practice I am not qualified to express an expert opinion. No doubt the Centenary Celebration to be held in Edinburgh next week will call forth opinions regarding chloroform as used to-day from expert anaesthetists who can speak with authority. But perhaps one may be allowed to conclude this note by a few further remarks on the discoverer, Sir James Young Simpson, who became the first Scottish medical baronet in 1866, four years before his death. Although chloroform anaesthesia was his greatest achievement, it was by no means his only claim to distinction. He wrote voluminously on homoeopathy, on "hospitalism"—his suggestions have quite a modern flavour—and on many another subject. In his promoter's address at the Edinburgh Graduation Ceremony of

Room at 52, Queen Street, Edinburgh, in which anaesthetic value of chloroform was discovered.

1868, he remarked that "by means of electric lights the human body might one day be rendered transparent. "Thus he prophesied Roentgen's discovery. Simpson's greatest campaign, and one on which he laid much stress, was his advocacy of a means of controlling haemorrhage by means of needles, so as to avoid the silk ligature which promoted and perpetuated sepsis. Acupressure, as he called it, brought him into conflict with surgeons, who resented his encroachment upon their domain. The introduction of the antiseptic method, strangely enough, was opposed by Simpson, who asked Lister to show his "mythical germs." Nevertheless this method led Lister to introduce the catgut ligature. There was then no need for acupressure, and soon it was entirely forgotten. The versatile outlook and abounding energy of Simpson could not be limited by his own specialty of midwifery, although he advanced that science in no small way. Nor did he limit his investigations even to the wider field of medicine and surgery, although he contributed to both.

In some strange fashion, amid the claims of a huge practice and of many medical interests, he found time to establish himself as an authority on archaeology. His essays may still be read with interest—on Scottish charm stones, on medical officers in the Roman Army, on leprosy in Scotland, to mention only three, written with a conviction that reveals his wide and varied store of knowledge.

Simpson believed in living strenuously. But even his happy possession of the ability to fall asleep at any time or in any circumstances did not altogether relieve the heavy strain imposed upon his sturdy frame. He fell a victim to coronary thrombosis, "the doctors' disease," and died in his fifty-ninth year. He earned the gratitude of many a sufferer, and it is fitting that he should be remembered to-day and honoured for all that he did, especially in his great service to the science of anaesthesia one hundred years ago.

## A METHOD OF ABDOMINAL PALPATION

BY

E. W. PRICE, M.B., B.Ch., D.T.M.

*Pinnu Mission Hospital, Belgian Congo*

The conventional method of abdominal palpation, with the patient supine with (or without) the legs drawn up and with (or without) a cushion under the shoulders, though generally sufficient, is sometimes difficult on account of the tonicity of the abdominal muscles, the amount of fatty tissue, or the inability of some patients fully to relax the abdominal wall. This inability may be the result of nervousness or misunderstanding, or even a desire to be helpful. Moreover, the placing of the hand beneath the lumbar region for palpation of the kidney often causes the patient to lift himself in a desire to help, though actually it makes palpation more difficult.

In tropical practice, where patients are more numerous, the time taken in explaining to an uneducated native that he must lie on the couch, on his back, and not keep lifting his head to see what is being done, is another disadvantage; besides which, a chair or table is not always available in itinerant practice, and the native bed is too low for convenience. The alternative—of laying patients on the ground—is tiring if there are many to examine.

Such considerations led to a search for a method which would assure complete relaxation of the abdominal wall, which would dispose of the need for a table or chair, and which would avoid the time spent in placing the patient suitably on a table for examination. The thick fatty abdominal wall common in European practice is relatively uncommon in Africa. The method to be described was suggested first by remarking the ease with which one can examine the spleen of a child if he is made to bend forward and hang the head down. Nicholson's method (of restraining thoracic respiration with one hand) has the disadvantage of maintaining one hand in a state of muscular tension while trying to palpate with the other. Marshall (1933) described a "dangle" method similar to that of the palpation of the spleen referred to, but with the patient seated and the surgeon standing behind.

The following method is recommended because of the complete relaxation afforded, the fact that neither chair nor table is essential, though a chair is useful, and because an uncooperative patient, breathing normally, cannot contract his abdominal muscles in this position and thus frustrate the examination.

## Details of Procedure

The examiner stands on the patient's right, and instructs him to bend forward with his arms and head dangling down. The patient may be standing or sitting. The examining hand (the right) is passed between the hanging right arm of the patient and his abdominal wall, then right across the abdomen until the left anterior superior iliac spine is felt. It is much easier in palpating to pull the hand back than push it forward. The left hand is placed on the patient's back opposite the palpating hand and its position changed with that of the latter. This hand serves to steady the patient and also to act as counter-palpation to the hand on the abdominal wall.

The routine examination is as follows: Starting at the left anterior superior iliac spine, the hand is drawn inwards and upwards along the iliac fossa to palpate the iliac colon and iliac glands. The ureter is sought (and is often palpable in thin patients) at the pelvic brim (Tournoux's point). Returning then to the iliac colon, its course is followed upwards to the subcostal region. The left hand then pushes forward in the left costo-vertebral angle to facilitate palpation of a kidney. One then feels for the spleen. Crossing the upper abdomen, the right lobe of the liver is palpated beneath the costal margin, and often one can flip it across the fingers and so estimate its consistency, size, and surface. This examination is made easier if the fingers are hooked under the costal margin. The region of the gall-bladder is also palpated. The left hand, which has followed the right across to the patient's right, now presses forward with a view to palpation of a kidney, and the right colon is then followed down to the caecum, and the right ureter is also sought. Finally the examining hand is replaced across the lower abdomen and the suprapubic and the inguinal regions palpated. In a lax abdomen with thin walls it is often possible to pass the fingers into the pelvis from above, giving the sensation of putting the hand into a basin covered with a blanket. If necessary, the examination can be completed with a bimanual examination of the prostate.

## Comment

The advantage of this method, apart from those stated above, is that the whole abdominal palpation is bimanual, allowing thus for a more definite impression of the consistency and extent of any palpable structure. The simple downward palpation of the conventional method fails somewhat to assure this, in that the counter-pressure is made by the inert couch.

## DEAF-MUTISM IN SWITZERLAND

Prof. Ernst Hanhart, of the University of Zurich, who has been working for many years on problems of genetics in certain selected Swiss populations, paid his first visit to England on Oct. 7 to deliver the Galton lecture—the first for eight years—at University College, London. His subject was human genetics, with special reference to deaf-mutism and other abnormalities.

In Switzerland the average number of deaf-mutes has been given as 24 per 10,000 population, as compared with only 8 per 10,000 in Europe as a whole. Prof. Hanhart said that Switzerland was an excellent theatre for genetic study because of the many villages which had been virtually isolated for centuries. He had a number of family histories going back to 1600, and the standard of observation by general practitioners and hospitals was so high that few important cases of variation were missed. Even now, in a time of change, very few movements of population disturbed these quiet valleys, and complete family pedigrees could be collected without much difficulty. In almost every region of Switzerland records of family histories were available, and fortunately there was very little venereal disease to complicate the picture. The frequency of pathological mutations was relatively high among these isolated communities, where the marriage of cousins and incestuous unions were not infrequent. At the same time there were isolated communities which showed almost no pathological mutations.

Prof. Hanhart's lecture was illustrated by some elaborate diagrams showing pedigrees in which cases of deaf-mutism and of diabetes mellitus occurred sporadically. His investigations had extended over twenty-five years, and he had endeavoured to consider not one character or condition alone but all the accompanying constitutional features. In one village with 2,400 inhabitants near the eastern end of the Lake of Geneva there were 49 deaf-mutes. Deaf-mutism might appear in an ancestor and not be repeated for two successive generations, then reappearing. In one instance a man in this region married a woman

from another region, so that no question of consanguinity arose, but the woman had two deaf-mute sisters, and the children of this marriage, nine in number, included three deaf-mutes. A man not a deaf-mute, but with deaf-mutism in his ancestry, married twice and by each marriage had deaf-mute children. Another example of these strange and wayward manifestations was of twins, a deaf-mute boy and girl with normal hearing. The reputed father was a deaf-mute, but on further inquiry, including blood tests, it was eventually shown that the twins were born of an incestuous union between the mother and her own father.

Although it was to be expected that when two deaf-mutes married all their children would be deaf-mutes, this did not always occur. He had one case where the child of such a union, born a deaf-mute, was able later to hear and to speak. He declared himself strongly against the sterilization of deaf-mutes. Deaf-mutism was sometimes seen in association with cretinism, but cretinism was produced by other factors and had now largely disappeared from Switzerland as a result of the much better feeding of the people. He protested against the idea that deaf-mutism necessarily went with feeble-mindedness. The greater number of these deaf-mutes were intelligent and conscientious workers, not to be distinguished, except by their deaf-mutism, from the general group. Prof. Hanhart also showed the family histories of nearly one hundred cases of diabetes mellitus. A number of families, he said, carried two mutations—deaf-mutism and some derangement of metabolism.

### NEW CONTINENTAL HOSPITALS

A delegation from Charing Cross Hospital was sent recently by King Edward's Hospital Fund for London to study methods of hospital design and planning in Europe. It consisted of three members of the medical staff (Mr. Norman Lake, Dr. H. W. Vines, and Dr. Doyné Bell) and one experienced hospital lay administrator (Sir John Stewart-Wallace). Five hospitals were visited, namely, the Bürgerspital at Basle, completed in 1945, which was the subject of an illustrated article in this *Journal* (Oct. 5, 1946, p. 500), where it was described as a landmark in municipal hospital building; the Polyclinic at Zurich, also completed in 1945, together with the special hospital for children in the same city; the Beaujon Hospital at Clichy, Paris, completed in 1935, and the new Southern Hospital at Stockholm, completed in 1944. All these hospitals are owned and controlled by the city, or in Switzerland by the canton, not by the State.

In a long report to the committee of the Fund the delegates begin by pointing out that hitherto the planning of a hospital has been left largely to the architect, but, inasmuch as the hospital is an apparatus to be worked by doctors for the benefit of patients, both doctors and patients ought to be invited to share in the planning from its earliest stages. One of the striking features which impressed them on their tour was the extent to which on the Continent the experimental approach towards reconciliation of conflicting claims and the maintenance of a balance between various interests has replaced tradition in the solution of problems of hospital organization. For example, at Stockholm even the walls have been shifted to try out various patterns of floor spacing, and at Zurich a hut was attached to the old hospital building with all the services laid on, and here patients were admitted over a period of two or three years. The advantages and shortcomings of the different arrangements were discussed at periodical meetings of the planning committee, and the final decisions were made accordingly.

#### Variations in Planning

The Beaujon Hospital, Paris, is a vertical building of fourteen floors—an exaggerated reaction from the pavilion type. Unfortunately, although the hospital is built vertically, the departments are planned laterally in the attempt to make each floor an independent unit. The new Polyclinic at Zurich is part of an extensive rebuilding plan of the Zurich Hospital Centre, and is partly under the control of the cantonal health department as a public hospital and partly under the education department as a university school. The new hospital at Basle contains some 700 beds for general surgery and medicine, with an isolation block for infectious diseases and tuberculosis. The

Stockholm hospital is a massive building with the flat, unrelieved surfaces which are a characteristic of Swedish domestic architecture. When completed it will take 1,200 patients.

The form of these large hospitals seems to be fairly standardized on the principle of two separate blocks, one for in-patients and the other for out-patient services, the two being connected by transverse corridors. The central administration rooms are sited in the main hospital building, not in a separate block. In all except the Paris hospital there are private beds for the use of honorary members of the staff. At Basle there are 3 private beds of the first class for which patients pay full private fees, and 70 of the second class for which reduced fees are paid. At Stockholm there are 93 private beds; an average of five or six for each department head. The methods of internal administration differ. At Basle there is a hospital committee of management appointed jointly by the canton and the town and containing two medical members, with an advisory committee consisting of the heads of the departments. There is a lay director at Zurich and a medical superintendent at Stockholm; at Paris the visitors failed to discover whether the head of the hospital was medical or lay.

All the hospitals are planned on the basis of the clinic as a unit, with a professor or someone of similar standing at its head. The position carries with it at most of the hospitals the right to practise privately. In Sweden and Switzerland the heads of departments are provided with good suites of rooms including rooms for consultation and examination. At Basle they are paid about £45 a month for their hospital work, and also receive private fees and a capitation fee of about 6s. an hour for each student. Swiss professors have a number of official assistants who, at Basle, are paid about £600 a year and below them are house officers whose salary is £420. In Paris there is a special building of flats for married medical and technical staff; the building is said to house 40 families. Shortage of nurses and domestic staff seems to exist everywhere.

#### European Hospitals and Medical Teaching

None of the hospitals mentioned is a full teaching school in the British sense; students attend only for clinical instruction. In Paris the unqualified students seem to be used freely in positions of some responsibility. A department may be staffed by the senior chief of the service, with, under him, a house officer who is often not fully qualified, and with four student externs. If the students wish to do so they can become externs after one year's clinical training, and remain as such for four years. Then they can become interns for four years more. In Sweden the medical course extends for eight years: three years' pre-medical and pre-clinical and five years' clinic work.

The report contains a vast amount of useful detail on such matters as ambulance unloading arrangements, night service, mobile bed equipment, nursing organization, preparation of service of meals, and siting of kitchens. The two-bed room met with fairly frequently—an arrangement which was popular at the new Queen Elizabeth Hospital, Birmingham. The delegates suggest that a 25-bed unit might be most probably arranged by having two rooms each of eight beds, one room of four beds, and five single rooms. At Stockholm the units, each of 16 beds, are looked after by one assistant doctor. Three of these double units, with a few private beds, make a medical clinic, and four a surgical clinic. In the operating units nothing outstandingly new was found. In all cases the unit was planned about a central corridor with the anaesthetic room on the opposite side. At Stockholm there are 28 theatres.

The delegates crystallize their impressions in some final conclusions. We quote a few:

Beauty in every aspect of hospital life is of first importance, not only in the external aspect of the buildings and in their harmony with their surroundings, but in the size, proportions, light, and decoration of the interior. There should be a high measure of flexibility in all arrangements for the nursing and other staff. There should be opportunity to live in or out for trained nurses. The most suitable unit of beds forming a ward under the charge of a single sister seems to be 24 or 25. Within the unit the largest bedroom should contain not more than eight and not fewer than six beds.

It is probably desirable that the out-patient department should be physically separate from the in-patient block. The maternity department, as regards both in-patients and out-patients, should also be physically separated from the departments dealing with general

ckness. The comfort of the out-patients should be carefully studied by the provision of chairs and tables instead of benches in waiting-alls, and reasonable provision of canteen facilities at certain points. Air-conditioning is essential for operating theatres and x-ray rooms, but not necessarily for the general hospital. The installation of automatic transmission should be carefully considered as a means of saving manpower.

It is to be hoped that the report will be studied by those responsible for hospital administration and planning in Britain, where it may well affect future policy.

## Preparations and Appliances

### CONTROL OF HOT-AIR STERILIZATION OF SYRINGES

Drs. J. COLQUHOUN and ARTHUR JORDAN, of the Royal Sheffield Infirmary and Hospital, write: We have been developing the use of all-glass syringes sterilized by exposure to a temperature of 160° C. for one hour. Experience showed the need for check on both time and temperature, since apparatus was not entirely satisfactory and personnel were largely unskilled. We were familiar with the use of control tubes which changed colour when autoclaving was adequate, and we approached the makers for something similar, to change colour at a temperature of 160° C. after one hour. They were able to produce such a tube, and in use it has proved satisfactory. The control tube is placed in the barrel of a syringe enclosed in a glass tube as are the other syringes; thus penetration of the heat to the inside of the items to be sterilized is verified.

These tubes led us to detect that the temperature on different shelves of a hot-air oven could differ: with a thermometer we found differences of up to 15° C. In the light of this finding we feel that sterilization for one hour in a hot-air oven with a single thermometer which reads 160° C. or more the whole time is not necessarily adequate sterilization, and more control is needed.

The control tubes are made by Messrs. A. Browne and Co., Chancery Street, Leicester.

## Reports of Societies

### THE RENAL CIRCULATION

A meeting of the Section of Experimental Medicine of the Royal Society of Medicine was held on Oct. 21 for a discussion on the renal circulation.

#### Radiographic Interpretations

Dr. A. E. BARCLAY introduced the subject by describing investigations which had been undertaken at the Nuffield Institute for Medical Research, Oxford. The growth of the clinical use of radiology, he said, had been phenomenal, not only in volume but in value, yet radiology had been frequently ignored as a means of approach to experimental studies. One of the great virtues of radiology was the opportunity which it offered of studying function without operative interference. It was necessary only to mention in this connexion the gastro-intestinal tract, the gall-bladder, and the kidney. Again, in studying just excretion from the lung it was possible by using radio-opaque dusts to see the distribution in the lung field of the living animal. The study of renal circulation had also benefited greatly from radiological investigation.

In the work on the renal circulation Dr. Trueta and Dr. Barnes, who came to the Nuffield Institute in 1941, had made a special study of renal ischaemia and the crush syndrome. A simple technique was developed by which, with the assistance of a radio-opaque substance, radiographs were taken at stated intervals of the lower abdominal aorta. In September, 1945, a team was formed to investigate the changes which occurred in the kidney in the crush syndrome—a study which was accelerated when presently adequate supplies of thorotrast

became available. This substance proved satisfactory and had no effect on the blood pressure. The method of cine-radiography was at first employed, but this was expensive, and the actual picture was too limited in size to be very useful. Cine-radiography had now been superseded by large still films (38×15 cm.) which included the whole abdomen. Rabbits were used in the experiments. As soon as the animal was anaesthetized a series of films was taken at intervals of 3 or 6 seconds, so as to get the control picture, and then a tourniquet was applied or other procedure adopted and a further series of films was taken at the same intervals. Comparison of the two series showed that the procedure caused large changes in many of the vessels, including the renal artery and renal vein.

The most constant observation was that with the tourniquet the renal artery was diminished in diameter and the renal vein greatly increased. The tourniquet technique was tedious, and experiments were made to find out whether electrical stimulation to the proximal end of the cut nerve could be used instead, and this was found to be effective. Prolonged anaesthesia by itself did not appreciably affect the measurements of the vessels. Various drugs were also tried without any significant effect. Severe haemorrhage reduced the size of both the renal artery and vein. It was suspected that the changes found in the tourniquet experiment were due to a nervous action, and this was confirmed by further investigation. The blood was shown not to be taking its normal course but to be short-circuited in some way.

#### Characteristics of Blood Flow

Dr. J. TRUETA followed with a pictorial description, accompanied by many lantern slides, of the renal circulation. He said that this work had occupied a little more than three years. To begin with, it was suspected that the effect produced on the renal vessels by a tourniquet could be reproduced by electrical stimulation of the splanchnic nerve. Experiments were carried out on rabbits in which the nerve was sectioned and stimulation was applied by means of faradic current. Methylene blue was then injected into the renal artery and was shown to distribute itself in a strange pattern which had not been observed before. They had had a suspicion of some anastomosis or short-circuiting occurring in the kidney, but they had not known which were the vessels concerned or their calibre or arrangement. Dr. Trueta drew attention to the arrangement and structure of the glomerular vessels as shown by means of thorotrast and other opaque media. The filling of the vasa recta in the rabbit was also shown. Another example was the cortical ischaemia produced by injection of staphylococcus toxin. The short-circuiting mechanism had been repeated in the cat and other animals. He mentioned that more than 700 radiographs had been studied in the course of this work and the movements observed had been analysed. In one example a tourniquet was placed around the thigh of the animal and an injection given, with the result that there was a great concentration of the contrast medium in the cortex, with complete emptiness of the medulla; but it had been shown to be possible to prevent the action of the tourniquet by splanchnic section, and after an interval the cortical circulation was seen to be closing and the medullary circulation opening.

This work was still being pursued, and a new x-ray procedure was being employed with a special technique as a result of which the glomeruli could be seen in great detail. He showed a remarkable series of x-ray pictures illustrating the stages and vagaries of renal circulation, the cortical ischaemia following the application of the tourniquet, and the different result when the tourniquet was applied after splanchnic section. He also showed "neoprene" casts illustrating true juxta-medullary arterial degeneration, and radiomicrographs of the cortex and capillaries.

Dr. J. F. HEGGIE showed some illustrations complementary to those already shown by Dr. Barclay and Dr. Trueta concerned with the experimental production of cortical necrosis in the rabbit, with special reference to glomerular circulation. He said that when the right renal blood flow was measured directly in the normal anaesthetized animal by the method of Dunn, Kay, and Sheehan the rate was found to lie between 2 and 4 ml. per gramme of kidney substance per minute, usually

between 2.5 and 3 ml. When finely particulate carbon-suspended in serum was injected into the renal artery in the normal anaesthetized animal at the same rate as the blood flow therein for 3 seconds and the pedicle immediately clipped, the renal vascular architecture was clearly demonstrated, and the pigment was found in the intra-interlobular arteries and afferent glomerular arterioles and glomeruli, and the essentially glomerular character of the circulation was confirmed. The efferent vessels of the glomeruli situated near the medulla, to which in 1941 the speaker gave the name juxta-medullary glomeruli, provided the supply to the medulla, and this, he suggested to Drs. Barclay and Trueta, was the explanation of the short-circuit which they described in their preliminary report. These vessels were wide and ran a fair length before they broke up to form the very rich capillary network around the tubules of the medulla, the ellipse of Henle, and the collecting tubules.

It was found that the glomerular volume in the normal rabbit changed five times each second. These velocities were not altogether unexpected having regard to the fact that the glomerular capillaries were interposed between two arterioles in which the pressure was high. In less "acute" experiments, if the total renal minute volume remained the same and if the medullary pathway alone was operating, then the glomerular volume was changed 30 times each second and the velocity proportionately increased; but if the juxta-medullary glomerular capillaries were dilated (and they could accommodate the normal glomerular capillary volume) the rate of change was five times per second and the velocity in the dilated capillaries was still normally 1.25 mm. per second.

Dr. E. M. DARMADY said that cortical necrosis following severe accident was not a very common finding. There were certain features found histologically in such cases which did not fit in very well with the findings shown that evening. The bloodless glomeruli, the puncture of the vein at the glomerular area, and the congestion of the parts in the medullary zone were among these. He felt that it was not quite fair to compare the findings in the rabbit with the human at this stage, because one knew that experimentally it was very easy to induce an ischaemia by traction on the kidney. They should be guarded before arguing from the rabbit to man.

Dr. R. H. PARAMORE said that he had made attempts to explain the lesion in the cortex in eclampsia and in certain cases of pregnancy after, for example, accidental haemorrhage (though only in concealed accidental haemorrhage, not when blood escaped), and in such cases it seemed to him that the kidney was compressed and that the urine secreted could not get out. There was blood stoppage through a part of the kidney and the pressure of the kidney was increased. It seemed to him that mechanical factors were extremely important.

The President of the Section said that he had been studying the circulation in the liver by means of the injection technique, and he had seen some phenomena which were very similar to those described in the case of the kidney. The thing which impressed him also was the mechanical factor, the swelling of the liver parenchyma, which dammed the blood back into the portal circulation.

The 291st annual Harveian Oration was delivered on St. Luke's Day, Oct. 18, at the Royal College of Physicians, by Dr. C. E. Lakin, Consulting Physician to the Middlesex Hospital, who chose as his subject "Our Founders and Benefactors." He said that the College was a Royal Foundation, having been founded in 1518 by Henry VIII at the instigation of one of his physicians, Thomas Linacre. Linacre was one of a group of men, including Grocyn, Dean Colet, Sir Thomas More, and Erasmus, who were profoundly influenced by the Renaissance of Learning and who took an active part in it. The foundation of the College and the revived interest in medicine were the direct result of that remarkable mental awakening. Among the Benefactors mentioned were John Caius and Dr. William Gilbert. He pointed out the three stages in the evolution of knowledge as exemplified by these investigators. Linacre looked to the past and recaptured the knowledge of Aristotle and the old philosophers; Caius was deeply steeped in the same learning but turned to the practical investigation of nature; while William Gilbert steadfastly looked forward, and by introducing the experimental method into research may be said to be the first English modern scientist.

## Correspondence

### Soviet Science

SIR,—Your leading article on "Genetics and Science in the U.S.S.R." (Oct. 18, p. 616) will not fail to stir the emotions of its readers; it also stirs reflection. What is happening in the Soviet Union is no haphazard attempt at security but a deliberate policy based upon a historical theory, a theory concerning the evolution, advance, and prosperity of a nation or of a group of any "beings." The theory may be shortly stated one which ascribes all these possibilities to war between opposites. War within, war without, are the productive habits productive in a nation of these events.

This theory is in flat contradiction to the facts that are the files of that study of relations which we call science, a most clearly in the part of this study which gives a historical account of the relations within and without living organisms. The relations to which biological science ascribes what equilibrium and evolution have been exemplified by organisms (a nation is an organism in potential equilibrium) may generally stated as the union or mutual balancing of complementaries. There is pressing need to-day not for a new philosophy but for a plain declaration by science of this general induction from its studies, and an exposure of the falsehood and fallacy from which the policy described in your article derived.—I am, etc.,

Wantage.

K. W. MONSARRAT.

### Education for General Practice

SIR,—At the beginning of the article by Dr. John Rickm on "Psychology in Medical Education" (Sept. 6, p. 363) tribute is paid to the teaching which many young doctors get from their principals in private practice; but the writer does not on to include the general practitioner in his scheme of teaching for the student. It would be so easy to arrange—a panel teacher-practitioners chosen by their fellows, and students giving two nights a week in their final year to sitting in at surgery, helping with medicines, and going out to lactic case with the doctor. Most students would think it fun and be grateful for it and learn a great deal, and the older men would long last get some recognition from their own profession for the good work they do.

The general practitioner is a lonely man. He is too busy to meet his fellows, and in a poor district of London, say, perhaps the only chance of understanding from his fellows and chance to talk about his cases is with the medical officers of the local L.C.C. hospital. They probably never meet, but they do talk on the telephone. The average H.S. or H.P. of a teaching hospital is so afraid of being "snagged" and is therefore a cocky, and in any case changes so often, that the general practitioner gives up quickly all hope of any fruitful medical contacts with even his own hospital.

As this letter shows, I seem more interested in the general practitioner than in the student, but they cannot be separated. The student can teach the doctor the latest in medicine. At present has to rely on the drug-house man (who often does this very well) I have the liveliest memories of pleasure in being taught by principals and teaching them too, and later on when I had assistant myself. I would hold that the house job and the assistantship in general practice are equally necessary and honourable to anyone starting a medical career. This, I feel, should be officially recognized with honours of some kind for the teacher-practitioner (honorarium or title).

So much has been taken away from the general practitioner (and the patient)—the satisfaction of fee-giving and taking (still recognized by the patient, who feels that the private doctor's medicine must be better than the panel-doctor's), the pride in the practice which inherited from a good man and which he could only dispose of to a successor tried and approved of by him and his patients, the teaching he used to do, the sense of undivided allegiance to his patients, the loss of dignity associated with form-filling, with tuberculous officers who treat your patients without by-your-leave, Ministry of Health doctors who examine your panel records (I know of a panel doctor who does not stay out all day the Ministry doctor comes and does not grind his teeth with rage for days after), Ministry referees who discount your certificates and continually remind you that you serve two masters.

## SURGICAL SUTURES

For ~~the~~ we recommend  
the surgeon's nylon knot.

P.N.33.

### The time, the place —and the Portanaest

It means much to the General Practitioner to know that the Portanaest is always at hand, equally ready for midwifery in the home and minor surgery in the consulting room or factory. Completely portable, it is very compact yet leaves nothing to be desired in the completeness of its equipment or the easy facility of its use. A master knob controls the rate of flow and pressure; another controls the mixture which can be read from the dial at a glance. For dentistry, the Portanaest can best be described as a portable "Walton"—an indispensable part of a visiting practitioner's equipment. A demonstration will be gladly arranged; literature is available on request.

In comparison with the population as a whole, the professional classes seem especially prone to Diabetes Mellitus.

In the treatment of Diabetes Mellitus, the use of Insulin is now universal. Insulin-Boots is prepared from pure crystalline Insulin and tested in accordance with the regulations made under the Therapeutic Substances Act, 1925.

Supplied in rubber-capped vials as below:

20 units per c.c. Vials of 5, 10 and 25 c.c.  
40 units per c.c. Vials of 5 and 10 c.c.  
80 units per c.c. Vials of 5 and 10 c.c.

## INSULIN-BOOTS

Further information concerning Insulin-Boots gladly sent on request to Medical Department, BOOTS PURE DRUG COMPANY LIMITED, NOTTINGHAM D-1

## After Debilitating Illness

Allenburys Beef Juice is particularly suitable for administration in convalescence after severe and debilitating illnesses. It is not merely a stimulant but contains, in palatable and concentrated form, the nutritious and stimulant constituents of fresh, raw, beef juice, including albumen which is conserved by the process of manufacture *in vacuo* at a low temperature: Allenburys Beef Juice provides an easily administered, highly beneficial supplement to the diet.

In bottles at 3/- and 5/8 each.

for B<sub>2</sub> vitamins

**MARMITE**

yeast extract

Among the nutrients known to be essential for the maintenance of health—mental as well as physical—are the vitamins of the B<sub>2</sub> group. Marmite contains riboflavin (1.5 mg. per oz.) and niacin (16.5 mg. per oz.) and also the less well-known B<sub>2</sub> factors such as pyridoxin, pantothenic acid, choline, biotin and folic acid, combined together in a palatable extract.

Present conditions are causing the medical profession to pay considerable attention to food in preventive and curative medicine. Marmite is therefore being prescribed increasingly for private and hospital patients and, as vitamin supplements are specially indicated for mothers and children, it is ordered widely in welfare centres, schools and nurseries.

Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9

Special terms for packs for hospitals, welfare centres and schools

Obtainable from Chemists and Grocers

Large-scale diphtheria immunization is telling its own success story . . . as the development by Glaxo Laboratories of an efficient whooping cough vaccine brings nearer the promise of a similar trend in the statistical picture of pertussis. For the convenience of simultaneous prophylaxis against both diseases, the pertussis vaccine and diphtheria toxoid are combined as one immunologic weapon. Each cc. of the 'Combined Prophylactic Glaxo' contains at least 25 diphtheria prophylactic A.P.T. and 20,000 million H pertussis (alum-precipitated). The course for primary immunization is three injections—0.5 cc, 0.5 cc., and 1.0 cc. at monthly intervals—a feature of clear advantage to those combating these diseases.

### DIPHTHERIA-PERTUSSIS COMBINED PROPHYLACTIC Glaxo

Diphtheria Prophylactic A.P.T. plus Pertussis Vaccine (Alum-precipitated)

In 5 cc. and 10 cc. bottles.

I am not a die-hard, but I am sure that the satisfactions in a general practitioner's life are now very much less than they used to be and the dissatisfactions more. After all, what is the use of educating people to be doctors if being a doctor is no fun? If nothing could be brought back to general practice it would be more fun.

Dr. Rickman suggests that anatomy should go on side by side with work in casualty. I entirely disagree with this. A student doing his anatomy and physiology has quite enough to deal with motionally. It is his "latency period," as it were, as a student. Let him learn to deal with the body, dead, get to know it and be afraid of it, and enjoy the nice machines of physiology first. The denying of affect common to the life of the dissecting-room (if the proposal were followed) might lead to a greater carrying over of this mental attitude into relations with patients; or alternatively some of the students would never learn their anatomy.

The student nursing orderly is a first-rate idea. This, I think, could go well with the anatomy-room time or even earlier if the student is doing his First M.B. at hospital. (Why should he not earn his keep part of the time in this way?) It would give him a more limited responsibility and give chances for the expression and learning of gentleness (the student when he is in casualty is already a doctor, diagnosing and prescribing treatment). In the wards he would help to lift the heavy patients, make beds or learn to fix pillows (in general practice this was the most valuable single bit of knowledge that I had). I truly believe he would be willing to sweep floors and empty cans! I wish it could come true. Lastly, that footnote on the quack is a masterpiece. But should it not be admitted that the quack may be sometimes more imaginative than his contemporaries?—I am, etc.,

London, N.W.1.

JAMES M. TAYLOR.

### Penicillin for Infected Hands

SIR.—Frank D'Abreu *et al.* in their article on penicillin and the treatment of infected hands (Oct. 18, p. 603) proved one general rule—that if patients with septic hands are given penicillin in twice-daily doses of 300,000 units, in addition to other methods, then the loss of duty would be shorter than if penicillin had not been given; but one is not justified in giving all cases of sepsis of the hand routine systemic penicillin. Even in these days of adequate supply one still ought to economize in its use; therefore one has to ascertain in which cases penicillin will have most value.

Before deciding on any treatment the following factors should be ascertained: (i) Degree of pain (number of nights patient has been kept awake); (ii) degree of tenderness; (iii) temperature; (iv) presence of lymphangitis or adenitis.

During the first six months of this year I was in charge of a busy casualty department and had occasion to treat some 600 septic fingers. During this time I tried, with varying degrees of success, all the recognized methods of treatment with a view to assessing their value. I came to the following conclusions: (a) In very early cases, if the patient has pain not sufficient to keep him awake at night, prophylactic penicillin would be sufficient alone in some cases and incision avoided. This was shown, for instance, in the nurse (Case 8 in the article) who received by mistake some 500,000 units. (b) Once, however, a patient has lost a night's sleep due to pain, or there is no alleviation of the pain despite 24 hours' penicillin therapy, immediate incision is always indicated. (c) The presence of pyrexia above 99.4° F. (37.4° C.) with or without lymphangitis and adenitis, calls for penicillin.

I also tried the effects of penicillin in those rare cases of bone necrosis. These are the cases that, despite the above measures, do not respond. They are: (i) The neglected cases which come up for treatment only after almost all the pulp space has been destroyed; (ii) the rare case which, despite incision and penicillin therapy, fails to resolve. I have, during the six months under review, seen thirteen such cases. One begins to suspect that progress is not being made when, despite lack of pain and other symptoms, the finger begins to discharge pus profusely day after day. Radiological examination at this stage invariably shows some degree of bone rarefaction. Systemic penicillin alone to these cases does not seem to alter to any extent the amount of discharge once the bone is involved. This is due to the following reasons: (i) Bone necrosis is due to tension in the pulp space occluding the nutrient artery;

the blood supply to the bone is diminished, and the infection early takes a hold and the penicillin, therefore, given systemically cannot reach the area; (ii) the probable walling off of the necrosed area. Systemic penicillin was actually tried in the first three cases and had to be discontinued and local penicillin therapy instituted.

Of these thirteen cases all but two responded well to local penicillin infiltrated down the sinus and around the necrosed area. The two that did not respond to treatment showed, on radiological examination, that some two-thirds of the terminal phalanx had been destroyed. Both these cases, however, continued to discharge pus after the usual operative interference, but after local penicillin had been infiltrated the wounds healed rapidly.

The method I used was as follows. The discharging sinus was cleaned out and dried as much as possible. About 0.25 ml. containing about 50,000 units of penicillin was injected through a wide-bore needle which passed through the sinus into the necrosed area of bone. A dry dressing was placed over the affected area. The dressing was undisturbed for two days. After removing the dressings, in many cases they were found to be clean and uncontaminated by pus. From then onwards the sinus seemed to heal very slowly but without further discharge. In the minority of cases after two days there was still a discharge, but not very profuse, and the infiltration was repeated. In two cases three attempts were made before the discharge finally ceased permanently.—I am, etc.,

Manchester.

E. JAFFE.

SIR.—The excellent article on systemic penicillin in septic hands (Oct. 18, p. 603) brings me to mention a new method of local application. It is effective and economical. Penicillin powder or solution when applied to an incision in a septic hand is rapidly washed away by outflowing blood and pus, but a small tablet can be placed in the small abscess cavity of, for example, a pulp infection and will remain there long enough for blood to clot around it. One firm makes up these tablets, 10,000 units to a tablet, actually for solution.

The advantages of effective local application of penicillin over systemic are obvious. 10,000 units inside an abscess cavity wall must be worth 100,000 units outside in the blood stream. The incision and abscess heal so rapidly that smaller incisions can be made and drains dispensed with in many cases. Of course the method can only be used after surgical intervention has occurred, which ideally should be unnecessary but in practice is necessary in the majority of infected hands.

I thoroughly agree with leaving the initial dressing for three days, although the patient should attend during this time for temperature recording, etc.—I am, etc.,

London, W.13.

JOHN P. RAW.

### The Harveian Orations

SIR.—In an interesting article on the Harveian Orations (Oct. 18, p. 622) by Messrs. W. J. Bishop and F. N. L. Poynter, the following passage occurs: "The oration has been delivered by some 'so obscure as to make their appointment to that post their only claim to fame, and by men of such reputation as to make it their smallest title to distinction.'" The quotation given between inverted commas is theirs, but they do not state whence it comes. The authors go on to say: "The names of Akenside, Arbuthnot, Garth, Mead, Heberden, and Baillie are known to all; but who has heard of John Hawys, Charles Bale, Robert Hopwood, and Charles Feake?"

I wonder whether this is fair criticism. To take the first mentioned, John Hawys (or Hawes), born circa 1660, he matriculated 1676; Corpus Christi, Cambridge; took his B.A. in 1677, M.A. in 1681, M.D. in 1688, and was admitted a Fellow of the Royal College of Physicians on Dec. 22, 1692. He was Censor in 1704, 1725, 1728, and 1732; he gave the Harveian Oration in 1721, and was Councillor 1732–34. This is surely not an undistinguished career? John Hawys was the son of John Hawys (and Maud Gleame), of Wymondham, Norfolk, a physician and theologian who took his M.D. from Corpus Christi in 1660 and died on Aug. 19, 1683. His grandfather, also John, after taking his M.D. from the same college in 1629 practised and died at Wymondham on Dec. 15, 1679. His great-grandfather, again John, was born at Walsham in 1568.

matriculated 1585, was admitted to Caius College, and died in 1663. Dr. John Hawes, F.R.C.P., came to London; he married in 1692 Margaret, the daughter of Dr. William Smith, of Chiswick, and the baptisms of his children are entered in the parish register of St. Helens, Bishopsgate, where he was churchwarden in 1701.

Among his children were William, born Aug. 30, 1704, ordained (Lincoln) 1728; and John, baptized March 12, 1706. Dr. John Hawes was buried May 24, 1736, "at the lower end of the church," his wife Dec. 11, 1741. At some time he may have lived in the parish of St. Albans, Wood Street, and later in St. Bartholomew's Close. John Hawes may be but an obscure name to writers of to-day, but these few notes suggest, I think, that he may have been a worthy and honourable physician.—I am, etc.,

London, W.1.

HUGH S. STANNUS.

### Miliary Appearances in the Lungs in Mitral Stenosis

SIR.—I was glad to see that my article on "Miliary Appearances in the Lungs in Mitral Stenosis" (Sept. 27, p. 488) had evoked some comment, and am particularly interested to learn that Dr. Haldane G. Nelson has seen three such cases within the last twelve months or so. Two of his cases were seen shortly before death from congestive heart failure and might well have shown radiological signs representing a combination of miliary stippling and congestive shadowing. I would be most interested to see the films. The third case he describes is even more interesting, though in a clearly different category, as it was associated with a pyrexia which responded to salicylate therapy. This must almost certainly have been a case of rheumatic lung (rheumatic pneumonitis), first described, I believe, by A. E. Naish. I have seen a peculiar coarse lung mottling in this condition, but a fine stippling of the miliary type has been described by Pendergrass and Leopold (*J. Amer. med. Ass.*, 1945, 127, 701).

I do not agree with Dr. Muriel O'Doherty's views. She describes the pathogenesis of the miliary stippling we see in the finer pneumoconioses, such as the siderosis she quotes of the West Cumberland haematite workers. Haemosiderosis is an endogenous condition. My belief is that the haemosiderin-laden histiocytes are prevented from progressing along the lymph channels to the interlobular collections of lymphatic tissue, either by disturbed pressure relationships in the lymphatics due to chronic pulmonary venous congestion, or, as Prof. A. C. Lendrum suggests in a letter I have recently received from him, by the occurrence of fibrosis in the immediate neighbourhood of the choked-up alveoli. The rosette-like appearances of the individual nodules I described in the magnified photograph should, according to Dr. O'Doherty's theory, have a radio-opaque centre if these are due to hyaline degeneration in the centre of a fibrous nodule. Actually the reverse is the case, as the centre consists of a cross-section of a terminal respiratory bronchiolus, which is, of course, translucent. The finding of abundant haemosiderin-laden cells in the sputum also strongly supports the intra-acinar theory. Like Dr. O'Doherty, I would not expect an x-ray photograph taken to-day to be materially different from the one seen in 1946, but my reasons for doing so would be different from hers.—I am, etc.,

Sheffield.

T. E. GUMPERT.

### Treatment of Varicose Veins

SIR.—We surgeons rise like goldfish at feeding time to an article on varicose veins, but dislike clinics consisting mainly of em. I read with great interest the stimulating contribution

Prof. A. M. Boyd and Mr. D. J. Robertson (Sept. 20, p. 452). I think there are three ways of dealing with varicose veins. The first is that detailed in the above article by tying the "head springs" filling the superficial veins—i.e., the internal or external saphenous veins and their branches and prominent communicating veins. I find this gives good immediate results and the veins often spontaneously thrombose. In two years or so the veins reappear, especially in the leg, and later become troublesome. They have refilled from lesser communicating veins, for the varicose condition is a progressive one.

The second method is to tie the internal or external saphenous veins in one or more places and to inject a

sclerosing fluid down them either with a hypodermic or a long needle. The results of this are also good, even though, as Boyd and Robertson show, some of the fluid goes into the deep veins; massive superficial thrombosis often follows. In my patients some varicosities reappeared in the leg two or four years later, but the trouble was never so acute; most patients were symptom-free.

The third attack is to tie the internal saphenous vein at the groin and ankle and to scarify its interior mechanically by needle with a roughened head and thereby to make as certain as possible that the main stem of the internal saphenous is permanently destroyed by thrombosis and organization. In addition I slowly inject a moderate amount of sclerosing fluid to supplement this action and to permeate into the branches. This method has given the best effects in my hands. I am indebted to Mr. Riddoch, of Birmingham, for the physical abrasion of the interior of the vein.

*Symptoms of Varicose Veins.*—"Are varicose veins a disability? In most cases, in my experience, emphatically yes. A few people do come because of vanity and fear of their parents' suffering but on the whole, since I have inquired before and after operation I am surprised at the inconvenience, pain, itching, weight, tiredness, sleeplessness, incapacitation, and expense they cause, particularly when a recurring complication develops like phlebitis, eczema, ulceration, not to mention refusal of hard work and inferior feelings.

*The Incision.*—I found the vertical one gave a poor aesthetic result and that the transverse one was inadequate sometimes. I therefore combined the two into a "hockey stick" incision beginning externally in the crease of the groin and curving downwards and inwards parallel to the scrotum or labia. Its centre is where a line starting at the pubic spine intersects the groin at right angles. The exposure is perfect and the scar inconspicuous; it is almost a "normal" incision.

*Deep Thrombosis.*—I was aware of the passage of some of the large doses of common salt into the deep veins from the fall in blood pressure which takes place sometimes immediately afterwards as also from the occasional transient haemoglobinuria that followed its use. I still believe that it is quickly diluted into ineffectiveness. I now use a smaller bulk solution called P3G (phenol 2%, glycer 30%, glucose 30%, and gelatin  $\frac{1}{2}\%$ ), 10 ml. each at the groin and ankle. A few swollen legs have occurred in my patients. They have been temporary and only cause discomfort for two to three weeks and none have approximated to a white leg. The moment deep pain or swelling appears dicoumarol, 50 mg. t.d.s., is given and patients are kept about. The understandable impulse to lie up is restrained.

*Communicating Veins.*—I would thank Boyd and Robertson for their precise location by phlebograms of the large communicating veins above and below the knee. They occur often enough as primary sources to make precise diagnosis difficult unless the existence is known. It is on account of their variability in place, number, and size that I aim to permanently destroy the entire internal saphenous from the groin to the ankle. A large communicating vein does rarely require individual ligation. With my patients most have been at the lower third of the leg, just above the ulcer area. I believe the full clearance of the varicose veins of the leg is essential for the permanent relief of dermatitis, eczema, and ulcers. This is one reason for the ligation at the internal malleolus.

*Follow-up.*—Finally, for the perfect aesthetic result (and this the aim in hospital and private), I find that these patients require inspection every three, four, five, or six months, for "tidying-up" injections, for three years.

*Conclusion.*—The personal suffering and impairment of national efficiency due to varicose veins and their complication are enormous and generally unrealized.—I am, etc.,

London, W.1.

HAROLD DODD.

### Road Accidents

SIR.—With reference to road accidents, and particularly a regards the driver's liability, neither in your leading article (Oct. 18, p. 618), nor in Dr. Soddy's paper (p. 623), nor, incidentally, in my own letter which you were good enough to publish (May 17, p. 696) is there any mention of the individual's ability to do more than one thing at a time, or, rather, to follow more than one train of thought simultaneously. Strictly speaking, perhaps this is impossible, but from a practical point of view this mental agility is displayed in very varying degrees. One person will apparently be able to listen to and remember two or more simultaneous conversations, or even play a tolerable

game of bridge while talking or thinking about something quite foreign to cards. The above ability or the lack of it has a great bearing on the making of a good or a bad driver.

Driving is so easy in a well-found car that it is no longer, in most circumstances, a whole-time job. One must perforce think of more than the driving, and it is here that the trouble arises. If one can only do one thing at a time, then when one's mind wanders, which it inevitably will sooner or later, then the driving suffers, and one becomes a potential danger. Many drivers will most of the time unconsciously react correctly to road stimuli, but this unconscious or subconscious reaction is not to be trusted, it is too vulnerable to variations of physical health, alcohol, and other factors.

When one considers such slogans as "Keep your eye on the ball" and "Don't speak to the man at the wheel," it may sound heretical to suggest that in order to be a tolerably safe driver it is necessary to keep only part of one's conscious mind on the business of driving, and to expect more from all drivers at all times is being unreasonable. But I myself would certainly feel safer being driven by a garrulous, agile-minded driver than by one who religiously kept his mind glued to the road, for in the latter case there would be the thought of what might happen when he became unstuck.

It would be both unpractical and undesirable to submit every applicant for a driving licence to a psychological examination; matters are quite complicated enough as it is; but this much could be done without any additional irritation. The car in which the victim is to have his test should be fitted with a wireless set, which the examiner should switch on when the test was under way. Then if subsequently there was any doubt in assessing the driver's capability—that is, if he were a borderline case—he should be asked what he had heard over the wireless while driving, and his ability to answer would sway the decision either for or against. A just-good-enough driver who answered that he was sure he hadn't a notion, he'd kept his mind on his driving, would fail, whereas a similar driver who could give some account of the programme would pass.—I am, etc.,

Thame, Oxon.

E. GRANGER.

### Heparin for Coronary Thrombosis

SIR,—Prof. Lambert Rogers in an article entitled "Advances in Surgery" (*Practitioner*, 1947, 159, 247) cites a remarkable case of pulmonary thrombosis *in extremis* cured or relieved by an injection of 600 mg. of heparin. I suggest that here we have a drug that will prove of incalculable value for promptly treating cases of coronary thrombosis, and that it will save the life of many valuable patients, especially among doctors. It will prevent those most serious ravages to the heart muscle, and give time to treat the underlying arteriosclerosis with a suitable regimen and the use of iodides, etc., for many months. I suggest it should be given after the shock of the attack is treated with morphine, etc.—I am, etc.,

Glasgow.

JOHN T. MACLACHLAN.

\* The use of dicoumarol in coronary thrombosis was discussed in an annotation on Oct. 25 (p. 662).—ED., *B.M.J.*

### Treatment of Neurosyphilis

SIR,—I was surprised to find no mention of the well-known pentavalent arsenical called "stovarsol" in either of the two articles on the treatment of neurosyphilis in the *Journal* of Oct. 11. The drug is less toxic to the optic nerve than trypanamide and has a spirochaeticidal action when given by mouth. On the other hand it may cause rashes and gastro-intestinal disturbances. The alimentary symptoms can be avoided by using bismuth-stovarsol ("bistovol"), which has an additional advantage because some of the bismuth is absorbed.

I have used bistovol by mouth in about 170 unselected cases of G.P.I. prior to malarial treatment and have observed clinical and serological improvement very similar to that noted in the same hospital with penicillin. Moreover, the recovery rate for this series of consecutive admissions was 26% compared with only 10% recovery rate for 200 consecutive admissions treated with trypanamide and malaria. The details of these results have already been published in the *British Journal of Venereal Diseases*, 1945, 21, 174.—I am, etc.,

Lancaster.

R. PAKENHAM-WALSH.

### Pulmonary Haemosiderosis in Mitral Stenosis

SIR.—Dr. Muriel O'Doherty's letter (Oct. 11, p. 587) flatly and frankly disagrees with the pathological interpretations given by Dr. T. E. Gumpert in his interesting article (Sept. 27, p. 488). The correlation of the skiagraphic picture with the morbid anatomy is, as we have already shown (Scott, L. D. W. Scott Park, S. D., and Lendrum, A. C., *Brit. J. Radiol.*, 1947, 20, 100), a difficult enough matter, depending as it does on a correct reading of the morbid anatomy. The detailed histological study of our material (to be reported) does not support Dr. O'Doherty's view that the haemosiderin-laden phagocytes transfer the iron out of the alveoli and lead to hyalinized fibrous nodules in the intralobular stroma.

The striking fact about these cases is the persistence in the alveoli of the siderophores. In the immediately adjoining stromal tissues there is frequently seen iron incrustation of the elastica and the capillary walls, but no obvious haemosiderin, free or in cells, and it would appear as if a high local concentration of soluble iron must occur around the siderophore-filled alveoli. I presume that the fibrous change thereafter occurring in these parts comes to obstruct the lymphatic pathways and so actually prevents escape of the siderophores from the crammed alveoli.

The facts remain that a mitral stenotic showing the obvious skiagraphic picture of haemosiderosis may have an unchanged skiagraph over many months; that microscopically the fibrosis is seen only in the tissues immediately adjacent to the group of filled alveoli; and that despite the presence of many such groups of haemosiderin-containing alveoli there may be scarcely any recognizable iron in the lymphatics or lymph nodes.—I am, etc.,

Dundee.

A. C. LENDRUM.

### Retained Placenta

SIR.—It may interest Dr. Walter Calvert (Oct. 11, p. 589) to know that the method he calls "continuous light cord traction" was used by no less ancient a practitioner than the Father of Medicine himself. A description of the method is given in Smellie's *Midwifery*, the introduction to which, Dr. Smellie says, "contains a summary account of the practice of midwifery, both among the ancients and moderns . . . for the information of those who have not had time or opportunity to peruse the books from which it is collected. . . ." Of Hippocrates he says that he "no doubt availed himself of the observations of those who went before him in the exercise of the same profession." On page 13 of my own copy (edition unknown) comes the following paragraph:

"In the book *de superfoetatione*, after having described the methods of delivering a dead child, he [Hippocrates] says, if the secundines come not away easily, the child must be left hanging to them, and the woman seated on an high stool, that the *foetus* by its weight may pull them along; and lest this should be too suddenly effected, the child may be laid on wool newly plucked, or on two bladders filled with water, and covered with wool, which being pricked, as the water evacuates, they will subside, and the child sinking gradually, will gently draw the secundines away: but should the navel-string happen to be broke, proper weights must be tied to it, in order to answer the same purpose; these being the easiest and least hurtful methods of extracting the *Placenta*."

What a wealth of ancient knowledge and eighteenth-century scholarship is revealed in the introduction to this delightful book!—I am, etc.,

Peaslake, Surrey.

G. I. WATSON.

### Bilateral Abdominal Testes with Teratomatous Change and Torsion

SIR,—I was interested to read the reports of Drs. A. H. Bennett and W. G. Shaw (Feb. 15, p. 256) and Dr. E. C. Chitty (March 15, p. 356), who respectively report cases of seminoma and sarcoma in intra-abdominal testes associated with torsion. It seems to me perhaps that it might be of interest to report a case of bilateral intra-abdominal testes with teratomatous change and torsion of the right testicle.

#### CASE REPORT

At 2 a.m. on Feb. 14, 1947, a Mohammedan missionary aged 34 was admitted to the West London Hospital with a diagnosis of renal colic. He was seen by the house-surgeon, who did not consider his condition warranted a second opinion. On the 15th his

that brought him to the forefront in international neurology. I want only to pay a last tribute to one with whom I was associated in several ways and for whom I came to have so much affection. George Riddoch fortunately retained his boyish enthusiasms, one of which was the unashamed delight that he had in the urbanity and broad outlook of the inhabitants of a great capital. It was traits like this that so endeared him to his friends, gave his personality a more complete significance than could be gathered from his sincere, indeed his passionate, devotion to his work. He should have died hereafter. Even so he leaves behind him a wealth of happy memories for those who knew him and contributions to knowledge that will long survive his day. He was an original thinker with the rare gift of pursuing a problem beyond its first and most easily reached objective.

A friend writes: British medicine has lost an outstanding neurologist. Riddoch was one of the many promising graduates who have left Aberdeen University and attained London distinction. During the first war his appointment to the Empire Hospital for Officers brought him into close touch with nervous disorders, and he became a trusted pupil of such senior neurologists as Farquhar Buzzard, Campbell Thomson, Purves Stewart, and Henry Head. Of the last-named he became protégé and favoured pupil; they collaborated in researches upon spinal lesions which are now classics. Head was instrumental in bringing Riddoch to the London Hospital, which he joined as assistant to the newly formed medical unit. When Head became incapacitated by Parkinsonism, Riddoch was acting as his medical counsellor and intimate friend. From the prosecution of original clinical studies he graduated to an increasing practice which steadily grew to considerable proportions. Leaving Maida Vale for Queen Square, he became famed as a brilliant and stimulating teacher with just that amount of dogmatism which endeared him to students. He was spared the handicap of a mordant wit, but instead was blessed with a rollicking sense of humour and of fun. His striking success as a consultant was due not so much to his considerable abilities as to his personality. He had that rare quality of warmth and kindness, his reassuring smile and open-hearted manner going out to meet the unhappy or anxious sufferer. Riddoch was the most respected British neurologist in France. There he was an especial favourite, his mercurial charm making an appeal to Gallic sympathies, even though he was not a fluent linguist. To juniors visiting France he generously gave personal introductions which, like a golden key, opened all doors in Parisian academic circles. During the war years Riddoch drove himself unmercifully. Caught up as adviser to two Ministries, he instigated, and became chairman of, the Nerve Injuries Committee of the Medical Research Council. Later he was made consultant in neurology to the Army with the rank of brigadier. Despite frustration and disappointment he never ceased to strive for what he knew to be right. For some years his health had suffered gravely, but Riddoch's courage and sense of duty made him keep at his post, organizing the neurological service of the Army. When the war ended, his will power urged him on, visiting his hospitals, teaching, reassembling his disintegrated practice, and attending committees without relaxation or even adequate rest. It was all too obvious that his nerves were becoming strained as harp-strings, but he would not—could not—stop. By his colleagues "wee Georgie" will be sadly missed as a loyal, friendly, and very human personality.

LIEUT.-GENERAL SIR H. FAWCUS,  
K.C.B., C.M.G., D.S.O., M.B.

Lieut.-General Sir Harold Fawcus, Director-General of the Army Medical Services from 1929-34, and of the British Red Cross Society from 1934-8, died at Hillingdon on Oct. 24 at the age of 71.

Harold Ben Fawcus was born in South Charlton, Northumberland, and educated at Durham School and at the University of Durham. He played for the University at both cricket and football for five years, and he also played rugby for Durham County and Northumberland. He graduated M.B., B.S. in 1899, and soon afterwards began his Army career as an attached civil surgeon in the South African War. He was commissioned in 1900 and promoted captain in 1903. Two years later he took the Cambridge D.P.H., and at the examination for promotion

to major in 1911 he obtained a special certificate in state medicine. This led to his appointment in 1912 as assistant professor of hygiene at the Royal Army Medical College, and in 1914 he became instructor at the School of Army Sanitation, Aldershot. He went to France in November, 1914, and from then onwards he devoted himself to medical administration.

He was with the Guards' Division as A.D.M.S. for most of the 1914-18 war, and he was mentioned in dispatches six times, and awarded the C.M.G. in 1915, the D.S.O. in 1917, and also the Croix de Guerre. After the war he was sent to India, but remained there for only a short time. Sir John Goodwin, when he took over the office of Director-General, offered Fawcus the post of A.D.G., and in this capacity he served Goodwin, Sir William Leishman, and Sir Matthew Fell until he himself became D.G., A.M.S., in 1929. The appointment had a four-year limit, but when Fawcus neared the end of his four years an extension was sanctioned because the Warren Fisher committee of inquiry into the medical organization of the Services was still at work. This committee was considering a scheme to revise the status of the college at Millbank and to increase the professional opportunities of R.A.M.C. officers. Sir Harold Fawcus had sponsored this scheme. His one year's extension was cut short, however, when Brigadier-General Hugh Bateman-Champain, Secretary-General of the British Red Cross Society, died. Sir Harold Fawcus succeeded him with the new designation Director-General. Many of the important reforms that he had suggested in 1932 had been brought into effect. The heads of the specialist branches had been concentrated at the Corps College at Millbank as advisers of the D.G., and this new arrangement was working well. His tenure of office with the B.R.C.S. lasted from February, 1934, until 1938, the year in which he became Colonel Commandant of the R.A.M.C.

His appointment as honorary physician to the King dated from 1923, and he was also a commissioner of the Royal Hospital, Chelsea. He was awarded the C.B. in 1928, and created K.C.B. in 1931.

EDWIN ALFRED STARLING, M.B., M.Ch.

Dr. Edwin Alfred Starling died at Tunbridge Wells on Oct. 18 at the age of 90. Dr. Starling was born in North London in 1857, and at the age of 14 he became an articulated pupil to a qualified surgeon-dentist. After four years' apprenticeship he entered Guy's Hospital in 1876. Dr. Starling won the Gurney-Hoare prize and the Beane prize in pathology, and was later clinical assistant at the hospital. He qualified M.R.C.S., L.R.C.P. in 1881 and became obstetric resident and then house-physician at Guy's. After a short period as a ship surgeon, Starling acted as house-surgeon at Coventry Hospital in 1883, and while holding this post he took in 1884 the degrees of M.B., M.Ch. The following year he settled in general practice at Tunbridge Wells, where he formed a local branch of the Surgical Aid Society and, in company with two other Guy's men and a few others, started an eye and ear hospital as well as a natural history and philosophical society. He was on the staff of the eye and ear hospital as anaesthetist from its beginning and was later honorary physician until it was amalgamated with the present Kent and Sussex Hospital. He was then appointed to the combined staff as consulting physician and anaesthetist. Increasing arthritis and loss of sight steadily diminished the amount of work he was able to do, though he fought hard against both afflictions until in 1945 a fractured femur necessitated a long stay in bed. Starling was a member of, and had held office in, the Wesleyan Church and had been engaged in many of its activities. His wife pre-deceased him in 1944, after 58 years of married happiness. Their only son, Dr. E. C. W. Starling, is in practice at Tunbridge Wells.

Dr. Starling joined the British Medical Association immediately after qualification and soon interested himself in its work. In 1889 he was elected to the council of the old East Sussex District of the South-Eastern Branch, and in 1903, on the reorganization of the Association, became the first honorary secretary of the new Tunbridge Wells Division of the Branch, a post he held until 1910. In 1895 he was elected to the council of the old South-Eastern Branch and from 1909 to 1913 was honorary secretary of the Branch and its representative at the Annual Representative Meetings right up to 1928, when he resigned. He was chairman

of the Tunbridge Wells Division in 1910-11, and honorary secretary of the Kent Branch from 1913, the year of its formation, until 1927. From 1927 to 1929 he served on the Council of the Association, and was a member of the Private Practice Committee from 1927 to 1929, and the Medico-Political Committee in 1928-9. When the National Health Insurance Act of 1911 came in the South-Eastern Branch considered it wise to break up into three branches, one each for Kent, Sussex, and Surrey. Dr. Starling was largely responsible for this reorganization, and when it was completed he was presented with a massive silver rose-bowl. Before he retired from the Kent Branch secretaryship a cheque for 100 guineas and a study clock were given to him to mark the end of his fourteen years' service in that capacity.

Dr. Alfred Cox writes: These notes give a good idea of the man Starling was and as I well knew him: a hard worker in any sphere he entered, an enthusiastic B.M.A. man, and a man who was liked and respected by all who worked with him. He could be very persistent in pushing the claims of other people, but I never knew more modesty coupled with so much energy. At 90, when crippled and nearly blind, one must not be too sanguine about being remembered, but I am sure my old friend would be pleased to know that the *Journal* of the Association for which he did so much felt it a pious duty to remind his fellow members, and especially those in the south-east, that there has passed away one of the men who have done much to put the Association into the position it now holds as the indisputable representative of the medical profession in this country.

#### F. K. SMITH, M.B., Ch.B.

Frederick Keiller Smith died suddenly at his home in Aberdeen on Oct. 4 at the age of 67. He received his early education at Robert Gordon's College and proceeded to Aberdeen University, where he graduated M.A. in 1899, and M.B., Ch.B. in 1903. He was house-physician to Prof. Findlay and house-surgeon to Sir John Marnoch, and for a few years he engaged in general practice. He then became assistant surgeon to Sir Henry Gray at Aberdeen Royal Infirmary. At the outbreak of war in 1914 he was R.M.O. to the 4th Battalion of the Gordon Highlanders and was later with the First Scottish General Hospital, with which he served during the remainder of the war, attaining the rank of major. In addition to his military duties, he assumed charge of Sir Henry Gray's ward at the Royal Infirmary while the latter was overseas. On the retirement of Mr. Scott Riddell from the staff in 1919, Mr. Smith was appointed full surgeon, and until he relinquished this charge at the end of 1945 he devoted himself unsparingly to the service of the institution. He was also for many years lecturer on clinical surgery at Aberdeen University. In the recent war he became surgical director of the E.M.S. in the North-Eastern region of Scotland. For many years he was medical assessor and referee in the sheriffdoms of Aberdeen, Kincardine, and Banff. A member of the British Medical Association for forty years, he held many offices, including those of honorary local secretary at the Aberdeen meeting in 1914, and vice-president of the Section of Surgery in 1939. He was a member of the Scottish Committee from 1919 to 1924, and of the Scottish Consultants and Specialists Group Committee from 1934 to 1946. Interested in many sports, he excelled at golf, and was captain of the Royal Aberdeen Golf Club in 1930. "F. K." will be sorely missed, not only for his qualities as a surgeon, not only for his fine judgment and wise counsel, but perhaps most of all for his friendliness and serene and tranquil spirit.—S. G. D.

Dr. TUDOR BENSON EVANS died on Sept. 22 at the age of 59. He was educated at Denbigh County School and Liverpool University, graduating in 1912. He was a house-surgeon, and later house-physician, at the Liverpool Royal Infirmary before taking up a resident appointment at the Denbighshire Infirmary. He was a ship surgeon in the *Lusitania* at one time, and he served with the rank of captain in the R.A.M.C. in the 1914-18 war. Subsequently he practised in Liverpool and in Holyhead, and finally at Prestatyn. He was chairman of the Flintshire Panel Committee, a vice-president of the British Legion, and president of the local T.O.C. and of the Welsh League of Youth.

## Medical Notes in Parliament

Speaking in the debate on the Address, on Oct. 24, Mr. DALTON said there would be no delay in the operation of the National Insurance Act and the National Health Act. Both would come into operation next July. From another source it is learned that the Government proposes that in the Health Services a start shall be made only with urgent capital works.

The King's Speech with which the session was opened on Oct. 21 announced forthcoming legislation to abolish the Poor Law and provide a comprehensive system of assistance for all in need, and also to extend the scope of public care of children deprived of a normal home life.

#### Recruitment and Training of Nurses

Mr. MITCHISON asked on Oct. 23 whether Mr. Bevan could make a statement about the Report of the Working Party on the recruitment and training of nurses. This Report was summarized in our issue of Sept. 13 (p. 426) and was also the subject of a leading article (p. 422).

Mr. BEVAN replied that the views of the nursing and other organizations were being obtained. The Working Party's recommendations concerned long-term policy and could not be expected to produce an immediate increase in the supply of nurses. The Government trusted that hospital authorities would at once examine interim measures to reduce wastage and that they would make the maximum use of married and of part-time nurses, and would build up their domestic staffs to relieve nurses of domestic duties.

## Medico-Legal

### ANTI-VIVISECTION SOCIETIES AND INCOME TAX

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The House of Lords decided recently that the National Anti-Vivisection Society is not a charity and is therefore liable to pay income tax. The Special Commissioners had allowed the Society's claim, unwillingly, feeling that they had to follow the 1895 case in which Mr. Justice Chitty had ruled that the Society was a charity on the ground that its intention was to benefit the community, and that the court should stand neutral on the question whether actual benefit to the community followed or not. The Commissioners appealed to the Court, and Mr. Justice Macnaghten found in their favour, the Court of Appeal confirming his decision by a majority. Some account of the judgment appeared in our issue for Jan. 12, 1946 (p. 72).

Their Lordships (Lord Porter dissenting) held that the overriding test of whether the object of a society was charitable was whether it was in the public interest, and that this question was for the court to answer from the evidence before it, weighing the effect on the community against the purpose of the society as expressed in its stated objects. Having regard to the finding of the Commissioners that on balance the object of the Anti-Vivisection Society was detrimental to the public interest, they held that there could be no ground for saying that it was a charitable object.

Lord Porter in his dissenting judgment said that the object of the Society was the protection of animals from the sufferings believed to be involved in vivisection. That object was, in accordance with the decisions in the "animal cases," charitable. He could not accept the view that, when once an object had been held to be in the class of charities, it was then for the court to hear the evidence of both sides as to whether it was in fact beneficial. The object, in his opinion, did not cease to be charitable even if its success would be gravely injurious to the public benefit.

**Correction.**—Under the heading "Another Carbachol Accident" (Oct. 18, p. 636) we described the fourth fatal accident since the introduction of carbachol into this country in 1941. Our later comment on "moryl," which is a trade mark brand of carbachol, might have implied that this was the preparation used in the recent Sourbridge fatality. This was not the case.

No. 41

## EPIDEMIOLOGICAL NOTES

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Oct. 11.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Poliomyelitis

Notifications of poliomyelitis in England and Wales fell 276 (338). This is a reduction of about 18% on the figure for the previous week. The decline has now been established for six weeks. There was no marked difference in the decline registered in different parts of the country, but it was perhaps more noticeable in the South than in the Midlands and the North.

## Cholera in Egypt

Deaths from cholera continue to number between 400 and 500 each day, and 800 or more new cases are reported daily. Last Saturday and Sunday there were respectively 496 and 471 deaths. So far there have been no cases reported outside Egypt and all the neighbouring Arab States are exercising stringent control over travellers arriving by road, air, or sea from Egypt. The Lebanese Government will no longer admit travellers arriving directly or indirectly from Egypt. The *Manchester Guardian* correspondent says that some experts have suggested that "the worst may be over by mid-November, especially if all the large cities can be kept immune as they are at present.

## Discussion of Table

In England and Wales there was no change in the recent trend of infectious diseases. Further rises occurred in the incidence of measles 383, scarlet fever 230, and acute pneumonia 73, with another fall in the number of notifications of acute poliomyelitis 64 and of whooping-cough 43. Decreases were also observed in the incidence of dysentery 30 and diphtheria 17.

Notifications of scarlet fever are now three times the number recorded six weeks ago when the incidence first began to increase; during the week the largest rises were Staffordshire 55 and Warwickshire 36. The incidence of acute pneumonia, which has been doubled during the past five weeks, has tended to rise more rapidly in the North than in the southern half of the country.

The decrease in the notifications of whooping-cough was contributed by the southern section of the country; in the northern counties a slight rise occurred. The largest increases in the incidence of measles during the week were Yorkshire West Riding 101 and Somerset 46. In both these counties distinct centres of infection were reported, and the largest of these localized outbreaks were: Yorkshire West Riding—Coln Valley U.D. 25, Hebden Royd U.D. 25, Doncaster R.D. 37 and Hemsworth R.D. 23; Somerset—Chard M.B. 15, Yeovil M.B. 55, Shepton Mallet R.D. 13, and Yeovil R.D. 30.

The chief variations in the returns of diphtheria were an increase in Warwickshire 9 and decreases in Durham 8 Gloucestershire 7, and London 7.

Two small outbreaks of dysentery were recorded during the week in Yorkshire West Riding, Shipley U.D. 8, and Norfolk, Blofeld and Flegg R.D. 6. Other large returns of dysentery were Lancashire 12 and London 9.

In Scotland there were large rises in the incidence of scarlet fever 85, dysentery 31, and acute primary pneumonia 29. Notifications of poliomyelitis were 19 fewer than in the preceding week. Three outbreaks of dysentery were notified during the week: Aberdeen county 10, Kincardine county 12, and the city of Dundee 12. In the city of Glasgow the notifications of scarlet fever rose from 49 to 93 and the notifications of acute primary pneumonia from 79 to 96.

In Eire increases were recorded in the incidence of measles 21 and typhoid fever 15, while the notifications of whooping-cough decreased by 14. An outbreak of typhoid fever involving 13 persons was reported from Limerick, Newcastle R.D. Notifications of diarrhoea and enteritis 80 have remained fairly constant during the past three weeks.

In Northern Ireland no large fluctuations were reported in the incidence of infectious diseases.

## Quarterly Returns for Eire

During the June quarter the birth rate was 25.2 per 1,000, which was 1.1 above the rate for the second quarter of the preceding year and the largest rate for any quarter during recent years. Infant mortality was 65 per 1,000 registered births and was 8 in excess of the rate for the June quarter of 1946. The general death rate was 15.0 per 1,000, which was 0.9 above the rate for the preceding June quarter. There were 209 deaths attributed to the principal infectious diseases, 52 more than in the second quarter of 1946. Compared with the June quarter of 1946, deaths from whooping-cough increased by 60 and deaths from measles by 22, while deaths from diphtheria decreased by 14. Deaths under 2 years due to diarrhoea

# Vitamin Therapy—its uses and limitations

## EFFECTS OF VITAMIN B DEFICIENCY

Restricted intake of vitamin B has been shown to produce marked symptoms of moodiness, sluggishness, indifference, fear, decreased mental alertness and physical fatigue.

Factors of the vitamin B Complex have been found effective in many such cases. This, with other experimental and clinical work, indicates the value of an adequate vitamin B intake for preventing mental strain and physical fatigue and for preventing other ill effects of malnutrition which may still occur.

## BEFORTISS B-complex capsules

Also available in Ampoules

Each capsule contains			
aneurine hydrochloride	1.0 mg.	nicotinamide	15.0 mg.
riboflavine	1.0 mg.	pyridoxine	0.5 mg.

### A SUMMARY OF THE ADVANTAGES OF STREPH

- (1) Non-selective.
- (2) Activity is maintained in the presence of proteins.
- (3) Non-necrotic, non-toxic, non-staining.
- (4) Clear solutions with water, normal saline, and alcohol.
- (5) Powerful deodorant.
- (6) Almost odourless
- (7) Powerful detergent and compatible with soap.
- (8) STREPH is approximately three times as effective as Liq. Chloroxyleneol or Iysol.

For these reasons STREPH is the ideal antiseptic for medical, surgical and obstetrical use.

## PHENOXYETOL

THE ANTI-PYOCYANEA COMPOUND

**H**ERE is an important new bactericide and antiseptic. Phenoxyetol (Nipa) is B-phenoxyethyl-alcohol, specially purified and standardised, for use in medical treatment and for pharmaceutical preparations.

Phenoxyetol is effective against certain gram-negative organisms, including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds ... abscesses ... indolent ulcers ... associated with *Ps. pyocyanea*. It should not be used for parenteral injections.

Phenoxyetol is very effective in pyocyanea infections of burns or superficial wounds. It is especially useful in the preparation of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

## The ANSWER to PAIN

Composed of acetylsalicylic acid and phenacetin with the addition of codeine phosphate, Veganin Tablets offer a quick-acting sedative — the answer to pain. As the codeine content in Veganin is minimal, there is no risk of drug addiction and the amount of acetylsalicylic acid and phenacetin is sufficient to be efficacious yet insufficient to cause toxic symptoms.

Supplied in tubes of 10 or 20.  
Boxes of 100 and 500 are  
available for Professional use.

## For Personal Use

# VAPEX INHALANT

Now re-introduced exactly as before in quality and price. The pleasant, unobtrusive aroma of Vapex, its efficacy in the relief of the common cold and as a prophylactic, make it particularly suitable for personal use by the medical profession. A drop on the handkerchief lasts all day.

### COMPOSITION—

Menthol 17.500 Linalyl Acetate 0.468  
Ol. Eucalypt. 4.687 Ol. Lavand. 4.687  
Boreryl Acetate 0.416 Oil Camph. Essent. 1.500 Alcohol (I.M.S.) 70.742

# 'MYANESIN'

*The new muscle relaxant*

**NOW AVAILABLE**

Clinical trials, involving its use in over a thousand cases, have clearly shown the value of 'Myanesin' for the relaxation of abdominal muscles in surgery.

'Myanesin' was discovered in the B.D.H. Research Department. It is an entirely synthetic substance of known and constant chemical composition [ $\alpha$ :  $\beta$ -dihydroxy- $\gamma$ -(2-methylphenoxy)-propane].

'Myanesin' is now available as a 10 per cent. solution in ampoules of 10 ml. issued in boxes of 3 and 12 ampoules.

*Details of dosage and other relevant information on request*

## Prompt relief from pain IN PEPTIC ULCER

Prompt and sustained relief from the pain of peptic ulcer is one of the striking features of medication with 'Aludrox.'

**The medication of choice in peptic ulcer**

### FORMULA:

Aluminium hydroxide 5.6%, Sodium benzoate 0.5%, Oil of peppermint 0.01%, Alcohol (90%) 0.075% v/v, Benzoic acid 0.05%. Distilled water to 100%.

- PROMPT RELIEF OF PAIN
- RAPID HEALING OF ULCER
- FEWER RECURRENCES
- LESS NEED FOR RESTRICTED DIET
- NO ALKALOSIS

JOHN WYETH & BROTHER LIMITED, (Sole distributors for PETROLAGAR LABORATORIES LTD.) Clifton House, Euston Rd, London, N.W.1.

and enteritis numbered 166, a decrease of 18. Deaths from pulmonary tuberculosis totalled 812, and there were 250 deaths from other forms of tuberculosis; these figures were 66 above and 4 below the corresponding figures in 1946.

#### Births during the September Quarter

A further fall in the birth rate has been announced by the Registrar-General of England and Wales. The birth rate rose steadily from the end of the war to a peak of 22.8 in the first quarter of this year, fell in the second quarter to 22.0, and is now recorded as 20.0 per 1,000 population for the third quarter.

#### Week Ending October 18

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,352, whooping-cough 1,009, diphtheria 202, measles 1,797, acute pneumonia 531, cerebrospinal fever 44, acute poliomyelitis 276, acute poliomyelitis 12, dysentery 46, paratyphoid 16, and typhoid 7.

## Medical News

#### Rector of Glasgow University

Mr. Walter Elliot, M.P. for the Scottish Universities, was elected Rector of the University of Glasgow on Oct. 25. The polling figures were: Mr. Elliot (C.), 1,022; Dr. O. H. Mavor ("James Bridie") (Ind.), 521; Mr. Tom Johnston (Lab.), 448; and Mr. David Niven (Ind.), 137.

#### U.S.A. Research Laboratory Burnt

The Roscoe B. Jackson Memorial Laboratory, of Bar Harbor, Maine, is reported to have been destroyed in one of the fires ravaging that region as a result of the prolonged drought. Experimental work on cancer and genetics has for many years been carried on at the laboratory, and animals bred there were distributed throughout the U.S.A. for research purposes. In recent years research at the laboratory has been conducted on the inbreeding of certain strains of rats, rabbits, and guinea-pigs.

#### Return to Practice in Ireland

The Medical Registration Council of Eire points out to medical practitioners resident in Eire that notices in the public press should do no more than notify the patients of absence from home, or return, or change of address. The Council considers that (1) no notice should appear more than once; (2) no title except that of Doctor (Dr.), or Mister (Mr.), or Surgeon should be used; (3) no degree or qualification should be inserted after the name; (4) in no case should hours or days of attendance be specified; (5) the telephone number and full address should be quoted only in case of taking up residence or change of residence.

#### B.M.A. Library

The Association's Library is to be transferred from its present accommodation in the main building at B.M.A. House to the first and second floors of the Garden Court wing. To facilitate the removal, the Library will be closed from 12.30 p.m. on Saturday, Nov. 1, until 9.30 a.m. on Monday, Nov. 17.

#### Chelsea Clinical Society

The first dinner meeting of the new session was held on Oct. 14, with Dr. Neil MacLay in the chair. Mr. Nils Eckhoff opened a discussion on "Surgery in America," and was followed by Sir Heneage Ogilvie. The next meeting will be held on Nov. 11, at the South Kensington Hotel, London, S.W.7.

#### Postgraduate Education

The North London Postgraduate Medical Institute was formed early this year at the Prince of Wales's General Hospital to provide senior postgraduate teaching in medicine and surgery within the British Postgraduate Medical Federation.

#### Resettlement of Disabled Persons

A circular from the Ministry of Health points out that the re-education of a disabled patient and supplying him with general information about resettlement facilities is, in the first instance, the duty of hospital staffs—particularly of the almoner's department. Suitable literature may be obtained from the Disablement Resettlement Officers of the Ministry of Labour. In order to provide D.R.O.s with expert medical guidance on the functional effect of disabilities, medical interviewing committees will be set up at certain hospitals this year; further details will be announced later.

#### Medical Golfing Society

At a meeting held at Deal on Oct. 11 and 12, Dr. W. J. Cotton won the Canny Ryall Cup and Mr. L. G. Brown, M.C., the Milson Rees Cup.

#### National Institute for the Deaf

Speaking at the Annual General Meeting of the National Institute for the Deaf recently, Mr. Scott-Stevenson said that the research laboratory was now in being under the direction of Mr. D. B. Fry, Director of Phonetics, London University. He thought that the Government-sponsored hearing-aid would be available by the target date of July, 1948. It would be good, but there would always be room for the good private manufacturers, who had done such excellent work in the past. Welfare workers for the deaf must be recognized and must receive adequate compensation for their highly specialized job. He ended by welcoming the formation of the British Association of the Hard of Hearing. Mr. Edward Evans, M.P., followed with a plea for research into the sociology and general needs of the deaf, since too many were being put into dull jobs such as boot-mending, cooking, and needlework. He wanted to see a wider field of vocation available.

#### Wills

Dr. John Percy Litt, formerly medical officer of health for the Borough of Lytham St. Annes, who died on May 25, left £51,021. Dr. Charles Gordon Gibson, of Launceston, Cornwall, who died on May 4, left £34,561. Surgeon Rear-Admiral Hamlet Mark Whelan, of the Royal Naval Hospital, Plymouth, who died on May 27, left £2,939.

### COMING EVENTS

#### Long Fox Memorial Lecture

The XXXVI Long Fox Memorial Lecture will be delivered by Prof. G. Hadfield in the large physics lecture theatre (Royal Fort), Bristol University, on Tuesday, Nov. 18, at 8.15 p.m. His subject is "Subacute Bacterial Endocarditis." Admission to the lecture is free.

#### British Association of Physical Medicine

The British Association of Physical Medicine has arranged for the following films to be shown at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C., on Wednesday, Nov. 5, at 5.30 p.m.: (a) The Early Diagnosis of Poliomyelitis, and (b) The New Horizon. The films will be followed by a discussion, with Dr. F. D. Howitt in the chair.

#### Royal Sanitary Institute

A sessional meeting of the Royal Sanitary Institute will be held at Belfast City Hall on Thursday, Nov. 6, at 10 a.m., when there will be a discussion on "The Control of the Manufacture and Sale of Ice Cream," with contributions by Dr. S. Barron, Dr. W. G. Swann, and Dr. G. F. W. Tinsdale.

#### Society of Chemical Industry

Prof. E. C. Dodds, M.D., F.R.S., will deliver a lecture on "Academic Research and the Chemical Industry" before the Manchester Section of the Society of Chemical Industry at the Engineers' Club, 17, Albert Square, Manchester, on Friday, Nov. 7, at 6.30 p.m.

#### The Vicary Lecture

The Thomas Vicary Lecture of the Royal College of Surgeons, on Lawson Tait, will be given by Dr. I. Harvey Flack on Friday, Nov. 21, at 5 p.m. Dr. Flack is Assistant Editor of the *British Medical Journal*.

#### Second Army Medical Services Reunion Dinner

The Reunion Dinner for officers and ex-officers of the R.A.M.C. who served with the Second Army, 1944-5, will be held at Kettner's Restaurant, Romilly Street, London, W., on Friday, Nov. 21, at 7.15 p.m. Tickets, one guinea each, are limited in number, and can be obtained by early application either to Dr. R. Gwyn Evans, 33, Sandford Road, Mapperley, Nottingham, or to Dr. R. F. G. Ormrod, Fountain Court, Temple, London, E.C.

#### Tropical Medicine

The Fourth International Congresses on Tropical Medicine and Malaria will meet in Washington on May 10-18, 1948, under the sponsorship of the Department of State. Over sixty governments have been invited by the Department of State to send official delegations. The officers of the Organizing Committee are: Dr. Thomas Parran, chairman; Dr. George K. Strode and Mr. Clarke L. Willard, vice-chairmen; Dr. Rolla E. Dyer, programme director; Dr. Wilbur A. Sawyer, executive secretary; and Mr. William L. Breeze, secretary. There will be twelve scientific sections covering the following fields: research and teaching institutes, tropical climatology and physiology,

bacterial and spirochaetal diseases, virus and rickettsial diseases, malaria, helminthic diseases, protozoan diseases, nutritional diseases of the Tropics, tropical dermatology and mycology, tropical veterinary medicine, public health, and medical and veterinary entomology. Visits will be made to the National Institute of Health in Bethesda, to the laboratories of the Department of Agriculture in Beltsville, and to other institutions and laboratories in and around Washington. Those interested should write to the Executive Secretary, Fourth International Congresses on Tropical Medicine and Malaria, Department of State, Washington 25, D.C., U.S.A., for the preliminary announcement and the advance registration and hotel reservation form.

#### Australasian Medical Congress

The sixth session of the Australasian Medical Congress (British Medical Association) will be held at Perth, Western Australia, from Aug. 15 to 21, 1948, under the presidency of Dr. D. M. McWhae. The scientific sections of the congress, numbering fourteen, are as follows: Medicine; Surgery; Naval, Military and Air Force Medicine and Surgery; Obstetrics and Gynaecology; Paediatrics; Ophthalmology; Oto-Rhino-Laryngology; Public Health, Tuberculosis, and Tropical Medicine; Anaesthesia; Pathology, Bacteriology, Biochemistry, and Experimental Medicine; Orthopaedics and Physical Medicine; Radiology and Radiotherapy; Dermatology and Industrial Medicine; and Neurology and Psychiatry. The names and addresses of the honorary local secretaries, from whom application forms for membership may be obtained, are: *New South Wales*, Dr. K. B. Noad, c/o British Medical Association, 135, Macquarie Street, Sydney; *Queensland*, Dr. Harold Love, Wickham House, Wickham Terrace, Brisbane; *South Australia*, Dr. J. M. Bonnin, 178, North Terrace, Adelaide; *Tasmania*, Dr. J. P. Millar, 163, Macquarie Street, Hobart; *Victoria*, Dr. Roy F. Watson, 294, Glenferrie Road, Hawthorn, E.2.

#### SOCIETIES AND LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Thursday, Nov. 6, 5 p.m. Bradshaw Lecture by Dr. Janet Vaughan: The Anaemia Associated with Trauma and Sepsis.

#### ROYAL SOCIETY OF MEDICINE

*Section of Epidemiology and State Medicine*.—Monday, Nov. 3, 4.30 p.m. Paper by Dr. E. A. Underwood: History of Cholera in Great Britain; Major-General Sir John Taylor: Current Problems in Cholera Control; Mr. P. Bruce White: Bacteriological and Immunological Aspects of Cholera.

*Section of Orthopaedics*.—Tuesday, Nov. 4, 5.30 p.m. (Cases at 4.30 p.m.)

*Section of History of Medicine*.—Wednesday, Nov. 5, 2.30 p.m. Paper by Dr. H. P. Bayon: Karl Marx (1818-83), his Ailments and Relations with Medicine.

*Section of Surgery*.—Wednesday, Nov. 5, 8 p.m. Presidential Address by Sir Max Page: Surgical Records. Discussion to be opened by Mr. H. Cotton.

*Section of Neurology*.—Thursday, Nov. 6, 8 p.m. Presidential Address by Dr. C. Worster-Drought: Some Observations on Charcot Arthropathy.

*Section of Otolaryngology*.—Friday, Nov. 7, 10.30 a.m. Presidential Address by Mr. Donald Watson: An Account of the Progress in the Treatment of Mastoid Infection and Some of its Complications.

*Section of Laryngology*.—Friday, Nov. 7, 2.30 p.m. Presidential Address by Mr. A. J. M. Wright: Milestones in Laryngology. Paper by Mr. Ian G. Robin: Snoring.

*Section of Anaesthetics*.—Friday, Nov. 7, 5.30 p.m. Presidential Address by Dr. J. H. T. Challis: The Teaching of Anaesthetics to Medical Students.

BRITISH INSTITUTE OF PHILOSOPHY.—At University Hall, 14, Gordon Square, London, W.C., Friday, Nov. 7, 5.15 p.m. Mr. J. D. Mabbott: World Peace and World Morality.

WICK TRUST.—At London Missionary Society, 42, Broadway, Westminster, S.W. Tuesday, Nov. 4, 2.30 p.m. Dr. C. T. Bond: Hospitals and Health Services.

SOCIETY OF HOMOEOPATHY.—At London Homoeopathic Hospital, Thursday, Nov. 6, 5 p.m. Dr. A. Kellner: Artificial Hazards in Prescribing.

LONDON UNIVERSITY.—At Royal Society of Medicine, 1, Wimpole Street, W. Thursday, Nov. 6, 5 p.m. Semon Lecture by Mr. E. D. Davis: Applied Anatomy and Physiology of the Pharynx and Oesophagus.

LONDON: UNIVERSITY COLLEGE, Gower Street, W.C.—Tuesday, Nov. 4, 5.15 p.m. Dr. Bernard Katz: Initiation of Impulses by Electric Stimuli. Wednesday, Nov. 5, 5.30 p.m. Dr. M. H. Pirenne: Physiological Mechanisms of Vision.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W.—Wednesday, Nov. 5, 3.30 p.m. Mr. Arthur Ling: The Health Factor in Town Planning (illustrated).

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—Monday, Nov. 3, 8 p.m. Guest Lecture by Mr. John Gillies: Simpson: A Pioneer of Anaesthesia. Friday, Nov. 7, 8 p.m. Dissertation by Mr. F. Starer: Biochemical Aspects of Growth Control.

#### POSTGRADUATE DIARY

EDINBURGH ROYAL INFIRMARY.—Thursday, Nov. 6, 4.30 p.m. Homan Gillespie Lecture by Prof. T. F. Marrian: The Cori Luteum Hormone.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Tuesday, Nov. 4, 5 p.m. Dr. A. D. Port: Vitamins in Skin Diseases. Thursday, Nov. 6, 5 p.m. Dr. G. Mitchell-Heggs: Erythematous-papular and Erythematous-squamous Eruptions.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, W.C.—Monday, Nov. 3, 2.30 p.m. Miss D. J. Collier: Fac Paralysis. Bell's and other palsies. Nerve grafts. Nerve anastomosis.

LONDON CHEST HOSPITAL, Victoria Park, E.—Friday, Nov. 7, 5 p.m. Dr. R. A. Beaver: Anaesthesia for Thoracotomy.

A lecture and demonstration, with living models, on contraceptive technique, will be given by Dr. Marie Stopes at the Mothers' Club, 108, Whitfield Street, London, W., on Thursday, Nov. 6, at 2 p.m. Applications to attend must be made in writing to the secretary at the above address.

Prof. J. Lhermitte will deliver a lecture in English on "The Relation of Neurology to Psychiatry" at the National Hospital (Queen Square, London, W.C.) on Friday, Nov. 7, at 4.30 p.m.

#### BIRTHS, MARRIAGES, AND DEATHS

##### BIRTHS

BEATON.—On Oct. 17, 1947, at Dumfries, wife of Dr. Donald R. Beat, F.R.C.S.Ed., M.R.C.O.G., a daughter.

COOO.—On Sept. 28, 1947, at Southmead Hospital, Bristol, to Isabel M. (née Wilson), M.B., Ch.B., wife of Dr. William Lawrence Codd, a daughter—Rosemary; a sister for Robert.

MACRAE.—On Oct. 21, 1947, to Dr. and Mrs. J. O. Farquhar Macrae, Chu of Scotland Mission, Ichang, China, a daughter—Meriel Fionnla.

MCERVEL.—On Oct. 14, 1947, to Cathleen (née Hardman), wife of Major McEvel, R.A.M.C., 21, Meredyth Road, Barnes, a son.

RUSHTON.—On Sept. 20, 1947, at Leeds, to Peggy, wife of Dr. J. Rushton, a son.

##### MARRIAGES

SCRIVENER—COMPTON.—On Oct. 15, 1947, at Chichester, Captain John Scrivener, M.B.E., R.A.M.C., to Mrs. Patricia U. Compton.

THOMAS—ANDERSON.—On Oct. 8, 1947, at Northwood Presbyterian Church, Harold Ernest Thomas, M.B., M.R.C.P., to Elizabeth Jenn Anderson.

##### DEATHS

CAMPBELL.—On Oct. 17, 1947, at Guildford, Surrey, William Sibbald Campbell, M.D.

CHARLES.—On Oct. 15, 1947, at Stanley, Co. Durham, while out walking, J. Charles, M.D., aged 82.

CROUCH.—On Oct. 19, 1947, at the Private Wing, University College Hospital, London, W.C., Harold Armstrong Crouch, O.B.E., M.C., M.R.C.S., L.R.C. late R.A.M.C. and Sudan Medical Service.

ELLIOTT.—On Oct. 7, 1947, at the British Military Hospital, Iqbal, Palestine, Alexander McKenzie Elliott, M.B., B.Chir.

FAWCUS.—At Hillingdon, Middlesex, Sir Harold Fawcus, K.C.B., C.M., D.S.O., D.C.L., M.B., late R.A.M.C., Director-General, Army Medical Services, 1929 to 1934, aged 71.

FOSKETT.—On Oct. 4, 1947, at Karama, New Zealand, Walter Foskett, M.D., aged 57.

FRENCH.—On Oct. 11, 1947, at Toronto, George William Henry French, M.D., F.R.C.S., late of Hornsey.

GORDON.—On Oct. 25, 1947, George Gordon, M.B., Ch.B., 8, Woodthorpe Oxford Place, Manchester.

GRANT.—On Oct. 23, 1947, at 44, Southlands Road, Weymouth, John Willi Geny Grant, F.R.C.S.

HALLIDIE.—On Oct. 19, 1947, Andrew Hallidie Smith Hallidie, F.R.C.S., The Guildhall, Cambridge, aged 85.

HARTE.—At 103, Botanic Road, Dublin, Thomas Christopher Harte, L.R.C. and S.I. and L.M.

HINDHAUGH.—On Oct. 9, 1947, Ernest Arnold Hodgson Hindhaugh, F.R.C. aged 42.

HUGHESDON.—On Oct. 17, 1947, Mary Redfern Hughesdon (née Davies), M.B., Ch.B., wife of Dr. P. E. Hughesdon.

LE FLUVRE.—On Oct. 16, 1947, at Keriworth, Capetown, William Philip Le Fluvre, M.R.C.S., L.R.C.P., aged 88.

LUCAS.—On Oct. 21, 1947, Simon Levy Lucas, M.B., Ch.B.

MACCORMICK.—On Oct. 25, 1947, at Le Val, St. Brelade, Jersey, Sir Alexander MacCormick, K.C.M.G., K.B., M.D., F.R.C.S.

MACLEAN.—On Oct. 17, 1947, at 10, Marius Road, Balham, S.W., Charles Forbes Maclean, M.B., Ch.B.

MASON.—On Oct. 12, 1947, at 61, Lower Baggot Street, Dublin, Henry William Mason, F.R.F.P.S., L.R.C.S.I.

PICKERING.—On Oct. 16, 1947, Harold John Pickering, M.C., L.R.C. L.R.C.S.Ed., 48, Canfield Gardens, N.W.

PHILLIPS.—On Oct. 21, 1947, at Davison Children's Home, Danby, North York, Wilfrid Westwood Phillips, M.B., Ch.B., late of St. Margaret's, Twickenham.

PINHOEN.—On Oct. 22, 1947, at Tunbridge Wells, Richard Pinhorn, M.R.C. L.R.C.P., aged 93.

RADCLIFFE.—On Oct. 19, 1947, Frank Radcliffe, M.D., The Grove, Dedham, aged 75.

RIDDOCH.—On Oct. 24, 1947, at the London Hospital, E.1, George Riddoch, M.D., F.R.C.P., aged 58.

STARLING.—On Oct. 18, 1947, Edwin Alfred Starling, M.B., M.Ch., aged 90.

STEVENSON.—On Oct. 16, 1947, in Malta, Surgeon Commander Alec Ki Stevenson, R.N.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Bates on Better Eyesight

**Q.**—W. H. Bates, in a book entitled "Better Eyesight Without Glasses," has propounded the theory that: (a) the prevalent view that errors of refraction are incurable "does not fit the observed facts"; (b) "the lens is not a factor in accommodation and that the adjustment necessary for vision at different distances is affected in the eye, precisely as it is in the camera, by a change in the length of the organ, this alteration being brought about by the action of the muscles on the outside of the eyeball . . ."; (c) correcting lenses (glasses), far from doing anything to improve errors of refraction, are definitely injurious to the eyes; (d) "all abnormal action of the external muscles of the eyeball is accompanied by a strain or effort to see, and that with the relief of this strain the action of the muscles become normal and all errors of refraction disappear . . ."; and (e) by exercises designed to ensure relaxation of the "strain" and the training of the external muscles of the eye, errors of refraction can be cured in a matter of months or a year. Dr. Bates acknowledges that his theories controvert the "practically undisputed teaching of ophthalmological science for the better part of a century" but that he has been driven to his conclusions by carefully established facts. I should be glad to know if the theories propounded by Dr. Bates have ever been seriously tested in this country and, if so, with what results.

**A.**—A detailed criticism of Bates's hypotheses was given in an annotation in this *Journal* on September 13, 1941 (p. 383). As regards the specific points raised here, the following observations are relevant:

(a) Errors of refraction are incurable in the sense that the error remains unaltered in adult life. Hypermetropia is "curable" in childhood in so far as there is normally a decrease in its degree. The onset of myopia in later life from sclerosis of the lens may also diminish the degree of hypermetropia. For the rest the facts observed do fit with the view that errors of refraction are "incurable."

(b) There is considerable controversy as to the mechanism whereby the lens plays its part in accommodation, but there is no doubt as to the fact that the lens is the essential factor in accommodation. The daily experience with aphakic patients who have lost their lens in childhood owing to needling operations, or later in life by extraction, is conclusive of the fact that without the lens there is no accommodation. All patients who have lost their lens, from whatever cause, require a reading correction. The one exception is the high myope who after operation has a near point enabling him to read without glasses. There is no evidence whatever that accommodation is induced by alteration of the length of the eye. This view is of historical interest only, and was held in the eighteenth century.

(c) No one has suggested that glasses "improve" errors of refraction. The view that glasses are injurious to the eye goes back to the beginning of the last century.

(d) The suggestion that errors of refraction are psychological in origin does not lend itself readily to disproof. As for the proof for this contention, it is based on the mode of retinoscopy practised by Bates; it involves a capacity to observe half a dozen or more changes of refraction in the space of a second.

(e) The extension of Bates's unproved theory to psychological treatment is obviously also an aspect not readily disproved.

It would be unfair to condemn Bates's system on theoretical grounds alone. Valid therapeutic systems may have a poor theoretical interpretation. The onus of the proof must, however, rest on its originator, and it cannot be said that any convincing evidence has been brought forward. There is also much in Bates's book, such as the restoration of vision in optic atrophy, which is at variance with accepted views on the subject.

Long before Bates, however, it was recognized that "there were none so blind as won't see." Bates's "exercises" are a

form of psychological treatment for suggestible patients requiring these forms of therapy. Such occasional improvements as were noted in organic cases during the course of Bates's treatment are in all probability instances of remission in the course of chronic relapsing affections like iridocyclitis. It would be strange if such instances did not occur amongst the large number of patients who have undergone Bates's treatment.

### Osteoarthritis of Hips

**Q.**—What are the present accepted treatments for severe osteoarthritis of both hips, with special reference to intra-articular injections of a lubricating fluid into the joint, as advocated by Dr. P. Morris in his book, "Fifty Years in Surgery"?

**A.**—Disabling osteoarthritis of both hip-joints is a formidable and still unsolved problem in therapeutics. Treatment may be classified into non-operative and operative methods. Non-operative methods of treatment include the following: (1) Adjustment of the patient's routine of life in order to allow increased rest and to diminish the strain on the hip-joints. (2) Physiotherapy, in the form of local heat from infra-red radiation, or preferably short-wave diathermy, and measures to build up the normal supports of the hips—that is, the surrounding muscles. (3) Correction of any inequality in leg length due to fixed deformity by appropriate raising of one shoe. (4) Deep x-ray therapy. (5) Intra-articular injections. Treatment by intra-articular injections is under fairly extensive trial at several centres at the present time. Most authorities recommend the employment of solutions of weak acids as being more effective than fluids having a lubricating action. Solutions of lactic acid, of acid potassium phosphate (1%), or of acid magnesium phosphate (1%) are variously recommended. A course of six to twelve injections, each of 20 ml., is given at weekly or two-weekly intervals. The results of this form of treatment are difficult to assess. Most observers agree that they are inconstant and uncertain, but that a proportion of patients do appear to gain some symptomatic relief. A satisfactory response is, however, unlikely to be secured in cases of advanced disease or where a severe degree of deformity is present.

Operative treatment is usually advisable when the disease is of severe degree, provided that the general condition of the patient is suitable. The operations available, in order of increasing magnitude, are: (1) Neurctomy of the obturator nerve and the nerve to the quadratus femoris. This cuts off a large proportion of the pain fibres to the hip-joint, and is suitable when a useful range of movement is still present. This method of joint denervation is popular in some French clinics at present. It is still very much *sub judice*. It is not as effective as lateral chordotomy but it is a much simpler procedure. (2) Osteotomy of the femur at the level of the inferior margin of the acetabulum, as advocated by McMurray. (3) Arthrodesis of one hip with arthroplasty or pseudarthrosis of the other. (4) Arthroplasty of both hips. The last two methods are particularly applicable to cases where movement is greatly restricted or where considerable fixed deformity is present.

### Kapeller-Adler Pregnancy Test

**Q.**—Could you give me details of the Kapeller-Adler test for urinary histidine used as an aid in the diagnosis of pregnancy? How long after conception does this test become positive?

**A.**—The test is preferably carried out on a twenty-four-hour specimen of urine, but failing that the first morning specimen may be used. The urine is treated with a bromide reagent followed by a mixture of ammonia and ammonium carbonate, and the whole is then placed in a bath of boiling water for two to three minutes. The presence of histidine is indicated by the development of a red or reddish-violet colour. If the urine is alkaline it needs special preliminary treatment with 10% sulphuric acid and N/10 potassium permanganate solution. For further details, attention to which is important, reference should be made to an article by R. Kapeller-Adler (*J. Obstet. Gynaec. Brit. Emp.*, 1941, 48, 141). According to this author, a positive histidine test may be obtained as early as the first week after the first missed period, and sometimes even before a period is missed. In threatened abortion and missed abortion the

reaction may be only weakly positive; it remains positive in hydatidiform mole, but becomes negative when pregnancy is complicated by severe toxæmia. False positive reactions are sometimes seen in cases of over-function of the anterior lobe of the pituitary. It is difficult to say how reliable is the test. Kapeller-Adler claims almost 100% accuracy in cases of normal pregnancy, and only a 3% error in non-pregnant women. A few other workers have found it to be 99% accurate in cases of pregnancy, but record an error as high as 15% in non-pregnant women. It has been tried out in many laboratories in this country, and the fact that it has not come into general use and replaced biological tests rather indicates that it is not accurate enough to be of much practical value, or at least that reliable results depend to a large extent on the personal factor in the carrying out of the technique and in the interpretation of the colour reaction.

#### Addison's Disease

**Q.**—Has there been any recent advance in the treatment of Addison's disease? The present treatment consists in administration of extract of adrenal cortex and sodium chloride, but the question of gland implantation has been raised.

**A.**—Desoxycortone has proved a useful alternative to adrenal cortical extract and has two advantages: (1) 1 ml. is equivalent to 10 ml. of extract, and (2) tablets—for example, four of 100 mg. each—can be implanted in the subcutaneous fat of the abdomen and continue to act for some eight months. Recently in the U.S.A. Upjohns has produced a cortical extract from pigs which is said to be far more potent than the cortical extract usually obtained from cattle, in the proportion of one to five. Further, it is qualitatively richer in the glycogen-forming or carbohydrate-regulating hormone as distinct from the salt-and-water-regulating hormone, and this is of particular advantage in those patients with a tendency to hypoglycaemia. As to implantation of actual adrenal gland, this has been tried many times, and occasionally favourable reports are made. Broster recently reported a new technique in which a branch of the epigastric artery is implanted into the adrenal vein of the transplanted gland. However, in practice the method of adrenal transplanting has not come into popular use, and the probability is that it is too uncertain and hazardous.

#### Beeswax in Oily Solutions of Penicillin

**Q.**—Beeswax is incorporated in oily injections of penicillin to retard absorption. What is the fate of the injected beeswax and how does it act?

**A.**—The usefulness of incorporating 4.8% of beeswax in the arachis oil used as a vehicle for penicillin is amply attested by the work of Romansky and Rittman. The result is a very viscous medium undergoing slow dispersal; the contained penicillin is consequently slowly absorbed and exerts a prolonged action. The whole of the vehicle is ultimately disposed of by phagocytosis, and is said to have no injurious effect.

#### Intertrochanteric Fracture of Femur

**Q.**—Is an inch shortening and a right-angled coxa vara recognized as a good result following an intertrochanteric fracture of the femur?

**A.**—While the result described cannot be regarded as perfect, would not necessarily be inconsistent with a satisfactory recovery of function. In an elderly patient such a result could be accepted by most surgeons if it was felt that a better anatomical reduction could be achieved only by operation. Though intertrochanteric fractures invariably unite, the union remains soft for five or six months in elderly patients, and it is during this late period that secondary deformation is likely to occur, resulting in coxa vara and shortening. The only way this can be prevented is by maintaining traction in bed for four or five months; or by subjecting the patient to an extensive operation to apply one of the several methods of internal fixation. As always in old people, it is a question of gaining sufficient function for their needs by a method which carries the least risk to life. In younger patients, however, it should always be possible to obtain a perfect anatomical and functional result by early complete reduction and maintenance of the reduction by internal or external splinting.

#### Antiseptic Effect of Ether

**Q.**—Ether applied to the skin and allowed to evaporate is not actively antiseptic, but to what extent is it effective if a little is kept with a hypodermic syringe in a metal pocket-case?

**A.**—On the contrary, ether, although said to be less effective for the purpose than spirit, does kill extraneous bacteria on the skin. Neither can be depended on to sterilize a syringe. The most that ether can be expected to do in the type of use described is to sterilize the outside of the needle. For reference to further information on the sterilization of syringes see last week's issue (p. 680).

#### Toxicity of Phenobarbitone

**Q.**—What daily dose of phenobarbitone is it safe to give for a prolonged period as a sedative? Does the drug accumulate and if so what are the signs that this is taking place?

**A.**—The only guide to the daily dose of phenobarbitone which it is safe to give as a sedative for a prolonged period is that the maximum pharmacopoeial dose is 2 gr. (0.13 g.). This is a dose for repeated use, and it remains for the doctor to discover, for any particular patient, how often this dose can be repeated with safety. Patients vary a great deal in their susceptibility to all barbitone derivatives. The variation has been determined for one derivative—namely, "sodium amyltal"—and it was found that the most resistant patients require four times as much as the most susceptible ones. It is likely that there are patients in whom 2 gr. of phenobarbitone daily will produce some signs of accumulation, while others may tolerate 6 gr. (0.4 g.) or more daily. Phenobarbitone is excreted very slowly by the kidney and therefore accumulates. The signs of accumulation are dullness and drowsiness; there is also a diminution in the depth of respiration.

### NOTES AND COMMENTS

**Tobacco and Poliomyelitis.**—Dr. R. MONAHAN (Geneva) writes Referring to this subject in "Any Questions?" (Oct. 11, p. 598) this writer, in suggesting immunity for smokers, seems to have got hold of the wrong end of the stick. Tobacco smokers invariably develop the inflamed throat so favourable to infecting children. Nowadays children are brought up in a tobacco-drenched atmosphere irritating their throats, rendering them more susceptible to the poliomyelitis virus. To-day the whole atmosphere of England is contaminated as the result of this filthy habit. It might be interesting to compare respective graphs showing the increase of smoking in the last 30 years and the greater incidence of poliomyelitis.

**Loosening the Piston of a Syringe.**—Dr. S. J. D. ESSER Rustenburg, Transvaal, writes: The simplest way of loosening the piston of a syringe (Aug. 30, p. 358) is to dip the syringe in ice-water. Packing it with ice is apt to crack the glass, as the cold is distributed unevenly, but in every refrigerator there is a tray to catch the water when defrosting. We have to defrost every day to keep the refrigerator in good working order. The tray gets full of icy cold water in which the syringes are dipped and left for an hour or longer. We invariably find that the piston is then quite loose owing to the fact that metal contracts more than glass through cold.

**Addendum.**—We should have indicated in our issue of Oct. 2 that the paper on "Shock in Obstetrics" by Prof. W. A. Scott (p. 647) was read originally at the International Congress of Obstetricians and Gynaecologists held in Dublin from July 7-11 on the occasion of the Rotunda Bicentenary Celebrations.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Author overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. # SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY NOVEMBER 1 1947

## HEARD AT HEADQUARTERS

### The Bill Comes In

New Zealand is sometimes cited as the paradise of the State Medical Service. A letter from a doctor in that country, a copy of which has been sent to Headquarters, shows that there are, if not serpents, a few lizards in the rock garden. To begin with, the New Zealand scheme has led to a greater incidence of illness, whether real or imaginary no one can say. The cost of prescribing in New Zealand, which in 1942 was £200,000, rose in 1946 to £1,700,000. The second point is that under the State scheme there is a greater demand for certificates, particularly to excuse absence from work. And, thirdly, there is the mounting cost to the beneficiaries and the public. The scheme is financed to the extent of about 50% by a levy on wages. The current levy for social security, which embodies the health service, is 1s. 6d. on each £1 of wages earned. This year, out of a total New Zealand budget of £106 millions, £42 millions is being paid for social security; in other words, the amount now spent on social security alone is equal to one-and-three-quarter times the amount of the total New Zealand budget ten years ago. Of the £42 millions, half is found by the wages tax and the remainder by other forms of taxation, primarily by what we should call purchase tax. The term "free medicine" evidently needs a great deal of qualification.

### Dollar Tales

Three stories (with the dollars changed into sterling), all from the U.S.A. The American papers report that a doctor in Indiana has received payment of an account rendered forty-seven years ago. A lady, born in 1899, discovered on the settlement of her father's estate that the doctor's bill for her mother's confinement when she herself was born had never been paid. The account rendered was £2, which she sent forthwith, adding another £1 for the doctor's "patience." Perhaps the only instance on record of the child paying for its own delivery. A provident fund organization in New York the other day was rather shocked to receive a claim for 2,400,000 dollars (£480,000) for a maternity case. Closer examination showed that the subscriber was stationed in China, and that the bill was in Chinese dollars, the American equivalent being 200 dollars, or £40. A surgeon writes in an American medical journal that he had operated on a patient and paid him many subsequent visits. He instructed his secretary to make out the account for £50 for the operation and £5 for each visit, £125 in all. The secretary objected. "The man's a millionaire," she said; "if you charge him only £125 he will think you're no good." The surgeon allowed her to persuade him to increase the bill to £250. A day or two later came a cheque for £500, with the remark, "Thank you, I thought it would be £1,000." The surgeon supposed that the millionaire had doubled the amount set down on the bill, but on his asking his secretary she said, "Oh, Doctor, you are such a poor business man. I doubled the amount again and sent in the bill for £500."

### Medical Students in Conference

Medical students from most of the schools of Great Britain came to Tavistock Square at the week-end for the annual meeting of the B.M.S.A. The Association is now five years old—a

healthy and voluble youngster. It suffers to a certain extent, of course, from its leaders' dropping off year after year to join the ranks of the qualified. Very few seem to remain associate members after qualification. Having spoken as students and thought as students, they resolutely, when the time comes, put away student things. The Association seems to be strongest in the North of England and Scotland, rather less strong in London, and weakest in the Midlands (which for this purpose includes Oxford and Cambridge). But it is full of energy and ambition and is planning an international clinical conference next summer, and a three-day clinical conference at three London hospitals next spring, at which 100 students drawn from other parts of Great Britain are expected. It was explained that the London students, who will be hosts, do not need such a conference, for they can get plenty of inter-hospital experience. For a 2½d. bus fare they can attend a lecture at another hospital, and can even, if they ask for it nicely, go on the ward round. The students showed themselves very anxious not to be thought a political body. Unfounded suspicions of Left-wingedness attach to them. As their president said, when people outside see a body of students demanding certain things they say at once, "Oh, yes, Communists, no doubt." Nearly all thought that they should keep themselves to themselves, not even passing resolutions on Palestine or the atom bomb. As one young student expressed it with charming frankness, "We must show that we are working for one great fixed ideal, and that great fixed ideal is ourselves."

### Angels Unawares

The exchange of medical students between this country and abroad is evidently a work of some delicacy. The able student from University College Hospital who is charged with this task for the B.M.S.A. told his fellow students something of his tribulations. One of them is the receipt, about May Day, of letters from medical students' organizations in certain countries in Central and South-eastern Europe saying how happy they are in the political government of their country, and hoping you are the same. Continental students seem to be more interested in what is going on in Great Britain than British students in what is happening on the Continent. One little difficulty is the assumption, apparently, by all hospital staffs that all students who visit this country from abroad are final-year students. Not long ago twenty Swedish students came over. One young woman who was assumed to be on the point of qualifying was asked to give her opinion at the bedside. She was actually a first-year clinical student, but she managed to make it appear that her imperfect English rather than her lack of knowledge was the reason for her unsatisfactory answers.

### The Headquarters House

The Garden Court wing of B.M.A. House has now been derequisitioned and is being occupied by departments of the Association. The library is moving over to the first and mezzanine floors of the new wing, and thus will have a home more worthy of its possessions. What has hitherto been the reading-room is proposed to be converted into a large committee-room, which can be made at option, by means of partitions, into two smaller ones. It is also desired to extend the common-room accommodation. The completion of repair of all outstanding war damage to the building, except for the unoccupied south

wing, was begun last August. The work was covered by a licence for £7,000 received from the Ministry of Works; but it is already evident that the final cost will exceed this sum, and application has been made for a licence to cover the additional expenditure. How far the intensified embargo on constructional work will operate we cannot say.

### When You Are Old

In last week's *Supplement* (p. 96) certain persons who acted in an advisory capacity during the preparation of *When You Are Old*, the popular edition of the "Report on the Care and Treatment of the Elderly and Infirm," were inaccurately stated to have been responsible for the compilation of this booklet. The booklet was written by Dr. William Edwards, author of the recently published sketch of medical life *The Art is Long*, and the credit for having planned the publication and arranged its production belongs to Mr. John Pringle, the Association's Public Relations Officer.

## OPHTHALMIC GROUP COMMITTEE

A meeting of the Ophthalmic Group Committee of the Association was held on Oct. 24, Dr. O. Gayer Morgan presiding. On the question of compensation for loss of capital value of ophthalmic practices—a question postponed from the last meeting of the committee—the view of the Ministry of Health was that, in so far as consultant and specialist practices might continue to be bought and sold, the National Health Service Act would not prevent the continuance of this custom, and therefore there was no case for compensation. It was pointed out in the committee that, while there would be nothing to prevent the ophthalmic surgeon from selling his practice, such sale would become more difficult.

### Future of the N.O.T.B.

The committee had before it proposals from a joint sub-committee on the future of the National Ophthalmic Treatment Board. These proposals, which were approved, included the organization of the service on a clinic basis, for which purpose a survey of the country should be undertaken, and the reopening of discussions with voluntary hospital ophthalmic clinics with a view to amalgamation or effective co-operation between the two bodies; while the functions of the Board should be to establish and maintain clinic premises, to prepare and keep lists of ophthalmologists and dispensing opticians available under the scheme, and to publicize the scheme. Ophthalmologists and dispensing opticians should contribute to the central administration on the basis of a fixed levy for each patient seen.

Correspondence which had taken place between the Association of Optical Practitioners and the Faculty of Ophthalmologists on the fee for examining cases referred to ophthalmologists by approved societies was referred to the committee. The committee agreed at a previous meeting to inform the representative organizations of approved societies that in its opinion any fee for cases which had already been examined by sight-testing opticians and referred to ophthalmologists should be increased to two guineas, and this was reaffirmed.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*County Borough Councils.*—Barnsley, Gateshead.

*Metropolitan Borough Councils.*—Finsbury, Fulham, Hackney, Poplar.

*Non-County Borough Councils.*—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallsend.

*Urban District Councils.*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

*Scottish Burghs.*—Motherwell and Wishaw.

## JOINT TUBERCULOSIS COUNCIL

On the invitation of the Evidence Committee on Remuneration of Consultants and Specialists, the Council has set down its views on the status and salaries of tuberculosis physicians in the National Health Service. The Council considers that among the specialist officers employed by Regional Hospital Boards should be included a chief administrative and consultant tuberculosis officer, physicians in charge of clinical teams dealing with tuberculosis and their assistant physicians, the medical superintendents of sanatoria, and assistant physicians in sanatoria. Physicians in charge of the clinical teams should hold high qualifications, and their status and remuneration should be identical with those of other consultants—e.g., general physicians. Medical superintendents of sanatoria should at rank with general physicians and receive similar remuneration with the addition of residential emoluments or their equivalent. Assistant tuberculosis physicians should correspond in status and remuneration to assistant general physicians.

The Council has deputed Dr. D. P. Sutherland, Dr. Jam Watt, and Dr. Norman England to attend, if invited, before the Spens Committee to give oral evidence in support of the views.

## Correspondence

### National Health Service

SIR,—Some recent letters have suggested that we may be driven to enter the Service whether it is good or bad. That is an enervating fallacy. *We are in command of the situation.* I am simply declining to operate the Service unless the despotic powers conferred on the Minister are removed from the Act. We can compel him to have it done. The only real danger lest we should be confused by discussing conditions of service and persuaded to enter with the Act not amended in this respect.

Amendment of the Act is the fundamental desideratum. As it is, the Act gives the Minister of Health unlimited power over the medical profession. He can cancel any agreement whether as to hours, pay, or any other conditions of service, and impose new ones whenever he likes; and if you object he can dismiss you from the Service. And you are deprived of the right of appeal to the courts, so you will be in the gutter, for the Act enables him to kill private practice. Powers of this kind are not needed for any good purpose. They benefit no one except those with a vested interest in bureaucracy.

The vital facts for us to keep in sight are, first, that until the Act is amended no agreement is worth the paper on which it is written; and, secondly, that we have it in our power, beyond any question, to defeat this trickery and save our profession from would-be dictatorship.—I am, etc.,

D. PRIESTLEY SMITH.

SIR,—The recent flood of correspondence in your columns from general practitioners leaves no doubt as to what opinion the latter hold about fixed hours of duty as compared with the prospect of a 24-hour shift. The genuine G.P. sees in the forthcoming National Health Service a chance of release from the "blood, toil, sweat, and tears" of a routine which has reduced him or her to a life of abject slavery.

In spite of propaganda to the contrary, I feel sure that, when the Minister of Health launches the new Service next July, I will not require us to remain on call for 24 hours in the day. How then did it come about that, at a recent B.M.A. meeting, a motion tabling the desire of G.P.s for reasonable hours of duty was summarily defeated? To state, as some representatives did, that G.P.s do not desire the Minister to tell them what hours they may devote to work and leisure is just so much hypocritical bunkum, and can only emanate from persons who do not care a fig about the welfare of the G.P. Surely it is patently obvious that, if we do not stress our desires for fixed hours of duty, there can be no choice at all as to what time is devoted to work or leisure under the proposed National Health scheme. What will obtain will be "the mixture as before", i.e., the nightmare of 24 hours' duty per day, seven days a week.

I venture to suggest, Sir, that if a ballot were taken as to the opinions held by genuine G.P.s at least 90% would vote for reasonable fixed hours of duty.

Incidentally, while on the subject of leisure, the abolition of the basic petrol ration will certainly abolish what little relaxation some of us were able to snatch. One would have expected the B.M.A. to take up this question very vigorously with the Ministry of Fuel, but as yet no movement in that direction is apparent, unless some manoeuvring is going on behind the iron curtain which seems to have descended between the hierarchy of the B.M.A. and the profession at large. Is it not time that G.P.s learnt something about the negotiations that have taken place with the Minister with regard to the proposed new State Medical Service?

It must be obvious to any disinterested onlooker that our representatives of the B.M.A. have lost touch with the desires of the "backbone" of the profession—the general practitioners. I for one hold the opinion that the reason for this is that the G.P. is not sufficiently represented on the Negotiating Committee. There are too many representatives who are attached to the Royal Colleges or who are in the fortunate position of being able to leave their "better class" practices in order to spend a few days in London. The rank and file of the G.P.s simply have not got the time (even if they had the energy) to relinquish their practices for a few days in order to voice their viewpoints at Headquarters. Thus, for the most part, they must content themselves with an occasional outburst via the columns of the *B.M.J.* It is useless for the B.M.A. to call for unanimity among the profession unless they are prepared to fight for the viewpoint of the common man who labours therein. If this fact is not realized, the B.M.A. may find, just as certain trade union leaders found, that the rank and file are unwilling to obey the dictates of their leaders when the time for concerted action arrives.—I am, etc.,

N. Wingfield, Derbyshire.

H. FIRMAN.

SIR,—May I again bring to the notice of the B.M.A. that it is high time that a lead was given to the profession regarding the National Health Service? For what are we waiting? The Minister of Health is proceeding rapidly, setting up committees to run a service which has already been refused by a plebiscite and regarding the working of which we know nothing at all. Shall we wait and wait until the Minister has completed all his arrangements and then be told, "What can the B.M.A. do about it? The Service is already in operation."

Can the B.M.A. not advise the doctors that they should not allow their names to go forward to be hand-picked by the Minister before we know all there is to know about the Act and the views of the profession determined by plebiscite? This is not a matter to be trifled with: it threatens the extinction of the medical profession, which has existed as private individuals since medicine became a science, and surely the B.M.A. can say that it officially advises that no action be taken by the doctors in spite of Government pressure until the proposed Service is based on the seven cardinal points upon which the B.M.A. insisted to begin with. Or are these seven cardinal points now out of date?—I am, etc.,

Kirkcubright, Angus.

J. MCINTOSH RATTRAY.

### Working Day in the Services

SIR,—I am in full agreement with the recent correspondence complaining about the wasted working day in the Services, and should now be most interested to read a letter in your columns in support of this gross overstaffing of Service establishments with doctors. I have been in the Royal Navy for nearly two years and for the past year have been stationed at a Naval shore establishment. During the whole of that time it has been for only the few weeks when my senior has been on leave that I have felt my existence here has been really justified, and even then it has been a most easy existence. For the times when my senior medical officer is present he has put in a great deal of thought and imagination in working out for me a full day's time-table, so that on paper my presence here should look justified.

The Service system of having two medical officers on the staff of an establishment with five or six hundred fit young

men and women is bad in that they are a further unneeded expense for the taxpayer and it leads to stagnation of any keen young brain.—I am, etc.,

SURGEON LIEUTENANT, R.N.V.R.

SIR,—Recent letters from R.A.F. M.O.s have drawn fresh attention to the chronic under-employment of the so-called general duties officers of the Forces. To their experiences I would like to add my own.

Of some 18 months' service I have spent over six on leave or in transit for one post or another abroad. Many more weeks were spent with almost nothing to do. Back in England I am now in my busiest post yet; nevertheless I rarely see more than six sick persons a day, most of them such trivial cases that in a factory or a public school the "sister" would have coped with them without the advice of a doctor. With great difficulty I sort out two or three to put to bed so that I may keep a staff of some twenty lads at least partly employed on nursing. My medical work over, I find myself surrounded and frustrated by endless administrative duties.

May I add that, before I arrived, for a short while a local practitioner had managed to see the sick before his 9 a.m. surgery, and the sergeant quite easily coped with the administration. A permanent arrangement like this must surely be possible in many places, and would not only release doctors at present wasting their skill but would also save the country no small sum of money.

Facilities, especially with regard to drugs, are not those of the G.P., and one's practice is so dictated by regulations that there is no doubt that professionally one is neither trusted to treat the sick nor to grade men according to their physical standards. Thus all cases except the most minor are sent to military hospitals, where many literally disappear, so that however interesting they may have been they can never be followed up.

I volunteered for a short-service commission believing that facilities for specialization were granted, but I have not had so much as a reply to three successive applications for traineeship, so am resigning myself to five years of futile redundancy. I hope, however, that this may be a warning to any doctor with the slightest enthusiasm, so that he may think more carefully than I did before agreeing to sign on for so long. And if this be a foretaste of the State Service, Heaven help us all!—I am, etc.,

CAPTAIN, R.A.M.C.

SIR,—May I add to the remarks of your R.A.F. correspondent (*Supplement*, Oct. 11, p. 89) on the subject of the Service M.O. When I qualified I understood that the need for doctors was acute both in civilian and Service fields. There came the time when the need of the R.A.F. appeared the greatest (and this in 1947) and I was "offered" a commission. For over six months I have been the supernumerary M.O. on a station in company with the M.O. I was sent out to release for posting. Thus the distribution on my particular station is one doctor per 400 men. We therefore are maintaining *double* the establishment; and I find it very hard to see just how the community benefits from this example of a National Health Service.

The two general practitioners near by are worked off their feet and have on occasion asked for my help, but, in common with your correspondent, my daily 90 minutes of prescribing for colds, flat feet, and bellyache is spread over the whole day, and I cannot make myself available for more useful work.

The direction of young doctors into the Services at this stage *ad lib.* does a grievous harm to doctor and the community as a whole.—I am, etc.,

FLYING OFFICER, R.A.F.V.R.

### The Country Practitioner

SIR,—May I through your columns draw the attention of the N.H.I. Committee to the plight of the rural practitioner who does all his dispensing? The fee paid us is, I believe, in the region of 3s. per head per year, so that with 1,000 patients the country doctor supplies the drugs and dressings and does the dispensing for £150 a year. With the cost of drugs what they are to-day, plus the purchase tax on them, the purely rural practitioner is subsidizing the N.H.I. to a considerable amount.

Further, his car costs are fantastic and he is in every way at a considerable disadvantage compared with the town practitioner.

tioner, who writes prescriptions and is therefore not affected by drug and dressing costs nor the work of dispensing.

These are but two facts which so far seem to have escaped our negotiators but should receive in the future their attention when terms are arranged for the State Service.—I am, etc.,

St. Osyth, Essex.

R. E. CLARKE.

\*\* The dispensing capitation fee is now 4s. 9d.; before the war it was 2s. 6d.—ED., B.M.J.

### Basic Petrol

SIR,—Would it not be only fair to permit doctors to use their cars for all purposes within a limited number of miles of their homes? In this way members of an overworked profession would be able occasionally to visit friends, go to the cinema or their golf club, and still be available with their cars for any emergency call to a case. As it is it seems probable that doctors will very seldom be able to leave their houses except on professional duty. Surely this privilege could not be dubbed unfair to the rest of the public, who are not at all hours of the day and night on immediate call?—I am, etc.,

Enfield, Middlesex.

H. FORBES PATRICK.

## H.M. Forces Appointments

### ROYAL NAVY

Acting Interim Surgeon Lieutenant-Commander W. A. Burnett to be Surgeon Lieutenant-Commander.

Acting Surgeon Lieutenants P. P. Clifford, J. D. F. Shaw, B. Marsden, D. O. Haines, and F. C. S. Pearson to be Surgeon Lieutenants.

### ROYAL NAVAL VOLUNTEER RESERVE

Temporary Acting Surgeon Lieutenant-Commander M. M. Walker has been transferred to List II of the Permanent R.N.V.R. in the rank of Surgeon Lieutenant-Commander.

### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J. R. Hayman has retired on retired pay. War Substantive Majors D. G. C. Whyte, D.S.O., H. R. Hartnell, and H. W. Whitchee, to be Majors.

Captain G. F. Anderson to be Major.

Short Service Commissions.—Lieutenants S. M. Adye-Curran and W. N. Erskine to be Captains. Captain R. M. Vanreenan, from I.M.S., I.A.M.C. Emergency Commission, to be Captain.

### REGULAR ARMY RESERVE OF OFFICERS

#### ROYAL ARMY MEDICAL CORPS

Colonel D. S. Skelton, C.B., D.S.O., late R.A.M.C., has ceased to be employed and has been restored to the rank of Major-General.

### LAND FORCES: EMERGENCY COMMISSIONS

#### ROYAL ARMY MEDICAL CORPS

War Substantive Major M. Chandra has relinquished his commissions and has been granted the honorary rank of Lieutenant-Colonel.

Short Service Commissions, Specialists.—War Substantive Major A. P. Graeie has relinquished his commission and has been granted the honorary rank of Major. War Substantive Captain G. D. Owen has relinquished his commission and has been granted the honorary rank of Major.

Lieutenants J. Cowie and A. M. Dorey have relinquished their commissions on account of disability and have been granted the honorary rank of Lieutenant.

To be Lieutenants: C. J. T. Archer, A. P. Baker, D. C. Barker, W. S. Bell, P. G. Bevan, B. H. Brock, H. C. Butterworth, J. H. Cameron, J. E. Carlyle, B. N. Catchpole, I. C. Church, H. C. Churchill-Davidson, L. W. Clarke, E. D. Cloughley, P. S. Davis, D. Dencer, E. M. L. Evans, D. M. Garratt, J. S. E. Gilbert, N. A. Gray, H. W. Hall, J. B. Hearn, J. H. Hobson, J. S. Holden, D. A. N. Hovic, R. G. Hughes, A. F. Fairlie, A. M. Huntley, G. A. Jeffery, A. S. Jones, J. M. Jones, K. L. Jones, D. R. Lucas, K. B. Lazarus, H. D. Leggatt, W. A. MacDougall, P. C. MacGillivray, A. M. McKinlay, H. S. McWalter, S. L. Mann, E. D. Marsh, R. Martin, D. G. Miller, R. D. Mills, W. C. Palmer, T. J. Parkinson, H. S. Paul, R. Pilsworth, A. Pines, R. J. Randall, A. H. C. Ratliff, J. S. Rivers, A. Ross, F. Sheffield, D. Stenhouse, I. M. Stewart, J. O. Taubman, J. H. Wallis, C. H. Wheatley, D. Whitehouse, I. C. Wilson.

### WOMEN'S FORCES

#### EMPLOYED WITH THE R.A.M.C.

War Substantive Captain T. M. Ward has relinquished her commission and has been granted the honorary rank of Major.

To be Lieutenants: Ellen M. Knight, Eileen Power, Clare E. Wildeboer.

### ROYAL AIR FORCE

Air Commodore (Acting Air Vice-Marshal) T. J. Kelly, C.M.C., has reverted to the retired list, re-attaining the rank of Air Marshal.

Group Captain (acting Air Commodore) E. D. D. Dickson, C.M.C., to be Air Commodore (Substantive).

Squadron-Leader (Temporary) R. J. A. Morris to be Squadron Leader (Substantive).

To be Flight-Lieutenants: P. H. Blackiston and I. M. Perkin

To be Flying Officers (Temporary): W. D. H. Conacher, I. Emerson, D. G. Jones, H. L. Jones, J. Mackintosh, D. A. McC. J. F. McMinn, A. McNab, J. W. B. Matthews, C. P. Newco and W. Seright.

## Association Notices

### Branch and Division Meetings to be Held

HYDE DIVISION.—At Dukinfield Town Hall, Wednesday, Nov. 3, 8.30 p.m. Prof. R. E. Lane: Industrial Life and the Doctor.

STOCKTON DIVISION.—At Stockton and Thoraaby Hos Bowesfield Lane, Stockton-on-Tees, Monday, Nov. 3, 8.30. Sir Stanford Cade: Radiotherapy, Present and Future.

### Meetings of Branches and Divisions

#### COVENTRY DIVISION

A meeting of the Coventry Division was held on Oct. 14. local scheme for immunization and vaccination was accepted.

Dr. H. N. Gregg was elected to the committee of the Coventry Marriage Guidance Council in succession to Dr. C. F. Turner, who was unable to accept re-election.

A resolution "That, while recognizing that any individual must be allowed to issue certificates in the form he or she wishes, the Division recommend that in general a diagnosis or provisional diagnosis be inserted on certificates issued to patients at their place of employment" was carried.

The Chairman, Dr. H. N. Gregg, G.M., then delivered an inaugural address on "Doctors and Doctoring in Coventry Hundred Years Ago." Discussing the medical world of those times, he pointed out that Pasteur was still a physicist and that Lister still a medical student. Coventry in 1847 was a disease-ridden town of some 35,000 souls, living in 6,000 houses. A death rate of 3,000 had caused the Government to set up an investigation, the report drawn up by a Mr. Ranger resulted in a new water supply being obtained. There were in the city 240 public-houses, 20 do 3 dentists, and 20 chemists. The doctors were not all quacks. There were two dispensaries, the larger of which, the Coventry Provident, was self-supporting, its fee being 1d. per week per patient. For confinements the fee was 7s. 6d. for the midwife, £1 for a doctor—these fees being payable at the time of booking. A doctor's income was about £350 p.a. plus £20 midwifery fees. The other dispensary was the Coventry General, which was absorbed by the Coventry and Warwickshire Hospital—opened in 1838. There were also two lying-in hospitals, and also Fords and Boads pits. Of the doctors in practice the best known was Dr. Nathaniel Traughton, who qualified M.R.C.S. in 1818 and who practised in Coventry for over 50 years, and whose drawings of old Coventry have been collected.

A vote of thanks was proposed by Dr. Rollason and seconded by Dr. Rudland, whose ancestors had practised in Coventry for more than a hundred years.

#### MORPETH DIVISION

A meeting of the Morpeth Division was held on Oct. 10. present were Dr. Spence (chairman), and Drs. Blaiklock, Mr. Hobbs, Stephenson, Macfarlane, McFie, Irvine, Lyon, and McGowan of the Morpeth Division, and Drs. Lowry, J. Brown, and McLellan of the Blyth Division. Apologies for absence were received from Drs. Skene, Dickie, and Pierce. It was resolved to elect Dr. Hobbs as a member of the Executive Committee in place of Mr. Bonar, who had left the district. It was unanimously agreed that Dr. William Stephenson should represent the Division at the Public Relations Conference at Newcastle.

Dr. C. C. Ungley then addressed the meeting on "Some Medical Aspects of Shipwreck." He discussed particularly "immersion foot," which was properly recognized and described only during recent war.

Dr. Stephenson proposed a vote of thanks to the speaker.

#### ROCHESTER, CHATHAM, AND GILLINGHAM DIVISION

A clinical demonstration was held at St. Bartholomew's Hospital, Rochester, on Oct. 9, when about 45 medical practitioners attended and discussed a number of cases.

### RETURN TO PRACTICE

The Central Medical War Committee announces that the following has resumed civilian practice: Mr. A. J. Heriot, F.R.C. 152, Harley Street, W.1 (Welbeck 9030).

## THE PEEP-SHOW

### A NEW TECHNIQUE FOR PURE-TONE AUDIOMETRY IN YOUNG CHILDREN

BY

M. R. DIX, F.R.C.S. AND C. S. HALLPIKE, F.R.C.P., F.R.C.S.

*(From the Aural Department and Otological Research Unit, Medical Research Council, National Hospital, Queen Square, W.C.1)*

In the course of the last eighteen months we have been called upon to examine a number of young children, many under the age of 6 years, with a view to establishing the possible role of deafness as a cause of backwardness in talking. Deafness was already suspected in nearly all of them, and, while in many its existence was virtually established, its extent was still a matter of conjecture. In a few the existence of any significant deafness was still in doubt, and in a few others mental deficiency was suggested as a possible cause of the backwardness in speech. Most of the children had already been examined elsewhere; in nearly all no quantitative assessment of their hearing capacity had been achieved, and it was the pressing need for this which caused all of them to be referred to us by school medical officers and others responsible for their care.

From the point of view of the medical officers the assessment was needed as a matter of urgency, in order that arrangements should be made without delay for any special education which might be required. From the parents' point of view, too, the matter was one of urgency. Although in many of the children the existence of some degree of deafness had come to be assumed, no definite decision had yet been made upon its severity and, in consequence, upon the kind of educational programme likely to be entailed. In all cases this decision was anxiously awaited.

In many instances the children were brought from a distance, and it was therefore important that the deafness assessment should not involve the hardship of repeated visits to hospital. The need, in fact, was for a test procedure which would ensure an accurate measurement of hearing capacity in the course of a single attendance.

Two methods are in common use for the quantitative testing of hearing in adults and older children: speech tests (words or sentences) and pure-tone tests.

Both types of test are very difficult to apply in children under the age of 6 suffering from deafness. Speech tests may sometimes be used in a form which calls for a motor response to a command or invitation, and here it is expedient to address the subject by name; but vocabulary is limited and may be quite lacking, and the tests, though often practicable, are always difficult and the results seldom have the requisite quantitative value.

Tests with pure tones are difficult for two reasons. For most young children the hearing of a pure tone is a meaningless experience. Pure tone audiometer tests, as usually applied, offer only a series of such experiences. It is impossible, therefore, to secure the co-operation of children in the performance of these tests.

There is another and even more serious obstacle to the use of pure-tone audiometry in children. Before the tests are applied it is necessary that the child should be given some explanation of the nature of listening and of hearing. With a child defective in speech and hearing such an explanation, however skilfully given, can seldom be effective. Thus, when the test is attempted the responses are inadequate and irregular, boredom speedily supervenes, further responses become meaningless, and the test has to be abandoned.

The procedure may be further embarrassed by the application of a telephone receiver to the child's head. A head-band is not as a rule well tolerated, and if the receiver is held in position by an assistant frequent small adjustments are needed to prevent serious displacement. These distract the child and fatigue the assistant.

A little experience with the earlier cases in our series led us to conclude that vocabulary defects in the children would prove an insuperable obstacle to the use of speech tests for any quantitative assessment of their hearing which would combine the necessary accuracy and ease of application. We were driven, therefore, to attempt instead the development of a pure-tone audiometric technique that would avoid the two major difficulties to which reference has been made.

It was necessary in the first place to give to the pure tones an arresting significance in the consciousness of the children. In the second place it was necessary to secure their co-operation rapidly and by a method which involved no explanation of the listening process.

By way of introduction to a description of the test procedure which we have been able to develop, something may be said concerning certain well-known features of pure-tone audiometry as practised in the conventional manner, in particular on the functional significance of its results.

#### The Pure-tone Audiogram

In Fig. 1 is shown a conventional type of audiogram. Frequency is plotted along the base line, intensity along the ordinate. Intensity is expressed in decibels above or below the normal threshold value. The decibel intensity scale is a logarithmic one: 10 decibels (1 bel) constitute a tenfold change in intensity, 20 decibels a hundredfold change, and so on. Deafness at any one of the frequencies named is represented by a fall below the zero intensity line at the frequency in question, and normal hearing at all frequencies would thus be represented by a horizontal line at the zero level.

In Fig. 2 is shown an audiogram upon which is inscribed a shaded zone representing the intensity-frequency range

of the speech sounds set up at the tympanic membrane of a listener by a normal conversational voice at a range of 3 ft. (90 cm.). Of this zone, the central portion lying between the frequencies 1,000 and 2,000 c.p.s. is the most important for the understanding of speech.

Now it may be taken that for speech to be readily understood the speech sounds should have an intensity at least 20 decibels greater than that at which they can just be

tone audiogram, whatever its limitations, makes possible a clear answer to the vital question: To what extent is the subject capable of hearing the sounds of ordinary conversation?

If the threshold curve falls below the 60 decibel level at the central frequencies we can say with certainty that the disability is severe, if below 80 decibels that it is substantially complete.

Fig. 1.—Typical audiogram chart.

Fig. 2.—Audiogram showing the intensity-frequency of speech sounds set up by a normal voice at a distance of 3 ft.

heard. Fig. 2 shows that between 1,000 and 2,000 c.p.s. the speech sounds of normal conversation at 3 ft. are some 60 decibels above the normal threshold, and that conversation is therefore heard and understood without difficulty. With a 40-decibel loss of hearing at these central frequencies the 20-decibel margin required for easy understanding of speech is partially lost, and with this degree of loss some difficulty in understanding conversation can often be noticed.

With a 60-decibel loss understanding for conversation is always severely impaired, while a loss of 80 decibels or more is generally considered to constitute a total loss of serviceable hearing. It will therefore be seen that the pure-

### The Peep-show Test Apparatus

The apparatus consists of two parts: one, shown on the left of Fig. 3, consists of a wooden box with a picture at the back well suited to the taste of young children. This picture can be seen through a viewing hatch when illuminated by means of an electric-light bulb, which is also shown inside the box. Above the viewing-hatch is another 8-volt bulb, which can be seen through a shuttered orifice, and above this orifice is a loud-speaker. The bulb is a signal lamp, and is used with the loud-speaker to give synchronized visual and auditory signals in the manner to be described.

Fig. 3.—Diagram of the peep-show test apparatus

This first part of the apparatus is used by the subject, a child, who is seated on a chair in front of the viewing-hatch. In this position the child is separated by a screen from the second part of the apparatus, which is shown on the right of Fig. 3 and is used by the tester. The screen has a hole in it through which the tester can view the subject at a range of some 5 ft. (1.5 m.) or more without himself being observed.

The tester's part of the apparatus consists of a pure-tone generator and attenuator, together with a mains transformer giving an output of 8 volts. The output leads of the tone generator and of the transformer pass to the double rotary switch B, operated by a single handle as shown on the right of Fig. 3. From the switch the two pairs of leads pass respectively to the loud-speaker and signal lamp of the subject's part of the apparatus. These accordingly give synchronized impulses of sound and light when the handle of switch B is rotated by the tester. An additional 8-volt tapping from the mains transformer supplies the illumination bulb in the picture box. The leads reach it by way of two press-button switches arranged in series. One of these, switch A, is controlled by the tester; the other, switch C, is placed by the right hand of the subject near the viewing-hatch. It follows that the picture is illuminated only when both switches are pressed at the same time.

#### The Peep-show Test Procedure

The child is first engaged in play with a few simple toys, and as soon as its co-operation has thus been secured it is seated in a comfortable chair with its face 2 ft. (60 cm.) or so from the viewing-hatch. The position of the child is so arranged that switch C is within easy reach of its right hand. An instructor, whose function is a vital one, sits on the left of the child and focuses its attention, by pointing, on the signal lamp. Meanwhile the tester is observing the child from the opposite side of the screen. The general arrangement of the test procedure is shown in Fig. 4. As soon as he observes that the child's attention is focused upon the signal lamp he rotates switch B and simultaneously presses switch A. Synchronized impulses of light and sound are then emitted from the signal lamp and loud-speaker. The tone frequency used, for this initial signal is 1,024 c.p.s., with an intensity of some 80 decibels above the normal threshold as previously determined by a normal hearing subject with his head in the test position of the child. It will be understood that while this dual signal—auditory and visual—is being given with switch A closed, it is possible for the child, by pressing switch C, to light the lamp inside the box and be rewarded by the spectacle of the illuminated picture.

The first move is made by the instructor (M. R. D.). As soon as the signal appears he leans forward and, ostentatiously pressing switch C, points to the illuminated picture, now visible through the viewing-hatch. This the child scrutinizes with interest. The tester then stops the rotation of switch B and simultaneously opens switch A. The synchronized signals at once cease and the illuminated picture disappears. At this point the instructor withdraws her finger from switch C, indicating by a shake of her head that it no longer works. She then again focuses the child's attention on the signal lamp by pointing. As before, the synchronized signals are again given by the tester. Again the instructor leans forward and presses switch C, and again the picture is illuminated and observed with approval by the child. The signal is then withdrawn once

more and again the picture disappears. By this time the child has usually learnt that the moment to press the switch and be rewarded by the appearance of the picture is when, and only when, the signal lamp is flashing. Consequently, when the signals appear for the third time the child does not usually wait for the instructor to press the switch: instead he leans forward and presses it himself, and usually evinces considerable satisfaction at the appearance of the picture. Once this point has been reached the success of the critical hearing test procedure is assured, and it is then applied. The rationale of this is as follows.

So far as the test has gone, the synchronized light and sound signals will have been seen and, in the case of a child with hearing, heard. The two sets of signals promptly acquire a close association in the child's mind, each announcing with equal effectiveness the time to press the switch. It follows that when one set of signals (the visual) is withdrawn, the other set (the auditory) continues to act. In effect this means that the light signals can now be withdrawn and the test then becomes a test of hearing.

The withdrawal of the light signal is simply effected by closing the light shutter. This is done by the instructor. In the case of a child with a hearing loss of less than 80 decibels the response to the signal, which now consists of sound pulses only, is unchanged. He leans forward at once, presses the switch with unabated alacrity, and again displays his satisfaction with the result. The further steps of the test follow in logical sequence. The tester repeats the signal with rapidly decreasing intensities of sound (20-decibel steps), and a point is quickly reached at which the child fails to respond by pressing the switch. The signal intensity is then raised in steps of 10 decibels until the response again appears. As already stated, the equipment is calibrated for intensity in decibels above the normal threshold in the head position of the child. In consequence, the final threshold reading, which is of course for binaural hearing, can at once be inscribed in terms of decibels of

FIG. 4.—The apparatus in use

hearing loss on the usual audiogram chart. The same procedure is then repeated at 2,048, 4,096, 8,192, 512, and 256 c.p.s. These frequencies are used in the sequence given, and with each the test starts with the light shutter open. With the dual signal the child responds as usual by pressing the switch. The light shutter is then closed and the test proceeds, as already described, as a test of hearing. At each frequency it is usual to change the picture in the box, a simple procedure which is carried out by the instructor. The full test procedure at each frequency seldom lasts more than two minutes: often it is much less. The entire test is generally completed in 10 to 15 minutes. The

children show no signs of fatigue or boredom provided the pictures are changed as described, and the significance of the test results is strikingly shown by the alacrity of the responses and the regularity with which the threshold readings can be repeated.

It is necessary to add a final word of warning upon the need for care in regulating the intensity of the sound stimulus used to begin the test procedure. As described in the text, the figure is given of 80 decibels above normal threshold. In the case of a child with normal or near normal hearing such an intensity would be likely, of course, to prove unpleasantly high, and for this reason its use might bring about a complete breakdown of the test procedure. When, therefore, there is reason for suspecting that the deafness is slight, it is usual to begin with an intensity of 50 to 60 decibels above the normal threshold.

The age distribution of the 31 children tested with the peep-show was as shown in the table below.

Age in Years	No. of Children	Age in Years	No. of Children
2-3	1	5-6	6
3-4	4	6-7	15
4-5	5		

In addition, a few older children were seen with speech defects associated with mental deficiency.

### Selected Case Reports

J. J., a male child aged 2 years 4 months; could at the age of 10 months say "dad," "mum," and "baba." He then had bronchopneumonia followed by frequent colds with a little ear discharge. His speech has since deteriorated, and he expresses his wants by gestures, does not respond to calls or noises, and is thought to be deaf. The tympanic membranes are opaque but intact. There is no response to gong or hooter. He co-operates well with the peep-show, but does not respond at all to sound alone. *Diagnosis:* Hearing absent (or below the maximum intensity obtainable with the peep-show loud-speaker).

R. C. and D. C., uniovular twins aged 11, were low-grade mental defectives and had never developed speech. They were active, played football, and made many inarticulate noises. There were no neurological abnormalities, and psychological tests showed a mental age of 2 years 10 months. There was

FIG. 5.—Audiogram of R. C.

FIG. 6.—Audiogram of D. C.

no abnormality of the ears, nose, and throat. With the peep-show both responded fairly well and gave responses which were very near to normal. Their audiograms appear in Figs. 5 and 6. *Diagnosis:* Speech defect with aphasia; low-grade mental deficiency; hearing normal.

P. M., a girl aged 6, was normal as a baby and babbled freely. She had meningitis at 10 months, did not walk until 2 years, and speech has never developed properly. She attends primary school but is unresponsive, and her teacher thinks it is due to deafness. The girl appeared intelligent but was

FIG. 7.—Audiogram of P. M.

FIG. 8.—Audiogram of J. P.

remarkably shy. She repeated numbers spoken behind her at 1 ft. (30 cm.). No responses were obtained from caloric tests of vestibular function. She co-operated well with the peep-show. Fig. 7 shows her audiogram. *Diagnosis:* Incomplete deafness, probably due to meningitis. She was recommended for a special school.

J. P., a boy aged 3 years 9 months, was normal up to the age of 12 months. He then had pertussis and his speech has not developed properly. An intelligent child, he repeated numbers spoken close to his ear and responded well with the peep-show. (Audiogram, Fig. 8.) Caloric responses of vestibular function were normal. *Diagnosis:* Incomplete deafness due to bilateral neurolabyrinthitis.

R. R., a boy aged 6, was brought by his parents on account of inattention following brief attacks of earache two years ago after measles. Tuning-fork tests showed middle-ear type of deafness. Pure-tone audiometry was attempted and found

FIG. 9.—Audiogram of R. R.

impossible. He reacted well with the peep-show. (Audiogram in Fig. 9.) *Diagnosis:* Catarrhal deafness. Surgical removal of tonsils and adenoids recommended.

### Discussion

The peep-show technique described here certainly appears to overcome the two main difficulties of pure-tone tests in young children. By this we mean that the usually meaningless sound stimuli are given an arresting significance in the child's consciousness, while the still greater difficulties which arise when it is offered an explanation of the nature of listening and hearing are completely evaded by coupling the sound stimulus used to test the doubtful sense of hearing with a synchronized visual signal upon the effectiveness of which full reliance can be placed. In this way the child is induced, with no explanation other than a simple dumb show, to use any hearing it possesses to respond with vivid alacrity to pure-tone stimuli which are accurately controllable for frequency and intensity.

Perhaps the best-known of previous attempts to adapt pure-tone audiometry for use with children is the so-called tunnel test described by Ewing (1930). Its technique was not, however, designed to overcome the difficulty of explaining to the child the nature of the listening procedure, and the test is not stated to have been applied to children under the age of 6 years. Since it was first described no further reports of its use seem to have been published. Perhaps the most striking tribute to the increase in effectiveness of pure-tone audiometry in young children which can be achieved by the use of the peep-show procedure is to be found in a more recent paper in which the Ewings (1944) review very fully their present methods of testing the hearing of children. This paper includes a detailed account of the test procedures used for a group of some 72 children, most of them suffering from deafness, between the ages of 3 and 5 years—the age group in which we find the peep-show procedure to be of particular value. These authors rely chiefly upon drums, pitch-pipes, and spoken voice tests; pure-tone audiometry, applied according to the conventional technique, is not considered as a practical possibility. In this respect their opinion, with which we are in complete agreement, is given in the following terms:

"Pure-tone audiometric tests.—We found that some of the older children among those who proved to be either not deaf

all or partially deaf, like the older children in the war nurseries, learnt quickly to respond to loud or fairly loud pure-tone stimuli, but that they were not interested in listening to such meaningless sounds. The audiometer in itself roused little or no interest and the children's attention was apt to wander. Our experiments showed that except in three or four cases of very intelligent partially deaf children it was not possible to obtain threshold readings."

Pure-tone audiometry accurately applied as by the peep-show procedure certainly yields a quantitative assessment of hearing which is considerably more accurate than anything which can be achieved by means of pitch-pipes, drums, or the spoken voice. In addition, these latter tests also demand for their successful application the services of testers of high skill and long experience. Furthermore, it would seem inevitable that the test procedures must extend, not infrequently, beyond the scope of a single interview.

In contrast, it can be said of the peep-show procedure that great skill and experience are not required. The apparatus itself is simple, and the observational conditions for the tester very good. The responses of the child, too, are quite straightforward and can be inculcated by anyone able to secure his co-operation in simple play. As stated, too, the total time for the test procedure seldom exceeds fifteen minutes, while its results are, with very few exceptions, decisive.

From the administrative point of view there seems good ground for expecting that the peep-show test will prove of considerable value. According to the Education Act of 1944 the Ministry of Education is now called upon to provide special educational facilities for deaf children under the age of 5 years. Children are, of course, not infrequently sent to day schools at the age of 3 or 4 years, and an increasing interest is being taken by teachers and parents in the need for the early recognition of deafness. Young children are therefore likely to be referred in increasing numbers to otologists for confirmation and quantitative assessment of their deafness. No procedure at present in use would appear to possess the accuracy and ease of application of the peep-show test, and in this respect, therefore, we hope that its value will prove to be considerable.

### Summary

A new technique is described which greatly increases the efficiency of pure-tone audiometric tests in young children. By its means reliable threshold curves can be obtained in deaf young children of average intelligence down to the age of 3 years.

The equipment is simple and robust and the test procedure is rapid and easily applied.

Grateful acknowledgments are made to our colleagues at the National Hospital and to others who have referred patients to us for examination.

The Medical Sciences Committee of the Association of Scientific Workers has issued a memorandum on pathology in the National Health Service. It envisages a service covering the whole country, able to perform routine pathological examinations when demanded by medical practitioners and to provide consultants to visit patients in their homes. The service could be extended to more remote parts by means of mobile laboratories. Five to six years' hospital training is suggested for the specialist in pathology, during which time he would take a university diploma or higher degree. The report suggests that academic societies might admit to their membership laboratory technicians who had done good original work. The report concludes by saying that "quite large numbers" of demobilized medical men are being trained as pathologists in a somewhat haphazard way, and that there is a need for the Ministry of Health to indicate the likely demand for pathologists and to establish criteria for their training.

## SOCIAL SURVEYS MEDICAL AND PSYCHIATRIC ASPECTS\*

BY

C. P. BLACKER, D.M., F.R.C.P.

Social surveys make a difficult subject to discuss interestingly and profitably. Descriptions of individual surveys, which perforce deal with problems of sampling and of method, with figures, and with the interpretation of findings, are apt to be difficult to follow, and general principles and conclusions are easily lost in mazes of detail. On the other hand our subject is a large one, extending into many spheres other than the medical. We are here concerned with social medicine and psychiatry. Where is the common ground between these subjects? How is our knowledge of their joint problems furthered by social surveys? How can we discuss this matter most usefully at an international conference?

I shall begin with a word about the evolution of social surveys; I will then pass on to something about medical terminology, which must be internationally intelligible for surveys in different countries to be comparable; and I will conclude with some remarks about the objectives of those surveys which are primarily concerned with problems of health.

### History of Surveys

Medicine and psychiatry are by no means necessarily a primary concern of social surveys in general, though they enter prominently into many and are tacitly recognized as important in most. In their valuable *Bibliography of Social Surveys*,† to which I am much indebted for what follows, Allen Eaton and Shelby M. Harrison bring out the fact that social surveys are essentially developments of the twentieth century. The earliest surveys figure as delayed expressions of a growing awareness of the evils of urbanization. Social surveys in general are attempts at social self-assessment whose beginnings were delayed because, like the individual's strivings towards self-knowledge, they mark the transition from boisterous adolescence to critical maturity.

Throughout the nineteenth century the populations of the United States and of most European countries were rapidly expanding. American towns were extending their range and attracting immigrants from Europe as well as many people from the countryside. The first surveys were inspired by the deplorable conditions which prevailed in towns. An early indication of this awareness in the United States was a book on slum conditions entitled *How the Other Half Lives*, by Jacob Riis, published in 1890, wherein is depicted from first-hand experience the insanitary conditions which prevailed in the most crowded sections of New York; other American works were Lincoln Steffens's *The Shame of the Cities* (1904), the Hull House Maps and Papers concerned with Chicago, and the report of the New York State Tenement House Commission, appointed in 1900 by Theodore Roosevelt. Early and important studies in this country, inspired by a similar concern about how the poor were living in big cities, were Charles Booth's *Life and Labour of the People in London* (1902) and Seebohm Rowntree's *Poverty: A Study of Town Life*, of the year before.

Noteworthy in the history of surveys for its breadth of conception and thoroughness of execution was the survey

\*Read at a joint meeting of Sections of Social Medicine and Psychiatry of the International Conference of Physicians on Sept. 11, 1947, at the London School of Hygiene and Tropical Medicine.  
†Russell Sage Foundation, 1930, New York.

of Pittsburgh, the centre of the western Pennsylvanian steel district. This enterprise was directed by Mr. Paul Kellogg and financed by the Russell Sage Foundation, always a patron of social surveys. The subject matter of this comprehensive inquiry, in Eaton and Harrison's words, "included the study of wages, hours of work, work accidents, and other questions of industrial relations and conditions for both men and women workers; of family budgets and home conditions among steel workers; typhoid fever and other problems related to health and sanitation; housing of the working population; the local system of taxation; the public schools; city planning and civic improvement possibilities; the hospital and other institutional needs of the city; certain phases of the crime situation and the administration of justice; playgrounds and recreation; dependent children in institutions; and a number of other related questions."

The large range of subjects will be noted. Together with industrial conditions, town planning, and housing, the survey comprised sanitary, fiscal, educational, medical, criminological, legal, and charitable activities. Because the survey was planned to effect social improvements which would concern every inhabitant of the town, much attention was given to a matter which tends to be ignored in purely medical surveys—namely, publicity. The chief findings were graphically presented in a public exhibition, and summaries of the various reports, eventually embodied in six volumes, were published in newspapers and magazines; full use was also made of addresses, discussions, and meetings—in short, of both the written and the spoken word.

The idea of turning the social survey into a communal enterprise wherein everyone can participate was carried a stage further in the survey of Springfield, Illinois, carried out in 1914. At that time Springfield contained about 60,000 people and, because of the wide diversity in its economic and social activities, had much in common not only with the other 47 State capitals but also with many other American cities. The enthusiasm which was awakened may be inferred from the fact that seventeen agencies—national and State, public and private—collaborated in the enterprise, a large proportion of the cost of which was borne by the locality. Over 900 citizens participated as volunteer workers, taking part in the field investigations or in the preparation of the Survey Exhibition. An elaborate educational campaign, outdoing in this respect Pittsburgh's exhibition, was also organized. "Those familiar with publicity work," write Eaton and Harrison, "will recognize the value of such things as the invitations sent out by a hospitality committee to mayors throughout the State; exhibit models . . . displayed in public places; unexplained cartoons posted in the windows at Exhibition headquarters; the street railway company's offer to transport school-children free to the Exhibition." Prizes were also offered for the best grammar-school essays on "What I saw at the Springfield Survey Exhibition"; special days were assigned to societies and organizations; and a daily newspaper gave a column entitled "The Survey Question Box."

The Springfield Survey took place in 1914. Looking back over the past 33 years, we discern a civic enthusiasm in these early American surveys which reflects the dynamic quality of these vigorously growing cities. A continent had been subdued by the initiative and faith of early pioneers; vast natural resources lay to hand, waiting to be developed; an abounding spirit of enterprise saw no limits to the perfectibility of the New World. Throughout these early surveys the stress was on the environment of the New World's cities, and it was hoped that the New World's citizens would become perfected with its cities.

Let us not understate the value of the exhibitions, the publicity, and the advertisement given to these geographically restricted surveys. Such surveys are being promoted in England to-day, though for reasons somewhat different from those which prompted the Pittsburgh and Springfield surveys. Here we are now confronted with the many problems of an increasingly congested population endowed with new powers of locomotion. Much excellent publicity was organized for the recent surveys of London. Luto and other provincial towns have held well-publicized surveys. Many of these surveys—that of London for example—are more concerned with problems of town planning and housing and less with sanitary, medical, educational, and psychiatric matters than were the American cities of a generation ago. The medical surveys tend in this small country, to be centrally organized, and in consequence receive little of the publicity which is accorded to geographically restricted enterprises by the civic authorities which has local roots. Indeed the absence of publicity accorded to, and the general indifference to the recommendations contained in, many excellent medical surveys and reports recently produced in this country have been the subject of comment by at least one experienced outside observer.

### An International Medical Terminology

I have already remarked that psychiatric terminology must be internationally intelligible for the results of psychiatric surveys in different countries to be comparable. The movement towards international understanding has borne fruit in medicine in the "International Statistical Classification of Diseases, Injuries and Causes of Death" which is now in preparation. This joint enterprise should be specially welcomed by psychiatrists because of the confusion of the diagnostic nomenclature of psychiatry. There is no sphere where terms become more rapidly pejorative and obsolescent. In 1890 the Lunacy Act was passed in this country; but now the word "lunacy" is banned. The word "asylum," French *asile* (an appropriate word meaning a place of refuge), is now so charged with sinister implications that it too is banned. Euphonious terms with impressive roots in Greek and absurd connotations—melancholia, hypochondria, hysteria, etc.—have dubious reputations and short lives not only because they become pejorative through their association with the feared condition of lunacy, they are also found wanting by advancing knowledge. It was because of clinical experience that "dementia praecox" yielded place to schizophrenia. Other terms, now reputable, may be thrown overboard especially those with wide meanings covering diverse syndromes which may respond differently to new treatments. I may be wrong, but I give a short life to a term like hysteria, which embraces heterogeneous clinical conditions and is likely to be broken up as further knowledge is gained.

In the stresses of war, moreover, new euphemisms, such as shell-shock (1914–18), are invented to facilitate the honourable disposal of good men who have broken down under severe strain. But when the wars are over these words come to be applied to men who have never experienced any but the most commonplace stresses; the words become abused, lose their original meanings, and are banned. The same is now happening to terms like "battle exhaustion" and "flying stress" (1939–45). The innocent word "mental" (from *mens*, the mind) is acquiring unpleasant connotations; so is the awkward word "psychiatrist," about which there are unkind jokes. It would be interesting to know if in other countries and other languages the useful lives of psychiatric terms are as short as they are here.

The attempt to assimilate the conditions of hospitals for mental with those for physical illnesses may reduce the still widespread fear of mental diseases and therefore retard the turnover of psychiatric terms. The international classification may also give to these better prospects of life.

If, moreover, psychiatrists in one country are to profit from surveys conducted in other countries the question of terminology becomes important. This fact became clear to me when, fourteen years ago, I was asked to prepare a report for the Brock Committee on Voluntary Sterilization. How much mental defect, I had been asked, would be preventable if all defectives ceased to have children? There were several relevant investigations reported in German and English. It became clear, however, that the terms used in the two languages ("Oligophrenia" in German and "mental defect" in English, as well as some of the terms denoting grades of defect) covered different ranges of abnormality. Since the milder forms of defect are the most strongly familial, and since the German term "Oligophrenia" has a wider upward range than the term "mental deficiency" as interpreted under our Mental Deficiency Acts, the German literature gave a somewhat different impression from the British of how far mental deficiency would be reduced if all defectives ceased to reproduce. Prof. Strömberg has drawn attention to how the proportions of abnormal persons found in regional surveys of mental abnormalities vary with the latitude accorded to certain diagnostic terms; and in his survey of the island of Bornholm he drew comparisons between his own figures for hospital cases and those of New York and Sweden.

If, therefore, an international classification is to serve the purpose for which it is devised, two things are necessary: first, that the list of approved terms should be subjected to revision at regular intervals, and, secondly, that where the terms are ambiguous some description should be given of the clinical conditions they are intended to cover. Arrangements have been made for meeting the first of these needs. The World Health Organization has appointed an interim Commission to which suggestions for improvement of the "list of categories" can be sent at any time. Indeed, the Interim Commission will at regular intervals ask for such suggestions. The second of the above-mentioned needs—that ambiguous terms should be supplemented by brief clinical descriptions—has been partly met by a decision to assemble many of the psychiatric terms in general or occasional use in an alphabetical index that would show under which number in the approved classification each of the terms should be listed. Such an arrangement would go far to meet difficulties arising in countries speaking the language in which the approved classification and the alphabetical index was prepared. But I doubt if it would be helpful to countries speaking other languages. The psychiatric idioms of English-speaking countries included in the alphabetical list might be difficult to translate into Russian, Hungarian, and Chinese. I see only two ways out of the difficulty. The first is that medical committees in countries speaking other languages than English—the language of the International Classification—should prepare their own alphabetical lists of current diagnostic idioms to fit in with a translated version of the International Classification. The second, and surely simpler, way out of the difficulty is to append to certain key terms in the International Classification short and succinct descriptions, readily translatable into other languages, of the clinical conditions which the terms are intended to denote. In the light of these short descriptions, idiomatic terms in different languages would then be assigned to their appropriate heading and number in the international list.

I have it in mind that the international list might be reproduced in a series of separate pamphlets corresponding to the different sections or specialties, and that in these pamphlets the key diagnostic terms should, where appropriate, be elaborated as suggested above. The International Classification of 1947, which by design can be further differentiated, is a somewhat massive document. It has room in all for 10,000 diagnostic items, not all of which have in fact been formulated. Numbers 3,000 to 3,300 are reserved for the psychiatric classification. These three hundred or so psychiatric terms, together with an alphabetical index of other currently used terms not included in the classification or in a supplementary "Tabular List," might be published as a pamphlet to be used by psychiatrists. The same could be done for neurology, cardiology, dermatology, etc. Armed with translations of such a (comparatively speaking) wieldy document, specialists in different countries could be assured of some common understanding as to usages. I wish to thank Dr. Percy Stocks for information on some of the matters mentioned above, though he is not to be associated with any of the conclusions reached or suggestions put forward.

### Objectives of Surveys

I now turn to my third theme—namely, the objectives of surveys concerned with health. Such surveys may be of local origin and circumscription, or they may be centrally initiated and designed to cover the whole country. It is probably true to say that most local surveys are indirectly concerned with health. Every town-planning and housing scheme has as an objective a healthier population. But the concern with health may be direct, as in surveys initiated by medical officers of health. Centrally initiated surveys are more likely to be organized in a small country like Great Britain than in large ones like the U.S.A. or the U.S.S.R. We can also distinguish between single, periodic, and continuous surveys. Prof. Strömberg's survey is an example of the first kind; a decennial census is an example of a periodic survey, and so perhaps is Dr. E. O. Lewis's in that a survey bearing comparison with his was made twenty years previously; and the process of notification of diseases, admitting of the publication of regular periodic returns covering the whole country, involves a continuous survey.
